The study used, for the first time in linguistic fieldwork involving extensive interviews, a proper sampling procedure. It drew on an earlier sociological survey of the Lower East Side of New York

City conducted by a sociological research group. The original survey used a random sample of 988 adult subjects representing a population of 100,000. Originally aiming to interview 195 of those respondents who had not moved house in the previous 2 years, Labov managed to reach 81 percent of these. Interviews were conducted on an individual basis (see Sect. 4) and involved four types of activity: (a) the main part consisted of continuous speech in response to the interviewer's questions; (b) reading of a short passage; (c) reading lists of words containing instances of pertinent variables; and (d) minimal pairs involving variables (e.g., the vowels in *god* and *guard*, which both have the vowel /ɑ:/ in New York City English). Moving from (a) to (d) clearly corresponds to increasing formality and focus on language itself. At the stage of analysis, sections of the continuous speech were assigned to the subcategories 'formal' and 'casual,' depending on the interviewee's responses.

In grouping his speakers, Labov used a 10-point socioeconomic scale, devised earlier by the sociological research group. It was based on three equally weighted indicators of status: occupation of breadwinner, education of respondent, and family income. On the 10-point scale, 0–1 was taken as lower class; 2–4 as working class; 5–8 as lower middle-class; and 9 as upper middle-class. Of the many variables examined by Labov, postvocalic (r) will be concentrated on here. For contrast, however, the use of (th) will be examined first.

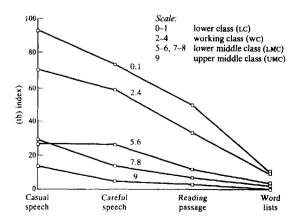
The main variants of the (th) variable—that is, the initial consonant in words like *thing*—are the general American interdental fricative [θ] and less prestigious variants: the affricate [t̪θ] and dental stop [t̪]. These are scored as 0, 1, and 2, respectively. Figure 2 shows the stratification of this variable according to class


Figure 2. Social stratification of the (th) variable in New York City (after Labov 1972a).

and style for 81 speakers. The vertical axis is a scale of average (th) index scores per socioeconomic group; while the horizontal axis represents the four contextual styles. The scores range from a possible 0 (for fricatives only) to a possible maximum of 200 (for stops only).

The graphs show that the greatest occurrence of nonfricative forms is in casual speech for all groups, with decreasing frequency when moving through the more formal styles. There is a stable pattern insofar as the graphs for each class are roughly parallel (apart from the equal LMC and UMC scores for casual speech). Defining the (th) index in the way that Labov did yields a monotonic-decreasing relationship between social class and the (th) variable. That is, an increase in social class or status groups is accompanied by decreasing index scores for (th). The variable may be characterized as sharply stratified, since there is a relatively large divide between the LC and WC groups as against the MC groups.

Turning to postvocalic (r) as used by the same speakers, with a scoring system of 1 for use of [r] and 0 for its absence, and an additional style drawing on minimal-pair lists, Labov arrived at the patterns shown in Fig. 3.

The patterning of (r) shows the following tendencies:

(a) There is fine rather than sharp stratification of the variable—that is, the divisions between the social classes are not as great as for (th). New Yorkers ranked on a hierarchical scale by nonlinguistic criteria follow the same scale in (r) usage.

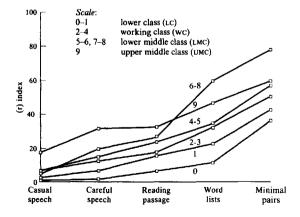
(b) The differences between the groups are not categorical; that is, no group is characterized by the complete presence or absence of postvocalic /r/.


Figure 3. Social stratification of the (r) variable in New York City (after Labov 1972a).

(c) Nevertheless, at the level of casual speech, only the UMC shows a significant degree of r-pronunciation. The other groups range between 1 and 10 percent on this variable. It can be said that in everyday life, the pronunciation of postvocalic [r] functions as a marker of the highest-ranking status group.

(d) All groups show an increase when moving from informal to more formal styles.

(e) As one follows the progression toward more formal styles, the LMC shows a greater increase in the use of [r], until in word-list and minimal-pair styles they overtake the UMC averages.

Labov termed this last phenomenon 'hypercorrection.' The LMC overshoots the mark and goes beyond the highest status group in its tendency to use the pronunciation considered correct and appropriate for formal styles. In this sense, hypercorrection is not the sporadic or irregular treatment of a word class as is the case in second-language or dialect acquisition; rather, it denotes the movement of an entire word class or phonological sequence beyond the target set by the prestige model. This crossover pattern differentiates the (r) variable from the stable (th) variable; Labov advances the hypothesis that this crossover pattern, coupled with differential scores in the various age groups, is an indication of sound change in progress (see *Sociolinguistics and Language Change*).

Labov demonstrated the claim that LMC speakers have the greatest linguistic insecurity by using subjective-reaction tests. In one of his experiments, subjects were asked to rate a number of short excerpts on a scale of occupational suitability (that is, whether the speaker would be acceptable as a secretary, television personality, factory worker, etc.). The tape contained 22 sentences from five women readers in random order. As these were taken from the reading passage, subjects were already familiar with the material. All subjects between 18 and 39 agreed in their subconscious positive evaluation of [r] usage, irrespective of their own level of use of the variable. This was arrived at by rating as 'r-positive' a reaction which assigned to a speaker a higher occupational position for a sentence containing postvocalic [r], than (unknowingly) for the *same* speaker on a sentence where postvocalic [r] was absent. The percentage of r-positive responses of subjects between the ages of 18 and 39 years was 100. Subjects over 40 showed a mixed reaction in their social evaluation; but the LMC speakers showed higher r-positive responses than the UMC. Generally, members of the highest and lowest status groups tend not to change their pronunciation after it becomes fixed in adolescence; members of middle-status groups may do so, because of their social aspirations. The great linguistic insecurity of the

LMC leads to especial fluctuation in formal speech contexts: hence Labov's claims about the consistency of vernacular speech over other styles.

The New York study showed two aspects of sociolinguistic stratification: linguistic differentiation and social evaluation. Labov remarks upon the uniform evaluation of linguistic features such as (r) by New Yorkers as a single speech community, despite the increasing stratification in speech performance.

It is necessary to distinguish between linguistic variables of several types, since not all of them show the stratification and style-shifting characteristic of (r). 'Markers' are those variables like (r), which show stratification that defines the speech community, which all members react to in a more or less uniform manner, and which is subject to style-shifting. Markers contrast with 'indicators,' which show differentiation by age or social group without being subject to style-shifting, and which have little evaluative force in subjective reaction tests. Only a linguistically trained observer is aware of indicators. Examples are the merger of the *hock* and *hawk* vowels in New York, and the use of positive *anymore* in Midland USA (e.g., *That's the way it is with planes anymore*). 'Stereotypes' are forms that are socially marked—that is, they are prominent in the metalinguisic awareness of speech communities, as in the case of 'h-dropping' in Cockney and other English dialects, or the stigmatization of the *toidy-toid street* 'thirty-third street' pronunciation of New York speech (based on an older vowel [ə']). Judgments that bring about stereotypes are not necessarily phonetically accurate, and stereotypes may live on in folk linguistics long after the stigmatized forms have changed. The stigmatized New York vowel [ə'], for example, is not the same as [ɔɪ]: *bird* and *Boyd* are not homophones, except to outsiders.

The issue of prestige is generally an important—and complicated—one in sociolinguistics. Labov distinguished between 'overt' and 'covert' prestige. The former refers to positive or negative assessments of variants (or of a speech variety) in accordance with the dominant norms of the public media, educational institutions, and middle-class speech. In the New York City studies, interviewees who used the highest degree of a stigmatized feature in their own natural speech showed the greatest tendency to stigmatize others for their use of the same form. On the other hand, the stability of working-class speech norms calls for other explanations, since these speakers did not, in fact, readily adopt middle-class norms. 'Covert prestige' refers to this set of opposing values implicit in lower- and working-class lifestyles, which do not appear in conventional subjective-reaction tests. (It will be seen that the New York City pattern has not always been replicated, and that the notion of

prestige is more complex than allowed for in this early formulation.)

Generally, the New York study showed that socioeconomic differentiation cannot be ignored in studies of language structure. Change originates in specific subgroups of a speech community (in this case, the highest-ranking subgroup). The behavior of each class in different styles does not involve random switching. The character of (r) as a prestige feature within the linguistic system can only be gauged within the network of stylistic and social inequalities.

4. Fieldwork Methods

The variationist school stresses the importance of the collection and analysis of a corpus that adequately represents the speech of members of the community under study. Labov was perhaps the first to exploit fully the invention of the tape recorder for socio-linguistic purposes. Labov's attempts to ensure representative sampling of the New York community under study have already been discussed. In practice, sociolinguistic surveys are based on anything from 40 to 150 speakers. Samples going beyond 150 individuals tend to increase data-handling problems without a significant gain in analytic insights. Stressing the need to study the vernacular in its social context gives rise to what Labov termed 'the observer's paradox': the vernacular, which the linguist wishes to observe closely, is the very style which speakers use when they are not being observed. This is akin to the experimenter effect of other disciplines, and the need to ensure that the data which one collects are unaffected by the process of investigation. Labov has used a variety of techniques to get around the problem, the most favored being the sociolinguistic interview. This involves a tape-recorded, personal interview lasting about an hour per person. The session is designed to be as informal as possible in an attempt to defuse the relative status of participants (usually middle-class researcher versus the other). Identification of the interviewer with the teaching profession would invariably typecast him or her as the one from whom information flows, rather than the other way around. The counterstrategy of the sociolinguistic interview is to emphasize the position of the interviewer as learner (about local ways and attitudes), and hence in a lower position of authority than the person to whom the interviewer is speaking. Interviewees are encouraged to talk about everyday topics of personal interest, and thus to take the lead during some parts of the interview. Successful topics often center around childhood games, accusations of blame for things one may not have done, family, religion, dating, and the opposite sex. The most famous one has come to be known as the 'danger of death' question. Interviewees are asked to talk informally about their most frightening moment, when 'you thought you were in serious danger of

being killed—where you thought to yourself, "This is it."' Speakers embarking on such a narration often become so involved in it as to be temporarily diverted from the act of being interviewed. Their speech consequently shows a marked shift away from formal style to the vernacular.

Labov stressed that interview speech should not be mistaken for intimate vernacular style. However, by using an empathetic approach and the right techniques, it brought one as close to the vernacular as was possible, while still obtaining large quantities of comparable and clear data. Among the 'channel cues' that signify a relatively successful interview are modulations of voice production, including changes in tempo, pitch, and volume, alternations in rate of breathing, and occasional laughter. Regarding fieldwork ethics, surreptitious recordings are generally considered undesirable. Gains in gathering natural speech via a concealed tape recorder are usually offset by the accompanying poor sound quality. Furthermore, such deceit may negate good relations necessary for long-term contact with a community.

The individual interview is not the only technique advocated by Labov, who has used a variety of other methods for other purposes.

First, participant observation of adolescent gangs in Harlem, together with other fieldworkers, formed an important database for the study of Black English vernacular. The significance of adolescent gangs lies in the naturalness of these self-selected groups and the checks (conscious and subconscious) by members on any individual who produces nonvernacular forms solely for the benefit of the tape recorder. Some sessions resembled a party rather than a discussion with outsiders. By using separate-track recordings in several group sessions, the researchers obtained clear, varied, and voluminous data which informed their study of sociophonetic variables, syntax, narrative, and adolescent street culture.

This approach was refined by Milroy in the Belfast studies (see *Social Networks*), and by Labov in the long-term neighborhood studies in Philadelphia. The neighborhood studies were designed to obtain a large amount of linguistic and social data on the major social networks of different neighborhoods. Participant observation in Philadelphia has allowed unlimited access to the linguistic competence of the central figures in individual networks, and group recordings which elicit close to vernacular styles. Included in the neighborhood studies are systematic sociolinguistic interviews developed along the earlier New York City models. These remain the best source for comparable data on all members of a social network. Labov's later work thus moves away from an emphasis on a random sampling of a large community to judgment-

sample selection of neighborhoods for intensive study.

The second method involves rapid and anonymous surveys. In certain strategic locations such surveys enable the study of a large number of people in a short space of time, provided that the social identity of the subjects is well defined by the situation. Labov's pilot study of (r) in New York department stores (which preceded the full-scale study discussed in Sect. 3) is a paradigm example. Employees of three large department stores were asked for directions for an item that was predetermined to be on the fourth floor. The reply would therefore contain two tokens of the (r) variable, in two linguistic contexts (before a consonant and at the end of a word). By pretending not to hear the reply the first time, Labov obtained another two tokens in deliberate style. The variable of class/status was built into the study on the hypothesis that departmental assistants tended to approximate (or accommodate to) the speech associated with their customers—the three stores were sharply stratified in respect of their clientele. This simple (and amusing) study showed significant variation in rhoticity (pronunciation of postvocalic /r/) according to linguistic context, speech style, and social class associated with each store. The results were even more finely grained—for example, on the quieter and more expensive upper floors of the highest-ranking store, the percentage of [r] was much higher than amid the hustle and bustle of the ground floor.

The third method involves telephone surveys: in later work, Labov complemented the intensive but nonrandom neighborhood studies by broader (and shallower) representation using a telephone survey. Subjects chosen by a random sample participated in a 15-minute telephone interview, which included some spontaneous conversation, wordlists, and minimal pairs. The emphasis was on communication in Philadelphia, with reference mainly to telephone speech, and special words and pronunciations in the Philadelphia dialect that might be sources of misunderstanding.

Finally, Labov has used a variety of field experiments to tackle specific problems. The subjective evaluation test cited above is but one instance of these.

5. Syntactic Studies

Although the most salient sociolinguistic variables are usually phonological in nature, there are a number of studies of dialect syntax informed by variation theory. Labov's work on Black English syntax was an important contribution to the difference–deficit debate of the 1960s in American education. Working on the assumption that the English dialect of black pupils entering schools contained numerous linguistic deficiencies, compensatory

education programs attempted to eradicate nonstandard forms in favor of the standard equivalents. Labov's contribution was to point to the shaky linguistic underpinnings of the deficit hypothesis. In a careful examination of certain aspects of Black English vernacular (BEV) syntax from a sociosystemic perspective, he demonstrated that what was taken to be a deficit (e.g., double or multiple negation, or nonuse of the third singular verb ending *-s*) was in fact a systematic difference between dialects, subject to internally governed rules. He emphasized that the BEV system was not completely different from that of other English dialects: in fact, it shared a great majority of rules with them. Within that overall similarity, however, were subsets of rules which might not be easily integrated into other English grammars. These may even be located at strategic points, close to the grammatical core of the dialect.

This section will first examine Labov's approach to the syntax of double and multiple negation in BEV and other dialects. Prescriptivists took the view that the dialect-speaking child who produces *She don't know nothing* is trying to say *She knows nothing*, but has unwittingly used an extra negative and so conveys the opposite meaning. Labov stressed that this was a false interpretation: a BEV speaker, like standard American English speakers, is capable of distinguishing between ordinary negation and emphatic negation. The means of doing so are different in each dialect. (In emphatic negation, where two negatives result in a positive, BEV uses stress on both negatives. Such stress is lacking in ordinary negation where two or more negatives yield a negative.) The two dialects differ thus:

	White dialect	BEV
Positive:	He knows something	He know something
Negative:	He doesn't know anything	He don't know nothing
Double neg:	He doesn't know *nothing*	He *don't* know *nothing*.

The main rules for negation can be summarized as follows:

(a) In all dialects, the negative is attracted to a lone indefinite before the verb (e.g., *Nobody knows anything*, rather than **Anybody doesn't know anything*).

(b) In some white dialects, the negative may also combine with other indefinites (e.g., *Nobody knows nothing*; *He never took none of them*).

(c) In other white dialects, the negative combines with all indefinites and occurs in preverbal position in the same clause (e.g., *Nobody doesn't know nothing*).

(d) In BEV, negative concord is obligatory in all indefinites within the clause, and may even occur in preverbal position in following clauses (e.g., *It ain't no cat can't get into no coop*,

equivalent to standard English 'There isn't any cat that can get into any coop').

From the point of view of language variation and logic, two important generalizations can be made. First, all dialects share a categorical rule which attracts the negative to an indefinite subject. Second, dialects differ mainly in the extent to which the negative particle is also distributed to other indefinites and to preverbal position in the main and subordinate clauses. Some important parallels arise between this study and those of phonetic variables: (a) the syntax of negation shows the effect of linguistic conditioning—certain environments enhance it, others do not; (b) negation is subject to variation according to social group (in this case, at least with respect to ethnicity); and (c) style is a factor which should enter into consideration—for example, in the choice between single versus double negation in certain dialects, or negation across clauses in BEV.

Another example within BEV syntax which might easily be misconstrued as logically inferior to the standard pattern concerns the deletion of the copula (essentially the verb *be* before an adjective, preposition, or noun phrase; for example, *He is tall*, although some researchers, including Labov, include auxiliary *be* as in *She is playing* in their analyses). This area of syntax will be discussed in some detail, not so much to iterate Labov's position in the difference–deficit debate, but to show the interplay between phonology and syntax and the development of the concept of variable rules.

BEV frequently shows the absence of *be* in a range of syntactic environments (another construction showing the presence of invariant, habitual *be* in BEV and other dialects, will not be examined):

NP:	She ϕ the first one started us off.
Predicate adj:	He ϕ fast in everything he do.
Locative:	You ϕ out the tape.
Negative:	But everybody ϕ not black.
Participle:	He just feel like he ϕ getting cripple up from arthritis.

In attempting to establish whether this phenomenon is rule-governed, it is important to check whether there are any contexts in which copula deletion is *not* permissible. Among these is the past tense, which always requires *was*. Other environments which frequently, if not mandatorily, require some form of the copula are the first person form *I'm*; the form *ain't*; interrogative questions (*Is he dead?*, not **He dead?*); tag questions (*Is that a shock or is it not?*); and infinitives (*You got to be good*, not **You got to good*). *Is* ([z̧]) and *are* ([ə] or [ər]) are deleted, but not *am* ([m̧]). Since there are general phonological processes deleting certain sounds in unstressed syllables (notably [r], [ə], and [z]—but not [m]), Labov sought to account for copula

383

deletion in BEV in terms of an interplay between these processes and syntactic environments, rather than as a purely syntactic process. The most inspired part of the analysis was a careful comparison between contexts in which standard American English (SAE) frequently contracted the copula, and in contexts in which it did not. Labov pointed out that wherever SAE permits contraction, BEV permits deletion:

SAE	BEV
She's the first	She φ the first
He's fast	He φ fast
You're out of the tape	You φ out the tape

More significantly, the contexts in which SAE disallows contraction are precisely those in which deletion is ruled out in BEV (zero denotes a deleted copula):

	SAE	BEV
(a)	*Sentence-final position*	
	*He's as nice as he says he's.	*He's as nice as he says he φ.
	*How beautiful you're!	*How beautiful you φ!
	Are you going? *Yes I'm.	Are you going? *Yes I φ.
(b)	*An unstressed following word*	
	*Who's it?	*Who φ it?
	*What's it?	*What φ it?
(c)	*Ellipsed elements*	
	Is he running? *He's—now.	Is he running? *He φ—now.

The isomorphism between the two dialects with respect to the contexts of contraction and deletion suggests that they are governed by the same logic. From a detailed examination of general phonological rules like glide deletion, [r] deletion, and consonant-cluster reduction, Labov concluded that the correct analysis of the copula was one which posited a general contraction rule on a common underlying form for both dialects, followed by a deletion rule in BEV. He did so using the techniques of (early) generative grammar and quantitative analysis of variation. At the same time, he claimed to have widened the concept of 'rule of grammar.'

6. Variable Rules

Variable rules were first introduced in Labov's analysis of the BEV copula in 1969. They are based on the model of rules in generative phonology, but are adapted to account for variation. Rules in generative phonology are either optional or obligatory. A simplified version of a generative rule for the deletion of [t] or [d] at the end of words in English could be written:

$$t, d \rightarrow \phi / [+ \text{cons}] \text{—} \#\#[-\text{syll}] \quad (\text{optional})$$

Informally, this says that a word-final [t] or [d] is deleted after a consonant if the following word does not begin with a vowel, and that the rule is an optional one (key: → = 'becomes'; φ= 'zero';/= 'in the following environment'; [+cons]—= 'after a consonant';— ## = 'before a word boundary'; [−syll]= 'nonsyllabic element').

Labov noted that, in a large corpus, the frequency of application of an optional rule might depend to a large extent on particular aspects of the linguistic context. Two or more contexts which satisfy the structural description of such a rule might not have the same effect—one may favor application 90 percent of the time, the other 15 percent of the time. Variable rules are an attempt to incorporate such tendencies into the formal statement of a rule. They differ from the rules of generative phonology in two respects: they include social factors as a possible constraining environment; and they specify the likelihood of a rule applying in a particular environment on the basis of social and linguistic constraints. The following variable rule version of t/d deletion contains the further specification that [t] and [d] are more likely to be deleted when they are not part of the past-tense morpheme:

$$t, d \rightarrow \langle \phi \rangle / [+ \text{cons}]^\beta \langle -\# \rangle \text{—} \#\#^\alpha \langle -\text{syll} \rangle$$

The angled brackets are used to signify variability: [t] and [d] are variably deleted; and $\langle -\# \rangle$ (i.e., the lack of a morpheme boundary) and $\langle -\text{syll} \rangle$ are variable constraints. The absence of angled brackets around [+cons] and ## implies that these are obligatory environments for the rule. The Greek letters suggest a weighting of the optional constraints: α is a more significant constraint than β, and so on. That is, the phonological constraint of a following consonant is weighted more heavily than the grammatical constraint of t/d not being part of the past-tense ending. The rule thus informally states that word-final [t] or [d] is variably deleted after a consonant, more often if it is not a separate grammatical morpheme, and even more often if it is not followed by a vowel.

It is also possible to add social factors to create a combined sociolinguistic environment. Thus, features like [+ middle class], [+ female], etc. might be considered to have a constraining effect parallel to that of the linguistic environment. In the original variable-rule proposal, social factors were placed outside the system of variable linguistic constraints to predict relative frequencies of occurrence.

The variable rule was further developed in the work of Cedergren and Sankoff (1974), who devised a system of assigning probabilities (weightings) to each of the constraints by a procedure known as 'maximum likelihood.' The analysis is performed using as input the data on rule applications in various environments. The method of calculation assumes that the constraints are independent of each other for their effects. The computer program that they

developed for the analysis, called VARBRUL, has since been considerably revised and updated by Sankoff and Rousseau (see *Statistics in Sociolinguistics*). In VARBRUL analysis, the constraints (or 'factors') are arranged into factor groups. For the t/d deletion rule, the factor groups would include [+ #], [− #] (i.e., whether t/d belonged to a grammatical morpheme or not); [+ syll], [− syll], and φ (i.e., whether t/d was followed by a word with an initial consonant or vowel, or was sentence-final); plus the various social groups judged to be relevant to the analysis (e.g., [UMC], [LMC], [WC], etc.; [+ female], [− female]). The elements in a factor group are in complementary distribution: they exhaust the group without overlapping with each other. VARBRUL generates two important analyses for the sociolinguist. One is a probability or weighting associated with each of the factors, ranging from 0 to 1. A factor that receives a weighting greater than 0.5 favors the rule; a value less than 0.5 disfavors it. A factor value of 1.0 does not imply 100 percent application when that factor is present in the rule environment—rather, it signifies that the factor favors application more than any other in its group. The second analysis generated by VARBRUL is an input weighting (or input probability) which reflects the propensity of the rule to apply on its own, apart from the influence of the environment.

Labov insisted that he was not merely writing up statistical statements or approximations to some ideal grammar, but that he was setting up a set of quantitative relations which are the form of the grammar itself. This has been the subject of much criticism, notably on the grounds that variable rules conflict too much in intent with the rules of generative phonology to be accommodated in the latter system. Variable rules are located in language use, and—in Chomsky's terms—form part of performance, rather than the competence characteristic of the initial language state. (On the other hand, Chomsky's ideal grammar is unable to deal adequately with language change and, especially, variation.) The real issue, then, is the psychological status of the variable rule: whether human languages are structured around variable rules which include probability statements regarding application, or whether these are convenient descriptions of language use. The criticism has been raised that children cannot have access to information regarding large and varied samples summarized in variable rules.

In a study concerning the acquisition of rules governing the alternation between /-ing/ and /-in/ and the deletion of /t/ and /d/ at the end of words, Labov (1989) argued that the child is in some ways a perfect historian of a language. The acquisition of centuries-old variable rules like these by children between the ages of four and nine precedes the acquisition of many other features of grammar.

Children first show social and stylistic constraints on variation, and later the language-specific grammatical and articulatory constraints. (Social and stylistic constraints in this case concern narrative versus other styles and peer-group versus parents' speech; grammatical constraints on t/d concern whether or not they are part of a morpheme like the past-tense ending or the negative *n't*; and articulatory constraints involve the presence of consonant clusters.) Labov concludes that there is little evidence to support the notion of a language-learning faculty isolated from social and historical development. Children appear to focus on the pattern of social and stylistic variation and to reproduce the historically variable patterns.

Nevertheless, the variable rule is no longer widely used in sociolinguistic descriptions. For one thing, the rules of phonology that variable rules were designed to be hooked onto are not as prominent as they were in the early days of generative grammar. VARBRUL continues to be used as a valuable statistical means of analyzing large bodies of data; and it is usual for scholars to list input probabilities and factor weightings for salient sociolinguistic processes, without attempting to write a formal variable rule.

7. The Syntactic Variable

The linguistic variables studied in sociolinguistics are often phonological ones. Such items are favored because they are of high frequency, are relatively immune from conscious suppression in an interview, and can be easily quantified. But these are not the only units subject to social variation and evaluation. The quantitative study of larger units has been successful mainly at the morphological level (e.g., studies of the choice between the complementizer *que* or a zero morph in Montréal French). Attempts to analyze syntactic choices within the same framework have been less successful. Weiner and Labov's (1983) study of the English passive in sociolinguistic perspective involved treating the active and passive variants of a sentence as truth-conditionally equivalent and as referring to the same state of affairs—that is, as potential variants of a variable. As many critics have pointed out, this analysis is far removed from the earlier phonological studies, since the potential syntactic variables can hardly be said to be semantically neutral or functionally equivalent in the way that phonological variants are. Differences between the active and passive sentences stem from the way in which information is presented in a stretch of discourse.

Another problem in attempting a sociolinguistic syntax concerns what Labov termed 'closing the set of variants'—or noting not only each instance of a particular variant, but also the number of instances when it might have occurred but did not. In the case

385

of relative clauses, for example, it is not possible to contrast occurrences with nonoccurrences, for there are no means of establishing conclusively within a stretch of discourse all the alternate ways of presenting information specifiable by relative clause structures. Although quantitative studies of syntax are on the increase, they generally do not take the linguistic-variable route (see *Syntactic Change*).

8. Refinements, Criticisms, and Pseudocriticisms

The Labovian framework has been successfully adapted by other scholars to the study of language variation in diverse settings. Some refinements of the generalizations based on North American studies have been inevitable. In terms of methodology, individual researchers have had to tailor aspects of the interview format to suit their particular situation. Residents of Norwich, England, lead less stressful lives than New Yorkers and have little to say about personal brushes with death. On the other hand, Belfasters tend to underplay the topic, since it is a fact of daily life. In some communities, women may not be allowed to speak to strange male interviewers. The tests of style-shifting based on reading passages and minimal pairs presume a literate community, and may be unduly stressful to interviewees in a barely literate one. (One way of getting around this problem might be to focus on the recitation of rituals and prayers in eliciting formal styles.)

It has been suggested that it is confusing to the interviewee's expectations *not* to be put in a subordinate position as the one facing the questions in the interview. This criticism misses the point that the good interviewer *does* come with a carefully planned list of questions, but does not let any opportunity slip for digressions and discussions initiated by the interviewee. Most interviews in the variationist tradition have rightly approximated a social visit with chit-chat, rather than an interrogation session.

More significantly, notions like prestige, gender roles in language change, and style-shifting have been modified by closer scrutiny since Labov's early discussions. A striking finding concerning prestige comes from Trudgill's (1983) study of vowel variants in Norwich, in the lexical sets *NOSE, ROAD, MOAN* (ranging from [ɒu] through [uː] to [ʊ]) and *GATE, FACE, NAME* (ranging from [eɪ] to [æɪ]). As part of the interview, he used a self-evaluation test in which informants were asked how they usually pronounced words like these. In the prototype test in New York, people showed a distinct tendency to claim higher use of the prestige form than was evident in their interview speech. Norwich informants were far more prone to underreport their use of prestige forms in favor of working-class norms. In particular, male informants were much more likely to underreport, female informants to overreport. Although Labov had pointed to the existence of covert prestige in his New York study, he was unable to tap into it in evaluation tests. Trudgill conjectures that the difference in attitudes reflects differences in class-consciousness in the two countries—especially a lack of corporate or militant class-consciousness in the USA and the relative lack of embourgeoisement of the British working class. However, the most compelling factor relating to covert prestige was gender, not social class. Many middle-class males (in contrast to middle-class females) appear to share with working-class males the characteristic that they have not so completely absorbed the dominant mainstream values of their American counterparts.

Trudgill used these insights to explain a seemingly contradictory type of change in progress in Norwich, from [ɑ] or [a] to [ɒ] in the lexical set *TOP, DOG, HOT*. At first sight, these appear to involve a change from a regional to a prestigious RP variant. The contradiction lay in the fact that WC women had higher scores of the nonprestige [ɑ] or [a] than WC men. (For the MC, women had lower scores than men on the nonprestige variant, as expected.) Trudgill shows it to be a two-pronged change in progress: one from above the level of social consciousness, introduced by MC women who have access to RP in a way that WC women do not; the other from below the level of social consciousness, this time by men, who are introducing the low-prestige variant ([ɒ]) from the neighboring counties. Middle-class males follow the lead of working-class males. Thus, it is the working-class women who to any great extent have preserved the unrounded vowel.

It is generally true in all English-speaking communities, Western Europe, and Latin America that for stable sociolinguistic variables women use more prestige variants and fewer stigmatized variants than men. Studies in certain localities in non-Western countries like Kenya, Iran, Jordan, and India suggest the opposite. The reversal of the patterning of prestige variants (as compared to Western findings) seems to appear in all social classes, including those educated women who play a major role in public life. More rural studies from non-Western countries are needed to complete the picture concerning gender-based responses to prestige in language.

Sociolinguists at the beginning of the twenty-first century accept a more general conception of style-shifting than implicit in Labov's early work, based on Bell's (1984) notion of 'audience design' (see *Audience Design*). Bell stressed that stylistic variation was governed not so much by monitoring of one's speech habits (or attention paid to speech), as by a speaker's perception of his or her interlocutor's characteristics. Style is thus a special (and subconscious) 'tailoring' of language to fit the requirements of various types of listener. Although monitoring may be inherent in the

reading style studied by Labov, a more general explanation would link it to the enactment of a role played out in front of a reading audience—that is, to a teacher in a classroom situation. This notion of style fits in with the accommodation theory of language-use stressed by social psychologists (see *Speech Accommodation*). However, it is not easy to operationalize within the constraints of the sociolinguistic interview.

Labov's initial analyses of BEV stressed its overwhelming similarities with other American English dialects, motivated in part by the counterclaims of the deficit school of thought. Much more attention has since been paid to the ongoing divergence between black and white speech (Labov and Harris 1986), as witnessed in innovations like the use of -*s* as the marker of the past in narratives. Even the celebrated analysis of the copula has been modified in ways that stress the difference between BEV and mainstream American English (Baugh 1980). Baugh used an extension of Labov's original database (utilizing the data from the Harlem adolescent groups in full) and an update of the Cedergren and Sankoff (1974) program in his re-examination of the copula in BEV. With the resulting extra tokens, he was able to separate two environments that Labov had conflated out of procedural necessity (the original number of tokens for locative and adjective environments being too small for reliable statistical analysis). Baugh showed that these two environments had a different effect: for locatives, contraction was favored over deletion; for adjectives, the reverse held. Baugh concluded that the phonological and grammatical conditions on the copula contraction/deletion rule operate independently, yet simultaneously. It was more feasible to posit a zero copula in adjectival environments than a contraction rule followed by deletion. The re-analysis thus illuminates a fundamental similarity with Caribbean Creole English varieties, and a significant difference from other American English dialects. While calling into question Labov's synchronic analysis of the BEV copula, Baugh's study validates the broad quantitative framework. (Labov's observation on the relationship between the two dialects can be modified to state that where SAE permits contraction, BEV permits deletion, or—in the case of the locative—a zero copula.)

Appraisals of Labov's approach to social class (see *Social Class*) are widely divergent, even contradictory. One view holds that his work does not deal with social class at all: what he calls social class is actually status, since this is what a socioeconomic index measures. Class is seen as a fundamental cleavage over the means of production and the extraction of surplus profit from labor. This aspect of the class struggle is not consonant with Labov's stress on shared norms and common evaluation in a

stratified model. In fairness to Labov, it must be said that he does show awareness of the class/status distinction in much of his work (see, for example, Labov 1972a: 44–5). Implicit in much of the research on BEV is the idea of dialect conflict, as well as the interplay between class and ethnicity. His later work stresses divergence rather than a common body of shared norms. Critics who advocate the conflict approach to social class have themselves found it an extremely difficult concept to use in variationist analysis. The socioeconomic scales are a practical means of reflecting stratification patterns in a society and its members' subjective perceptions, whatever the deeper causes of such phenomena. Certainly, variationists need to take greater care in motivating some of the categories posited on their socioeconomic scales. Characterizations like 'middle working-class' and 'middle middle-class' need to be clarified in terms of what their typical members in specific communities are, and how they differ from members of adjacent categories.

Another school of thought criticizes Labov for overuse of social class/status, and would prefer to see a focus on individual behavior. An early criticism was that a group analysis might mask the significant behavior of certain individuals—average scores hide the extreme cases. Horvath (1985) has argued against an approach that first puts individuals into social classes and then examines the linguistic behavior of the preconstructed group. In her study of English in Sydney, Horvath first examined the clustering of linguistic variants using a statistical technique known as 'principal components analysis,' and then examined how the intrinsic internal structure corresponded with combinations of social factors. She argues that this procedure reveals certain patterns that are hidden by *a priori* determination of the relevant social groups. In particular, individual speakers are never 'lost,' since individuals are plotted on graphic displays. The claim that individuals are lost in the traditional Labovian analysis seems unwarranted, if one recollects his detailed discussion of the degree of membership in core and outer groups in the Harlem studies. The characterization of 'lames'—people on the fringe of BEV usage, showing some features of the dialect, but generally peripheral to the core group socially and linguistically—is an early forerunner to the kind of approach that Horvath calls for. However, both approaches to the analysis of linguistic behavior have to face the problem of defining social groupings and deciding which individuals fall into which group: cluster analysis of the sort proposed by Horvath seems to postpone it to a later stage. In the same vein, a major objection of the neo-Labovian school spearheaded by Romaine (1982) is that the cities which it has studied fail to show the monotonically increasing patterns of variation found in New York City.

Romaine advocates a breakaway from what she describes as the exclusively status-based theory and straightforward correlational methodology of the Labovian paradigm. The most important work in this vein is that of Milroy (1980) on social networks, and LePage and Tabouret-Keller (1985) on focusing and diffusion. However, the criticism of Labov's work as largely correlational does scant justice to the breadth and subtlety of the work in Martha's Vineyard and New York, on BEV, and the work on Philadelphia vowel systems. The patterning of sociolinguistic variants in New York City does not look nearly so monotonic when Labov's work on gender and ethnicity are taken into account. Any proposal that class structure has nothing to do with linguistic variation and change does not seem very promising.

Macaulay (1988), working within the variationist paradigm, criticizes it for concentrating too much on what is easily quantifiable (e.g., phonological variants) and thereby failing to exhaust the richness of the carefully collected materials (e.g., in discourse strategies and syntactic choices). This criticism cannot be levelled at Labov, who has worked variously at the structure of narratives, ritual insults, broad syntactic structures, pedagogical implications of dialect use, and applications and testing of sociolinguistic theory within the judicial system. More generally, the criticism has been raised that the variationist school stresses statistics and quantification to the detriment of an overarching sociolinguistic theory. It is perhaps true that Labov's sociolinguistic focus seems to be increasingly narrower (as in the fine-grained studies of vowel-shifting in northern US cities) (Labov 1994, 2001, Labov et al. forthcoming). However, scholars with other perspectives (e.g., gender, the political economy of language, and social psychology) are increasingly using variationist findings in their attempts at constructing theories of social behavior.

As Fasold (1985: 552) writes, there is no substitute for human insight to be found in statistical analysis, or in other predetermined organization of raw data. Yet there is little reason to accept the validity claimed by a researcher based only on flashes of insight. Validity in sociolinguistics should be established on the common grounds of objective analysis. If that analysis can be supported by appropriate quantitative techniques, so much the better.

9. Conclusion

A whole school of sociolinguistics has arisen out of Labov's early studies, not entirely in ways that he envisaged. In particular, linguistics and sociolinguistics have not converged in the way that Labov hoped, and sociolinguistic rules describing variation have not been incorporated into nonsociolinguistic theory. With the benefit of hindsight, this state of affairs is not to be lamented. The strengths of sociolinguistic analyses lie not so much in their contributions to a Chomskyan conception of linguistic theory, but more in addressing their own internally generated problems concerning the relatively structured use of variable resources of a language for certain social purposes, as well as their implications for language change.

Sociolinguistics and Language Change
J. Milroy

It may seem surprising to the lay person that orthodox historical linguistics has not taken very much account of social factors in attempting to explain linguistic change. Some experts insist that social factors are of little relevance, and that the causes of change are to be found in phenomena that are more central to language structure, for example, 'natural' phonetic processes (see *Language Change and Language Acquisition*). However, there is one important difficulty, which applies especially to the explanation of *sound* change. This is that if one does not take social factors into account, there appears to be little reason why sound change (and some other kinds of change) should take place at all. If, at some place and time, the sound [a] should change to [o] in all relevant words, the language has not gained anything by the change, as one tiny segment of sound cannot be 'better' or more efficient than another. Indeed, it can be argued that change is dysfunctional, since, when a change is introduced by some section of a speech community, it is in principle possible that the new form will not be immediately understood. However, change is continuously in progress, and its operation has greatly altered the sound systems and structural characteristics of languages in the course of history: Old and Middle English, for example, were clearly very different in pronunciation and grammar from twentieth-century English, and language change can be very rapid.

It seems that the causes of change are not to be found in the structure of languages as such, but in the behavior of speakers. As speakers in social groups manifestly attach great social importance to quite small differences in pronunciation, which are arbitrary in linguistic terms (i.e., one sound is just as good as another), sociolinguists argue that collecting and analyzing the language of live speakers in social groupings can be used to advance the understanding of the causes of linguistic change. The basic problem to be solved is known as the 'actuation problem,' and it can be stated thus:

Why do changes in a structural feature take place in a particular language at a given time, but not in other languages with the same feature, or in the same language at other times?

Thus, one might ask why the French language has lost many final consonants in the course of history, while Spanish and Italian have preserved them, and (at the dialectal level) why some dialects of English have lost final and preconsonantal [r] in words such as *car, card,* while others (for example, Scottish and North American English) have retained it. Although the actuation problem cannot be completely solved, sociolinguists attempt to come closer to understanding it.

Most changes in language, as far as is known, take place without self-conscious attempts being made by speakers to implement them; yet, paradoxically, they must in some way be implemented through speaker activity, as the new forms are accepted and used by new generations of speakers. Self-conscious institutional intervention in language is generally known as 'language planning.' Another phenomenon that may be brought about by institutional intervention is language standardization; from a sociolinguistic point of view, standardization can be seen as an attempt to impose uniformity on a phenomenon which is by nature variable (language), and part of its purpose is to prevent linguistic change. Sociolinguists have up until the time of writing been mainly interested in change that comes about 'naturally,' without conscious intervention.

Three main approaches can be distinguished. The first is associated with the work of anthropological linguists, and focuses on 'language shift'—the replacement of one language by another, perhaps with discernible effects on one or both languages (see *Language Transfer and Substrates*). Work in this tradition traces the replacement patterns as they progress through bilingual populations. It is typically found that some social groups (e.g., females as against males, or a particular social class) lead in the shift, and that the recessive language is replaced by the incoming language in different social situations at different rates: for example, the recessive language normally persists in domestic environments after it has been replaced in most other functions. The study of recessive languages in these situations is referred to as the study of 'language

death.' Typically, these languages undergo a great deal of internal change during the process.

The second approach to language change focuses on monolingual situations in much greater linguistic detail, and is associated with the name of William Labov. It can be called quantitative social dialectology (see *Sociolinguistic Variation*), as it makes use of quantification to reveal patterns of variation in terms of the social characteristics of the speakers studied—age, sex, and social class, for example. By this means, linguistic changes in progress can be detected and traced in fine detail as they diffuse in an orderly way through populations of speakers. These studies usually focus on quite small communities of speakers, and they have shown that, in order to understand linguistic changes, one must first think of changes as coming about in the speech community rather than in the national language as a whole. That is, changes originate not in 'English,' but in some localized variety of English. From localized situations, they may diffuse much more widely, and these wider patterns of diffusion are also studied.

The third relevant approach concerns Pidgin and Creole languages (see *Pidgins and Creoles: Models*). Like the first approach, this involves contact between languages, except that the replacement of one language (an established native language) is abrupt—it is brought about by upheaval of populations who are then thrown together with strangers in situations where there is no common language. Creoles are normally based on colonial languages such as English or Portuguese, with much reduced syntax. Pidgin and Creole studies have greatly advanced the understanding of universals of language change, particularly syntactic universals.

So far, theoretical advances in traditional historical linguistic concerns have come mainly from work in the second approach above. They have been chiefly concerned with sound change and have borne in mind the traditional neogrammarian axioms, which propose that sound change is phonetically gradual and lexically abrupt. In this view, change is believed to proceed by imperceptible degrees affecting all members of a word-class at the same time (e.g., all words with the vowel [a], as in *bat, bad, hand*, etc.). Many sociolinguistic patterns, however, have proved to be different from this: they are lexically gradual and phonetically abrupt, and sound change is often observed to spread gradually through the relevant lexicon, affecting some words before others. Similarly, phonetic differences are not necessarily imperceptible, but may be quite marked. The relevance of these traditional concerns is a matter of debate; what is certainly clear is that sound change is *socially* gradual. It spreads gradually through populations of speakers.

Influenced by Labov, many attempted accounts of language change have used social class as a background to their arguments (see *Social Class*). Change has been seen as spreading upward and downward from some central point in the social-class hierarchy, and social-class differentiation seems to have been thought of as a cause of change. Sex differentiation in language has also been cited as an equally important variable in linguistic change, as males and females are always found to differ in speech, usually with females using more 'careful' or less 'vernacular' speech than males.

Argumentation based on the idea of varying solidarity within and between communities and operationalized in terms of social network has been used to propose a theory that can account for different language situations—encompassing those studied by the three approaches enumerated above. This suggests that, as close and solidary personal ties in communities result in dialect maintenance and resistance to change, linguistic change is facilitated by the development of large numbers of weak ties (see *Social Networks*). If this model is used in interpretation, it appears to account in a coherent way for situations of different orders of magnitude. It is proposed that:

> Linguistic change is slow to the extent that the relevant populations are well established and bound by strong ties, whereas it is rapid to the extent that weak ties exist in populations.

Although traditional historical linguistics neglected speakers (partly because it did not have access to tape recorders), languages that have no speakers do not change. A theory of change must therefore have a place for speakers, and it has been proposed that a distinction should be drawn between innovations and changes in language. An innovation is an act of the speaker, which may or may not lead to a *change*, which is something that is embedded in the language system. In order to make progress here, one must attempt to understand the way in which some innovations in some circumstances can become changes, whereas others fall away without trace. Although the actuation problem is still a very long way from being solved, it is to be hoped that the typical sociolinguistic focus on speaker behavior will make further contributions to linguists' understanding of the nature of linguistic change.

Sociophonetics

S. Wright. Revised by C. M. Sangster

Sociophonetics involves the study of speech in its social context, combing the techniques of sociolinguistics and experimental phonetics, particularly acoustic and/or articulatory analysis. The aim of this approach is to discover the influences of social, situational, and phonetic factors on the articulatory processes which, taken together, amount to 'pronunciation.' Although the term has generally been used to refer only to sociolinguistic research using instrumentally acquired or acoustically analysed data, it can also refer to quantitative phonetic work based solely on auditory analysis. Sociophonetics is the work of phoneticians in the field of variationist or quantitative sociolinguistics (Foulkes and Docherty 1999 propose the term 'accent studies' as an alternative). This article will sketch the field's background in sociolinguistics, describe the nature of the linguistic variables examined, introduce some techniques from experimental phonetics, and then report some results of recent sociophonetics research (see *Sociolinguistic Variation; Dialect and Dialectology*).

1. Background in Sociolinguistics

The principal methodological antecedents of sociophonetics lie in large-scale sociolinguistic investigations of urban societies in the USA (Labov 1966, 1972) and Britain (Trudgill 1974). Projects investigating the social motivation of sound change (see *Sound Change*) in Philadelphia, USA, made extensive use of instrumental phonetic techniques and analysis using acoustic as well as auditory methods. Labov employed instrumental techniques, analyzing spectrographic recordings of the speech of his informants in order to measure vowel quality differences. The acoustic specification of vowel quality for each informant was matched with his or her social profile. This social profile included information about the following social variables: age, sex, social class, social mobility, ethnicity, neighborhood, communication patterns, and knowledge of other languages. The resulting equations enabled researchers to gain a picture of the range of variation in pronunciation likely to exist in any one section of the speech community, and to indicate the nature of the differences between sections of the

community. The analysis of the resulting categories pairing vowel measurement and social groups yielded the basis for an interpretation of changes in vowel pronunciation in the Philadelphia speech community. Labov concluded that the social factors most salient for the variation and changes in progress in the Philadelphia speech community included ethnic diversity and neighborhood or locality, while socioeconomic class (see *Social Class*) was not a significant factor.

In this research, instrumental phonetic techniques, such as the spectrographic analysis of vowel sounds, were used as supplementary, interpretative aids in the examination of linguistic variation and change in its social context. Other early explorations of the combination of sociolinguistic and phonetic techniques are represented by the work of Dressler and Wodak (1982) and Kerswill (1987). It should be noted, however, that although such analysis of vowel differences using F1-F2 plots became quite widespread in sociophonetic work, they have been criticised for not revealing information about lip-rounding, duration or the third formant, and for problems normalising the data; and they are by no means the only acoustic analysis possible. For example, Docherty and Foulkes (1999) and Sangster (2001) report acoustic analyses of variation in closure and friction in the consonant /t/ in two British urban accents, while Yaeger-Dror (1997) and Grabe et al (2000) have used fundamental frequency analysis to explore variation in pitch and intonation.

2. Techniques

Standard techniques in laboratory phonetics include experiments with a relatively small number of speakers and multiple repetitions, but the value of combining the rigour of quantifiable experimental techniques with the use of sociolinguistically structured groups of subjects is increasingly being recognised (Scobbie et al 2000). Experimental phonetic techniques generally control more closely for variability owing to phonotatic effects and speech rate than sociolinguistic interviews intended only for auditory analysis. Recording quality has to be particularly 'clean' if acoustic analysis is to be carried out on interview recordings.

391

2.1 Sociolinguistic Interviews

In a sociolinguistic interview, there may be recordings of the reading of a constructed narrative passage in 'formal' and 'colloquial' styles; of wordlists, and of natural speech, for example, open-ended conversation with a researcher or a co-interviewee (see *Field Methods in Modern Dialect and Variation Studies*). If interviews are not conducted one-to-one but with pairs or groups of informants, collaborative talk about tasks such as amp tasks may also be recorded. A range of recordings from several speakers provides a large corpus of speech suitable for auditory and acoustic analysis of selected variables and allows an expanded analysis of particular variables.

2.2 Acoustic Analysis

Recordings of informants' speech are transferred to a computer for spectrographic analysis, where amplitude and frequency of the signal are plotted along a timeline. Durations of periods of closure or friction can be measured, or analysis of formant frequencies for vowels and sonorants can be carried out. Line spectra for single instances can be generated, and other elements of the acoustic signal, such as voicing and fundamental frequency, can also be analysed (Johnson 1997).

2.3 Instrumental Analysis

Various pieces of laboratory equipment are used to gain an insight into some particular aspect of the speech process, usually simultaneously with an audio recording. These approaches can include the following: imaging techniques such as ultrasound or fMRI to examine the motion of the tongue and other organs of speech; airflow measurement with a face mask or plethysmograph; electromagnetic midsagittal articulometry (EMMA) to track the motions of the articulators in relation to one another; or the use of low electrical currents to measure rapid changes in the state of the vocal folds (electroglottography), in the muscles involved in speech (electromyography) or contact of the tongue on the palate (electropalatography). See below for more details on electropalatography, the technique used in the experiments discussed in Sect. 3 below; otherwise see, e.g., Stone 1996 for more details about these speech physiology instrumental techniques.

2.3.1 Electropalatography

Parallel audio and electropalatographic recordings provide a limited visual analog of (palatal) articulatory gestures for each speaker in the sociolinguistic sample. These data allow the detailed articulatory analysis of variables that may be noted in conversational recordings, and provides a basis for the development and selection of materials for use in controlled listening experiments. The technique is used to obtain data on the exact location and timing of tongue contacts with the palate during continuous speech (Hardcastle et al. 1989). A subject wears a moulded acrylic artificial palate which is embedded with electrodes. When the tongue touches one of these, an electrical circuit is completed, and the resulting signal from that electrode is recorded and stored on a computer. The data are subsequently formatted in diagrams modeling the arrangement of electrodes on the palate, with a dot indicating no-tongue contact, and a circle indicating contact for at least a minimal period of that particular scan. A specimen is illustrated in Fig. 1.

2.4 Phonetic Experiments

2.4.1 Production Experiments

These allow the researcher to carry out detailed analysis of selected variables. Experiments involve audio recording, under controlled conditions, of speakers reading texts designed to focus on particular targeted variables. Either the audio recording will be used for acoustic as well as auditory analysis, or an instrumental recording such as an eletropalatographic recording is made simultaneously. Unlike sociolinguistic interviews, the text is precisely controlled, and often repeated several times. Stimuli presentation tools and carrier sentences are commonly used.

2.4.2 Perception Experiments

These are aimed to assess whether listeners are sensitive to particular sociophonetic variables, and if so, whether they consistently use them in making judgments of a sociolinguistic kind. There are different methods for eliciting listener judgments:

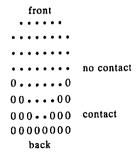
(a) The selection of example of different values of a variable from the corpus of sociolinguistic recording to elicit listener judgments. The problem with this method can be the lack of control over listener-sensitive variables such as


Figure 1. Schematic patatographic printout of a velar closure.

voice quality, speaking rate, and nonidentity of tokens which are different from those targeted.

(b) The use of recordings of constructed parallel texts produced by a single speaker in the sociolinguistic sample (Labov 1972: 146). The problem with this method is the difficulty of controlling the subject's own variation in the articulation of a number of variables in the text.

(c) The matched guise technique, developed by Lambert et al (1960). In this, a speaker able to control more than one accent or register reads a text using different varieties. Using one speaker ensures that listener evaluations are not affected by aspects of personal voice quality. The problem with this technique is that the performer may share and subconsciously encode other cues to the sociolinguistic prejudices being tested.

(d) Informant training. Using listening techniques, and electropalatography as a practical teaching aid to train a subject in the sociolinguistic sample to produce and distinguish different variants of targeted variables as preparation for a sociolinguistic perception experiment. This strategy is an advance on using a trained phonetician in the construction of materials for use in listener experiments.

3. Case-study Illustrating Sociophonetic Methods

One area amenable to study with an explicitly sociophonetic approach involves a set of local, context-sensitive phonetic phenomena called 'connected speech processes' (CSPS), which occur in the stream of everyday speech as a result of a reduction of articulatory effort (Kerswill and Nolan 1989). These natural speech processes may be phonetically motivated (for example, by local phonetic context and speaking rate) but they may also be dialect-specific and socially motivated. Kerswill et al. (1991) conducted a project investigating the social motivation of connected speech processes in the English of Cambridge. Several CSPS which may convey social information about local Cambridge speakers were identified through the auditory analysis of a sociolinguistic survey of Cambridge speech and results of experiments using electropalatography. The socially sensitive features were identified as the processes of /l/- vocalization (where the word *bill* sounds like *biw*), glottalization (where /t/ is realized with a glottal or glottalized stop [ʔ] or [ʔt]), and palatalization (or yod-coalescence, Trudgill 1974) reflected in the representation of the phrase *bet you* as *betcha*. These features carry social information about people and the society to which they belong. Other processes, such as assimilation of adjacent consonants, did not appear to be sensitive to social factors. It was concluded that sociolinguistic CSPS are not influenced by situational features such as style and rates of speaking in the same way that phonetically-conditioned CSPS are.

Kerswill et al. (1991) also investigated the diffusion of sociophonetic features. The diffusion model has been central to the study of linguistic change, from the spread of regional dialect features (Chambers and Trudgill 1988: 182ff), through the postcreole continuum, to language death. According to this model, phonological processes spread through language via linguistic environments and speaking styles. At first, a process is variable and optional in a given environment and style, then it becomes categorical. Finally, the process becomes phonologized. Well-known examples of phonologization are the fronting of velars in Italian and many other languages, and the coalescence of [z] and [j] in English, resulting in the new phoneme /ʒ/. These studies investigate the diffusion of two features in the speech of local Cambridge speakers: /l/-vocalization and yod-coalescence. The focus of the study was the role of social factors such as age, and style of speaking in influencing spread.

3.1 /l/-vocalization

/l/-vocalization is a London dialect feature known to be spreading across south-east England. The spread of vocalization across phonological environments was considered, examining conversational data for older and younger speakers of a particular speech community in South East: local Cambridge English.

Four phonological environments were considered:

1. V–C e.g., *called*,
2. V– #C e.g., *call Susan*,
3. V–V e.g., *believe, calling*
4. V–V e.g., *call Andy*

Southern British English and RP speakers would be expected to produce 'dark /l/' (a velarized or vocalized /l/) in the first two environments. The third was included to facilitate the monitoring of the possible use of nonclear variants (only clear /l/ is expected in this environment), at the same time as serving as a control. The fourth environment was included following informal observation of vocalization in a manner suggesting the spread of the CSP to new environments. The auditory transcription of the data produced a simplified set of auditory categories: 'clear,' 'dark,' and 'vocalized.'

Fig. 2 shows the percentage of the realizations which are vocalized.

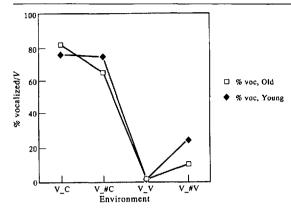
Overall, younger speakers did not appear to vocalize more frequently than other age groups. Although the proportions are roughly similar for each group in the two preconsonantal environments, it is significant that older speakers vocalized word-internally more frequently than before a word


Figure 2. Percentage of vocalization in four environments—conversational data.

demonstrating the essentially sociolinguistic process by which a CSP expands its domain. Kerswill et al. explain the synchronic presence of variation as follows. Although these speakers usually vocalize, their systems coexist in the community with systems without vocalization (fluctuation being expected in any transition stage). Normative pressures against vocalization from prestigious varieties, from norms of correct speech and from spelling, pose difficult choices for these speakers. In the interview situation, the speakers may have been affected by overt social pressures, and may have attempted to avoid the stigmatized vocalized /1/. Since many of them have no dark /1/ in their repertoire, the only alternative is to produce a clear /1/, even in preconsonantal environments.

boundary. This group's behavior suggested that they differentiate between the environments, whereas younger speakers do not.

Two other results suggest a change in progress. First, while the overall rate of vocalization in canonically 'dark' (i.e., preconsonantal) environments was around 75 percent, some subjects produced clear /1/ in this environment. Kerswill et al. considered whether this behavior represents a change in the phonological representation of the words for these speakers, since these subjects were all high vocalizers. The change would be from structure with a lateral consonant in the syllable coda to one with a syllable-nuclear diphthong. Their data supported this interpretation. All speakers categorically used clear /1/ in the V–V environment, but occasionally there was some use of nonclear variants in the V–#V environment. While the older speakers produced 13 percent (3 percent velarized + 10 percent vocalized), younger speakers' use of nonclear variants was much higher, at 31 percent (7 percent verlarized + 24 percent vocalized). The difference between the two age groups was highly significant. It was observed that for some young speakers, words of the relevant structure ended in a diphthong, effectively making it impossible to resyllabify (and 'clarify') a final /1/ before a vowel. They suggest that the presence of a fairly high proportion of dark l's in this context should be interpreted as a sandhi feature, not unlike 'intrusive' /r/ in nonrhotic accents. They concluded that the younger speakers could be beginning to phonologize the l-vocalization CSP.

Second, the fact that the younger speakers did not seem to distinguish between the two preconsonantal environments might indicate that they had generalized the process. By contrast, the older speakers continued to differentiate between the preconsonantal environments to a significant degree. The speech of the young speakers may therefore be construed as

3.2 Yod-coalescence

Yod-coalescence in English is considered to be neither socially stigmatized nor spreading. But this was not always so. It dates back to well before the eighteenth century, when /s/ + /j/ and /z/ + /j/ coalesced as /ʃ/ and the new phoneme /ʒ/ in words such as *nation* and *measure*, respectively (Gimson 1980). In these examples, the CSP was phonologized. By contrast, it has probably never been phonologized across word boundaries, because the coalesced pronunciations of *did you, miss you*, etc., can always be 'unpacked.' Kerswill et al. analyzed three cross-boundary environments: /d/ + /j/, /s/ + /j/ (including /z/ + /j/), and /t/ + /j/. The last environment included a glottal variant, [ʔ]. Fig. 3, below, shows the percentage coalescence for d + j, s/z + j and t + j.

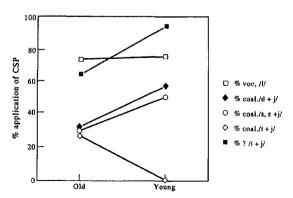
Fig. 3 shows the incidence of l-vocalization and yod-coalescence, and for comparison, the incidence of glottaling. There are two striking features: (a) young speakers have a much higher incidence of coalescence for both d + j and s/z + j than older speakers; (b) they have a much lower incidence for


Figure 3. Percentage of scores for yod-coalescence, t-glottaling and l-vocalization, old and young speakers.

t + j, which seems to be mirrored by a much higher incidence of glottaling. The apparent time increase in yod-coalescence does not, it is argued, indicate linguistic change (the phonologization of yod-coalescence across word boundaries) because there was no evidence that young speakers apply this CSP in a categorical manner. But they did observe that yod-coalescence was phonetically gradual and subject to speaking rate and level of formality.

This observation prompted them to consider the role of style in accounting for the dramatic apparent-time increase in yod-coalescence, since the variable of speaking style may intervene between the linguistic environment affecting a CSP and the CSPS realization.

Thus, they argued that a CSP may be subject to sociolinguistic style, despite the tendency for it to apply more readily at fast speaking rates. They adopted Bell's (1984) concept of sociolinguistic style as 'audience design' (see *Audience Design*): the speaker's total response to the audience—immediate interlocutors, overhearers, and 'referees,' an absent reference group which the speaker wishes to identify with. The possible stylistic influences on the application of yod-coalescence are as follows.

First, the influence of the interview situation itself: young and older speakers could have been reacting differently to the interview situation as a consequence of systematic differences in the relationship between the interviewer and each subject due to the variation in the age difference. Second, social change (e.g., the likelihood that less overtly formal relationships between strangers are becoming the norm) may account for the fact that young speakers treated the interview situation as more informal than did older speakers. Third, older speakers may have a wider range of speech styles at their disposal—or are simply more willing to use them.

The second notable feature of Fig. 3 is the marked apparent-time reduction in yod-coalescence of /t + j/ and the equally marked increase in t-glottaling/ deletion. The results reflect a complementary pattern in the application of these processes. One process 'bleeds' the other; in phonetic terms, if /t/ has been deleted, it can no longer coalesce with the following palatal glide. The converse is not true: there is no reason why /t/ should not be glottalized/deleted after yod-coalescence. The quantitative patterns in their data confirm this view. They argue that if yod-coalescence is assumed to be a unitary process, the coalescence of /t + j/ would be expected to show the same increase as the other two environments. And they suggest that the reason that /t + j/ does not show the same increase is related to the steep apparent increase in glottaling, which prevents coalescence. They conclude that the reason for the apparent-time increase in glottaling is most likely stylistic; specifically, it is a sign of an informal style.

3.3 Comparison of /l/-vocalization and Yod-coalescence

Kerswill et al. discuss the apparent-time increase of l-vocalization and yod-coalescence as the possible outcome of phonetically, phonologically, and sociolinguistically similar factors, and consider whether they reflect different, complex interactions of factors. They observe that l-vocalization is nearing completion in preconsonantal environments, and is spreading prevocalically where there is an intervening word boundary. They also infer that it is heavily implicated in phonological restructuring because of its occurrence prevocalically (outside the traditional domain of 'dark' /l/) and by the sporadic unexpected occurrence of clear /l/ preconsonantally. Finally, it is socially stratified, but not overtly stigmatized. They conclude that the small apparent-time differences do not obviously result from style differences. The younger speakers' greater use of vocalized and dark /l/ before a vowel is the opposite of what might be expected from their more casual speech style. Preconsonantally, there is little difference between older and younger speakers.

Kerswill et al. note that yod-coalescence is the exact converse of l-vocalization in its patterning. They conclude that while it is neither subject to social stratification, nor to change in its linguistic status, it is sensitive to style changes. However, it is sensitive to a combination of interacting stylistic features. Yod-coalescence is directly affected by speaking rate and attention to articulatory clarity in addition to formality of speech situation. It is not a Labovian marker, that is, a variable showing stylistic variation that exactly parallels its stratification, with 'correct' forms occurring in formal styles and in the speech of higher social classes. However, as part of Labov's concept of formality, speaking rate and attention to articulatory clarity do co-vary with it. The likelihood that higher social classes use yod-coalescence less than classes lower in the stratification would imply that the former speak more carefully (a reasonable assumption based on the level of education and concomitant beliefs about 'correct' and 'good' speech). Kerswill et al. argue that its patterning might resemble that of a Labovian marker though for different reasons. For while the relationship between Labov's variables and the social values they encode is essentially arbitrary (for instance, there is nothing about a vowel's height that directly symbolizes 'class'), there is a nonarbitrary relationship for yod-coalescence, since its application is directly relatable to articulatory economy.

4. Future Work

Future work in sociophonetics will focus increasingly on investigating the relationship between sociolinguistic variation and sound change within a speech

community. Acoustic analysis can grant further insight into many areas of sociolinguistic investigation and experimentation, and there are further dimensions of observation offered by instrumental articulatory analysis. The advance of the field will continue to depend on increasingly sophisticated and accessible instrumentation for analyzing natural speech in its social context. As the technology improves, and as sociolinguists realise the value of precisely-controlled phonetic experimentation while phoneticians recognise the significance of sociolinguistic factors, the field of sociophonetics will continue to grow.

Sound Change

J. J. Ohala

Sound change refers to changes in pronunciation of words or morphemes over time when these changes seem to be attributable to phonetic and phonological causes, not morphological, semantic, or cultural. Pronunciation changes due to the latter factors have other designations, for example, analogical leveling, expressive change due to sound symbolism, spelling pronunciation, and so on.

Introduction

Sound change manifests itself in many ways. When reading older literature one becomes aware that certain words are used in rhymes which do not rhyme in twentieth-century pronunciation, as, for example, in the following lines from Chaucer's *Knight's Tale*:

But mercy, lady bright, that knowest weel [= 'well']
My thought, and seest what harmes that I feel.

The vowels in these words 'well' and 'feel,' which are [ɛ] and [i], were both [e:] in Chaucer's speech.

Regional dialectal differences must be due to sound change if it is allowed that the same word must have had a uniform pronunciation at some point in the past, for example, presence versus absence of postvocalic *r*s in American versus British English: 'beer' is [biɹ] in the USA but [biə] in British Received Pronunciation; similarly, [tʃɛɹ] and [tʃe:ə], respectively (see *Dialect and Dialectology*).

On a much broader scale of 'dialect' differences, an examination of the pronunciation of cognate words

in related languages also suggests the action of sound change:

English	Italian	(1)
foot [fʊt]	piede [piɛde]	
fish [fɪʃ]	pesce [peʃːe]	
flat [flæt]	piatto [pjatːo]	

Within a given language, morphemes that have a different pronunciation in different morphological contexts (e.g., due to the addition of affixes) give evidence of sound change that occurred in one morphological environment and not another, for example,:

extreme [ɪkˈstɹĩm]	extremity [ɪkˈstɹɛ̃mɪti]	(2)
repose [ɹɪˈpʰouz]	repository [ɹɪˈpʰazɪtɔɹi]	
act [ækt]	actual [ˈækʃuəl]	

Such changes are said to exhibit 'morphophonemic alternations.'

Finally, some cases of contextually determined variation in the phonetic form of a given phoneme may be a manifestation of sound change, for example, the phoneme /t/ may be realized as [tʰ] or as [ʔ] in some American dialects:

Trenton/ˈtɹɛntən/
[tʰɹɛ̃tʰn̩]~[tʰɹɛ̃ ʔn̩] (3)

1. The Importance of Sound Change

A systematic analysis of such evidence of sound change and other forms of language stimulated the development of linguistic science at the beginning of the nineteenth century and led to the development of the comparative method which permitted the reconstruction of languages past. On the assumption that sound change must be happening in the twentieth century as it has in the past, researchers in language acquisition have been motivated to examine the errors of first and second language learners in order to discern possible parallels between variation that is diachronic (across time) and synchronic (at one point in time) (see *Language Change and Language Acquisition*).

Physiologists often gain valuable insights into the workings of the healthy body by studying the diseased body. Parallel to this strategy, many researchers regard sound change as a failure of speech communication, that is, a failure to convey a pronunciation norm, and examine it for hints on how speech production and perception—both their physiological and the cognitive aspects—work normally and successfully.

2. The Literature on Sound Change

The documentation of sound change is enormous and represents one of the great scientific treasures of linguistics. From comparative grammars of language families as well as the vast literature giving descriptions of the phonemic and morphophonemic systems of single languages it is possible to extract much valuable information on sound change. Unfortunately the digging is hard in this quarry because there is no standardization of terminology or phonological symbols and the methods of presenting the data vary widely. A few of the more common forms of sound change are reviewed here with examples of each.

2.1 Assimilation

This is a change of a speech sound so that it becomes more similar or identical to another adjacent sound:

'contend' is derived from the original Latin morphemes   (4a)
com + *tendere* 'with' + 'stretch, strain'; the final *m* of *com*
became *n* by assimilating to the place of the following *t*.
Italian *notte* comes from the Latin stem *noct-* 'night'; here   (4b)
the *c* (= k) assimilated completely to the following *t*.

The overwhelming majority of sound changes are assimilations.

2.2 Dissimilation

This is a change of a speech sound so that it becomes less like another sound in its vicinity or even disappears entirely, for example, 'pilgrim' comes ultimately from the Latin *peregrīnus* 'foreign' (from which the English 'peregrination' is derived). At some time in its history one of the two original *r*'s dissimilated and became *l*. A similar dissimilation relates 'colonel' to original *colonnello* 'column (of soldiers)'; though still spelled with two *l*s, it is pronounced with only one still intact.

2.3 Loss of a Sound

This may occur by 'syncope,' 'apocope,' and so on, depending on where in the word the loss occurs; for example, English 'every' is often pronounced as [ˈɛvɹi], without the medial vowel.

2.4 Epenthesis

Epenthesis is the insertion of a sound in the middle of a word, for example, 'arithmetic' is occasionally pronounced with the medial [-θm-] cluster broken up by an inserted schwa [ə]. Some commonly cited cases of epenthesis, for example, the introduced [p] in '*warmth*' [wɔ̃ɹmpθ], are best considered cases of assimilation: the [p] is the result of the latter portion of the [m] assimilating to the voicelessness and the elevated velum of the following [θ].

2.5 Haplology

This is the loss of one of two successive sounds or sound sequences that are the same or identical, for example, Latin *nutrix* 'nurse' derives from the stem *nutri-* plus the feminine agentive suffix *-trix*, that is, *nutri* + *trix*. One of the two successive identical syllables *tri* was lost. In English the term 'mineralogy' from 'mineral' + *ology* shows haplology with respect to two original successive syllables that were similar but not identical.

2.6 Metathesis

This is the transposition of two adjacent sounds. In Old English the source of the word 'wasp' had two varying forms, *wæsp* and *wæps* (as did its Indo–European source **wopsā* and **wospā*). Similarly, Old English showed variant forms *āscian* and *ācsian* for 'ask.' In some nonstandard dialects of American English this word may be pronounced [æks].

3. The Process of Sound Change

Among those who study sound change some of the greatest controversies arise over how and why sound change takes place. In fact these disputes have been raging for well over a century since approximately the neogrammarian revolution in the mid 1870s. No discernible consensus has been reached yet. This short article attempts to convey some of the origins of these disputes and their parameters.

Although speculation about sound change can be found as early as Plato's *Cratylus* and was very common throughout the eighteenth century, it was not until the pioneering work of philologists such as Samuel Gyarmathi, Rasmus Rask, and Jakob Grimm, that a rigorous, systematic study of sound correspondences between cognate words of different languages was undertaken. What has come to be known as Grimm's Law (Grimm 1822), but was first proposed by Rasmus Rask in 1818; documented a fairly regular (but not exceptionless) correspondence between Greek voiceless stops and Germanic voiceless fricatives: Greek p, t, k = Germanic f, þ(=[θ]), h (=[x]); Greek voiceless aspirates and Germanic voiced stops, ph, th, kh = b, d, g; Greek voiced stops and Germanic voiceless stops, b, d, g = p, t, k. Some examples are given in Table 1.

Two fundamental assumptions about sound change started the controversy. The first is the fairly commonplace observation that sound change seems not to happen all of a sudden. There has never been a report in history that, 'Today on November 23, 1753, we all ceased pronouncing nasal consonants after vowels and instead made the vowel distinctively nasal.' This leads to the belief that sound change occurs so gradually as to be virtually undetectable.

The second belief arose when Hermann Grassmann and Karl Verner discovered in the 1860s and 1870s rules for two major classes of exceptions to Grimm's Law. The impact of this achievement on the philological community of the time cannot be overestimated: for more than four decades philology had accepted, with Grimm, that sound change, whatever its causes, showed the same messiness in application as other aspects of human behavior: there were generalizations to be made but there were inevitably exceptions to these general statements. When Grassmann and Verner showed that even the exceptions (at least a major part of them) could be accounted for by a general rule, they came to believe that sound change operated mechanically and without exception (unless dialect borrowing and analogy interfered with the regular pattern).

As a consequence of sound change applying mechanically and without exception—that is, that all eligible words were affected by it—it was supposed that sound change must progress in a phonetically gradual way. In opposition to the neogrammarians and their view that sound change applied mechanically and without exception were the traditional philologists who insisted that 'each word has its own history' (and thus defies a rule-based account).

The neogrammarians were aware of certain exceptions to the sound changes they discovered but usually attributed them to psychological and cultural factors (analogy and borrowing from other dialects) which they acknowledged could override the forces that propelled these phonological changes.

In the twentieth century, many linguists, the intellectual descendants of the neogrammarians, acknowledge that sound change does not apply without exception, but they still adhere to the notion that it is phonetically gradual and suppose that, for example, the change of the original Indo–European voiceless stops (preserved in classical Greek) changed to the Germanic voiceless fricatives through a process of gradual weakening of the stop closure. (Even if adherence to the doctrine of the exceptionless of sound change has lessened, virtually everyone agrees that the concept was useful heuristically and had a profound effect on the development of linguistics as a rigorous discipline.) On the other hand there is a renewed acceptance of the traditional philological notion that some or all of the gradualness of sound change—which makes it imperceptible—comes about because a given sound change moves gradually through the lexicon affecting first a few words, then more, and then, possibly, most or all eligible words. This is known as 'lexical diffusion' (Wang 1977). Furthermore, a sound change can create

Table 1. Examples of sound correspondences between Greek and the ancient Germanic languages as covered by Grimm's Law (relevant correspondences are highlighted in bold).

Greek	Germanic	English
po**ù**s, po**d**ós	**f**ôtus (Gothic)	foot
grá**ph**ein	**g**raban (Gothic)	dig, cut (engrave)
to	**þ**at (Gothic)	that
o**d**oús, o**d**óntos	tun**þ**us (Gothic)	tooth
thugátēr	**d**aúhtar (Gothic)	daughter
kánnabis	**h**enpr (Old Norse)	hemp, cannabis
génus	**k**inn (Old Norse)	beget, family, kin
kholé	**g**all (Old Norse)	bile, gall

pronunciation variants which connote social class membership, such that two or more alternate pronunciations are available to a speaker, for example, 'floor' as [flɔ] or [flɔɹ]. Speakers might then fluctuate between one form and another depending on what sort of social impression they would like to convey. A change in social valence of one variant could allow it to spread gradually at the expense of the other (Labov 1972). In a pivotal work, Weinreich et al (1968) advocated, among other things, that a strict distinction be made between how a new pronunciation norm starts vs. how it spreads (from word to word, from speaker to speaker, from one socially marked style of speech to another). Some of the imperceptible gradualness, then, could be in the latter domain. (See also *Weinreich, Uriel*; *Labov, William*.)

4. The Occurrence of Sound Change

4.1 Teleology

There have been many theories regarding why sound change takes place. Among the many early speculations on the matter, now discredited, were that the speech organs evolved to necessitate the change, that migrations to different climates (colder regions, windy regions) caused a change in speaking habits. Among the theories still current in the early 1990s, some important divisions remain. One of these is between those that characterize sound change as teleological or purposeful and those that do not. Another is whether or not it is thought that sound change improves a language in some way. Many purposes have been posited behind phonological change, most of them operating unconsciously. Speakers change their pronunciation, it is claimed, to make the act of speaking easier (i.e., to reduce energy expenditure), to make speech clearer for the hearer, to optimize the structure of the language (the grammar) in a variety of ways, and therefore to make it easier to learn, to process, and to remember.

There is no doubt that speakers do vary the amount of energy they put into speaking; the speech of someone who is tired or ill is often poorly articulated and thus harder to understand. It is also a common observation that speakers may change aspects of their pronunciation in anticipation of the needs of the hearer, for example, hearing-impaired or nonnative listeners, or when the environment or the channel utilized, for example, a telephone line, is noisy. However, it is not clear in such cases whether speakers are introducing a new pronunciation norm as opposed to trying to convey the community norm to the best of their ability. Sound change proper should be limited to cases where there is a change in pronunciation norm.

Among the hundreds of ways that speakers are claimed to change the structure of their language in order to optimize it are the following:

(a) To make the segment inventory more symmetrical, for example, although Old English had voiced and voiceless stops, it had only voiceless fricatives; Middle English added voiced fricatives thus making the voiced/voiceless contrast symmetrical among the obstruents.

(b) On the assumption that there is something unusual or difficult in making syllables terminating in consonants and especially consonant clusters, any simplification of syllable endings is viewed as a move toward optimization, for example, in North American English 'can't' is often pronounced [kʰæt]. Many languages spoken in southeast Asia are known to have undergone remarkable simplifications of the syllable structure such that by the twentieth century some allow only open syllables (those not terminated by a consonant).

(c) Languages are said to eliminate phonological contrasts which serve little communicative function, that is, where they are redundant. Thus it has been observed that of the four nasal vowels of Modern French /ɛ̃œ̃ɑ̃ɔ̃/, /œ̃/ serves to differentiate so few words that it is merging with /ɛ̃/.

(d) To simplify the phonological rules governing morphophonemic alternation, for example, around the ninth century French had a rule distinctively nasalizing just the low vowels before a following nasal in the same syllable; by approximately the thirteenth century this rule had been generalized and thus simplified so that all vowels were nasalized in such an environment.

The problem with analyses such as these and with hundreds of similar ones is that there are so many possible structural features of a language—and occasionally its cultural or political environment—which can be invoked after the fact to 'explain' a given change, that it is often difficult to discern any rigor or discipline in such explanations. It would help if there were statistical studies showing that in an unbiased sample of languages those with a given structural feature underwent a certain type of change at a rate greater than chance—change in a direction judged to represent an optimization.

Structural linguistics introduced a new element into speculations about sound change, namely, the underlying structure of a language, which is often posited to be quite distinct from the patterns and elements directly observable. This underlying structure has been viewed as the relations between phonological elements by the Prague School, where this type of theorizing about language change started around the 1930s, or as rules of grammar by

generative phonology, and its descendants. In fact, so different are the proposals that different generations of structural linguists have made about a language's underlying structure, that there has never been a sufficiently stable and long-lived theoretical base on which to launch extensive and wide-ranging research on sound change.

4.2 Sound Change and Language Improvement

The claim that sound change brings about an improvement to the language in which it occurs is independent of the claim that there is teleology. As with the evolution of species, many might believe that individuals who survive at the expense of others in the face of environmental pressures are in some way better adapted, but they would still not suggest that there was any teleology, any ultimate goal, in determining the direction of evolution. Invoking principles similar to evolution, Lindblom proposes that there are universal 'environmental' pressures helping to shape the sound systems of language and has presented one of the few rigorous statistical studies in support of this: Lindblom and Maddieson (1988) demonstrated that languages utilized simple segment types (e.g., [p, l, j, a]) before utilizing complex segment types (e.g., [tʷ, p' k͡p, ã]). Most languages use exclusively simple segment types.

Some have suggested that there is an inherent teleological element in sound change without t here being any net benefit from such change: language users implementing change for the sake of change—similar to their change in fashions of clothes and automobiles from one year to the next (Postal 1968).

Whatever good does come to a language from sound change it must be localized in time and to a particular domain of language structure because the evidence suggests that there seems to be no net drift of all human languages toward a common sound pattern. The fate of consonant clusters between Sanskrit and Modern Hindi illustrate this. Sanskrit had a fairly rich set of medial consonant clusters; according to some these are relatively complex phonological structures and liable to change. Prakrit which developed from Sanskrit, simplified virtually all of these clusters and changed them to geminates (5):

Sanskrit	Prakrit	English	(5)
ʃuṣka	sukʰːa	dry	
karpūra	kap:ūra	camphor	

However, in Modern Hindi, a descendant of Sanskrit through Prakrit, there are some very common morphological processes which involves deletion of an interconsonantal schwa [ə] thus giving rise to complex clusters again. In some cases the form with a cluster came from concatenated morphemes

that twentieth-century speakers are no longer aware of:

Stem	Suffixed form	English	(6)
nəmək	nəmkin	salt, salty	
kʰəp + ək + i	kʰ·əpti	crazy	

While it is certainly not the norm that phonological processes are eventually undone, there seems to be nothing except chance that would prevent it.

5. Phonetics and Sound Change

Phonetic studies of speech have been applied to issues of sound change for well over a century. Some of the first instrumental phonetic studies were motivated by a desire to explain sound change (e.g., Rousselot's 1891 dissertation). One important finding is common to all these studies: there is a remarkable similarity to the variability found in details of pronunciation—that is, in speech production—by twentieth-century speakers and sound changes that took place in centuries past. Some ventured the opinion that the variation found was ongoing sound change, sound change 'on the hoof,' as it were (see Labov 1981). Some studies have again emphasized the isomorphism between diachronic and synchronic phonetic variation but have taken a different path after that (Ohala 1993).

A great deal of variation is found in speech production, it is noted, but this by itself does not constitute sound change, that is, a change in pronunciation norms, because there is evidence from speech perception studies that listeners are usually able to normalize such variant forms and deduce the norm intended by the speaker. For example, the fricative [s] when produced before a rounded vowel like [u] (as in the name 'Sue' is 'colored' a bit to sound less like [s] in other vocalic environments and more like [ʃ]). This change in [s] is caused inadvertently by the assimilation of the lip shape to that of the following vowel [u]. Nevertheless, listeners have no trouble identifying this variant as the phoneme /s/ as long as they detect the /u/ and can 'blame' it for the distortion. Such perceptual normalization must be similar to those operating in perceptions based on other sensory modalities, for example, vision, where viewers successfully normalize for variations in the size, color, and shape of objects viewed from different distances, different ambient lighting, and different angles. However such phonetically caused perturbations of speech sounds makes speech potentially ambiguous to the listener who has to 'parse' the contextual distortion with the context and not with the given speech segment. Although usually successful in doing this, listeners occasionally fail. In these cases of parsing errors, listeners perceive the contextually changed segment as it is heard, that is, changed, and this becomes the basis for their subsequent changed pronunciations. Further

elaborations of this account of sound change as listeners' parsing errors suggest an explanation for dissimilation.

In contrast to most prior accounts of sound change this one attributes the change to the *listener*, not the speaker. The speaker causes the variation which gives rise to potential ambiguity in the acoustic–auditory signal but this variation only leads to sound change due to the misapprehension by the listener. The error of the listener is unmotivated, probabilistic, and nonteleological, just like inadvertent errors by medieval scribes or modern typists copying manuscripts or students taking lecture notes. The change is phonetically abrupt although its subsequent spread, mediated by nonphonetic factors (psychological mechanisms such as analogy and social mechanisms, as discussed above), could be gradual. A further advantage of this account is that it has demonstrated how certain sound changes can be simulated in the laboratory.

6. Trends in Research on Sound Change

Nineteenth-century linguistics *was* historical linguistics. Synchronic studies existed but were usually not at the center of the linguistic community's attention. In the first quarter of the twentieth century, structural linguistics changed this and synchronic studies dominated. In the 1990s it may be said that, with attention being given to sound change by sociolinguistics, by those in language acquisition, by the phonetic sciences, and in the theoretical domain by generative phonology and its heirs, it is again one of the most active and hotly debated research areas in linguistics.

Subcultures and Countercultures

R. L. Taylor

The terms 'subculture' and 'counterculture' are widely used in sociological research and writing to delineate not only the boundaries around presumed systems of values and norms (i.e., rules and expectations regarding social conduct) that differ from a larger normative system of which they are a part, but to emphasize the diversity of norms and values to be found in heterogeneous societies. These terms are not synonymous, however, but differ in their etiology, in the specificity of their boundaries, and in their relationship to the surrounding or dominant culture. This article deals with the analytical distinction between these constructs (though their empirical manifestations may be mixed), their referents and boundaries, and the processes involved in their genesis, maintenance, and change over time.

1. Subcultures

Although originally employed in the study of juvenile delinquency and criminality, the concept subculture has found much broader application in sociological research—from the study of ethnic, religious, and adolescent peer groups, to the analysis of class and regional differences between population segments within a society (Yinger 1960). In its most common usage, subculture refers to the distinctive norms, values, beliefs, and lifestyles of a group which set it apart from other groups and from the larger cultural and normative system of which it is a part. Though linked to the larger society and culture through a network of social institutions and shared values, a subculture is characterized by a set of 'focal concerns' and a range of components—from the ideational to the physical or material—which differentiate it from

401

the broader culture (Fine and Kleinman 1979). Thus, at one extreme are subcultures sharing few elements of the national culture (e.g., Gypsies), and at the other extreme are subcultures having few truly distinctive elements, but only variant patterns (e.g., regional or class subcultures). Between these extremes are to be found a variety of other subcultures whose members exhibit varying degrees of attachment to the larger society.

Social differentiation in a society encourages the formation of subcultures. The more complex the culture and the more heterogeneous its population, the greater is the number of subcultures. Age, gender, ethnicity, class, religion, place of residence, and region often combine to create a diversity of subcultures in modern, industrialized, and complex societies, all with somewhat differing norms and expectations of conduct. Thus, subcultures tend to overlap one another and the national culture, and individuals may participate in several subcultures simultaneously and to different degrees.

1.1 Subcultural Boundaries

The variety of referents for the term subculture identified above implies that the sharpness of the boundaries dividing one subculture from another is likely to vary, depending upon the focal concerns of the subculture and the degree to which it serves as a major source of identity for its members. Some subcultures are tightly bounded, with well-established interests or concerns which command persistent attention and a high degree of emotional involvement on the part of their members. Others are more loosely focused, with no clearly articulated structure or coherent identity, and only limited agreement on subcultural norms. The boundaries of ethnic subcultures are usually reinforced and sustained through customs, language, and a network of organizations and informal relationships which serve as a source of group identity and solidarity. The boundaries of youth subcultures, on the other hand, are less sharply drawn, though youth in general share certain age-specific focal concerns, ideologies, and styles of behavior that set them apart from children and adults (Hall and Jefferson 1976). For some groups, the boundaries of the subculture may come into focus only on certain occasions, as when their interests or identity are directly threatened. The stigmatizing reactions of the larger society may also serve to sharpen the boundaries of a subculture and set it off against that of the dominant culture. Since the degree of involvement in and attachment to the subculture vary, not all participants are likely to draw its boundaries in the same way.

Although there is no widely accepted procedure for defining the parameters of a subculture, an important part of the process involves a determination of which

aspects of the social life of participants in the subculture are not affected by its norms and values, that is, those domains where the culture rules of the larger normative system prevail, and the extent to which membership in the subculture constitutes a major component of identity (Clark 1974). Thus one can have, at one extreme, membership in an established church or social club requiring a nominal investment of time and affect, and at the other extreme, membership in a religious sect, such as the Amish subsociety in the USA, where norms of behavior as well as economic and social activities are rigidly prescribed.

1.2 Genesis of Subcultures

Several explanations or hypotheses are advanced for the emergence of subcultures. One explanation emphasizes the role of exogenous factors (e.g., immigration) in generating subcultures in societies. Thus contact between groups of different cultural backgrounds brought together in the same society, but prevented through formal or informal means from full assimilation into the national culture, give rise to subcultures based on ethnicity (Yinger 1960). In the USA, for instance, Thernstrom (1980) has identified more than 125 ethnic subcultures derived from the diversity of nationalities that immigrated to that country over the past 200 years, and some 1200 religious subcultures have been identified by Melton (1988). Although members of these ethnic subcultures share many of the cultural elements and norms of the national culture, such values and norms are often blended or refracted through the prism of their particularistic traditions (Gordon 1964).

Subcultures are also seen to arise from differential patterns of interaction or association between individuals who share similar statuses in a society. Segments of the population sharing similar structural positions (e.g., age, gender, class, occupation, etc.) tend to interact more frequently with each other than with individuals belonging to other segments, owing to common problems associated with their status and their relative isolation from individuals occupying different positions. In time, a system of norms, values, and beliefs, i.e., a subculture, emerges, and through interpersonal communication, mass media, and other communication interlocks, may be diffused throughout the social network of individuals who, though widely distributed spatially in society, share a common identification with it (Arnold 1970).

A third hypothesis views subcultures as emerging in response to problems of adjustment, deprivation, or status frustration, created by normative or cultural contradictions in the larger society. This hypothesis, developed as an explanation for juvenile delinquency and other forms of deviant behavior, has been expanded to encompass the study of a wide variety of groups that are marginal to society in one way or

another, and whose lifestyles clash with that of the wider culture. The classic and most influential example of this view remains A. K. Cohen's *Delinquent Boys* (1955), wherein a general theory of subcultures is presented which incorporates the theory of anomie, as developed in the work of R. Merton (1938), in its explanation of the rise and persistence of subcultures. Merton argued that a condition of anomie (i.e., norm conflict) occurs when there are discrepancies or discontinuities between culturally prescribed goals (e.g., higher material achievement) and institutionalized, legitimate means available for achieving them. This situation creates a strain between aspirations and achievement for individuals in certain positions in society whose access to established means are severely limited or denied. In consequence, adherence to prescribed means is weakened or rejected, and various forms of deviance follow. Building on Merton's theory, but adding a psychological dimension to it, Cohen explains the rise of delinquent subcultures among working-class youth as a function of the 'status-frustration' these youths experience in their pursuit of middle-class values and goals, owing to blocked opportunities for success or because of their social inadequacies. The solution to this problem is the delinquent gang or subculture which enables working-class youths not only to strike back at a system that stigmatizes them, but to acquire status on the basis of criteria they can more easily attain. Although some writers object to various aspects of Cohen's conceptualization, most accept his basic argument that subcultures arise in response to persistent structural problems encountered by a sufficient number of individuals who are in effective interaction with each other.

A specifically Marxist interpretation of the rise of subcultures has been advanced by P. Cohen (1972), who emphasizes the relationship between the changing dynamics of class conflict and the emergence of working-class subcultures, together with the symbolic and resistant functions they serve. More specifically, Cohen links the rise of various youth subcultures in England (e.g., the Mods, Teddy Boys, and Skinheads) to changes in the material and social conditions of life in working-class communities, and to historical and economic forces which highlighted certain structural contradictions in the wider society. The tension between the working-class and parent cultures finds symbolic expression in subcultural style, that is, in the argot, dress, music, and rituals of working-class youth which contradict the myth of social cohesion and consensus (see *Social Class*).

Despite differences in theoretical position and/or emphasis, most writers agree that subcultures are likely to arise in societies characterized by social differentiation based on such factors as age, gender, ethnicity, class, or other structural variables, coupled with social, political, and/or economic marginality, which promote differential patterns of interaction and collective identity.

1.3 Subcultural Maintenance and Change

The conditions or circumstances that give rise to a subculture are not necessarily the same as those which sustain or transform it. Structural conditions may change, or the focal concerns of the adherents to a subculture may be redefined or transformed under the weight of new realities, or discovery of alternative solutions to their problems. Much depends on the nature of the subculture and its relationship to the larger society. Its values and norms may inspire a range of community reactions, from bemused indifference, to public anxiety or hysteria, with important consequences for the dynamics of subcultural development and change. A strongly negative community response, involving the media and other agencies of social control, may serve as a catalyst for more intensive subcultural identification and activate a diffusion of its values and norms to a larger segment of the population—a process termed 'deviance amplification' (Wilkins 1965). For example, the negative portrayal of the Punks and Mods in the British press and on television gave instant notoriety to these groups which, in turn, attracted the interest and participation of other youths in these subcultures. On the other hand, the severity of negative public reactions to a subculture may threaten or undermine its continued existence by making it difficult or costly for adherents to participate actively and openly in the group, or by forcing them to seek alternative solutions to their problems. One alternative is to minimize contacts between members of the subculture and the larger society, thereby avoiding public scrutiny and sanctions. Examples include religious and sectarian communes and drug subcultures. In short, negative public reactions may contribute to a sharpening of subcultural definitions and ideology, enlarge the scope of its influence, and promote greater normative isolation and solidarity.

Where community reactions are generally more positive or sympathetic, adherents to a subculture may be allowed considerable freedom to pursue their peculiar values and beliefs without fear of punitive sanctions so long as they do not disturb allegiance to the core values of the larger culture. Indeed, some of the stylistic innovations of a subculture (e.g., dress, music, argot) may be selectively appropriated by some segments of the population, or packaged by entrepreneurs for wider diffusion into mainstream society, and in the process lose much of their distinctive and subversive quality. The conversion of some elements of youth subcultural styles into commodities for mass production (e.g., clothing boutiques, small-scale record shops, etc.) illustrates the process of subcultural

assimilation, as does the incorporation of selected aspects of ethnic traditions into the mainstream of American life.

In sum, the fate of a subculture is much influenced by the nature of public reactions, by the strength of formal and informal sanctions, and by the centrality of subcultural identification for its adherents. Where a subculture is violently repressed by social control agents, it is likely to be driven underground, to develop and refine an ideology of resistence, and to draw its boundaries with greater specificity. Conversely, lacking the means to escape the intrusion of mainstream values or its sanctions, the subculture may be abandoned or driven to extinction. Here, of course, much depends on the centrality of the subculture as a source of personal and collective identity, and the availability of alternative models. Where subcultures are granted some measure of legitimacy or tolerance, they are also subject to change, either because of increasing interaction between those who share the subcultural tradition and those that do not, or because of the assimilating influence inherent in participation in mainstream institutions.

Since each subculture represents a response to a specific set of circumstances, problems, or contradictions, it is ultimately changes in these structural conditions, often impelled by subcultural movements themselves, that induce changes or major transformations in subcultures.

2. Countercultures

Subcultures are only one of several different responses that individuals and groups can make to specific structural conditions or problems they encounter in modern complex societies. The formation of countercultures is another. Following Yinger (1960), who first proposed the term, a counterculture refers to those values and norms of a group that are in sharp conflict with the values and norms of the larger society (see *Antilanguage*). Although countercultures share many of the characteristics of subcultures, they are distinguished from the latter by their inversion of dominant values, and by certain characterological predispositions of their members, including their nonconformist or deviant behavior.

Whereas subcultures seek a 'negotiated version' of the dominant values and institutions in order to preserve the uniqueness of their members' ethnic, religious, occupational, class, or other lines of group identification (Parkin 1971), countercultures attempt to provide alternative values (or to place an exaggerated emphasis on existing ones), around which new identities and norms can be constructed. And whereas subcultures are typically lodged in traditional subcommunities (i.e., ethnic, religious, etc.) of the larger society and evolve slowly over time in response to specific historical and structural

circumstances, countercultures are emergent phenomena, arising from frustrations and conflict-laden situations of more recent origin. Countercultures, like subcultures, are not independent cultures but are characterized by a dialectical relationship to the larger society and cannot be fully understood apart from it.

2.1 Sources of Countercultures

Countercultures are both symptoms of, and solutions to, social dislocations, cultural crisis, and deeply experienced personal frustrations in a society. Although it is possible to distinguish, analytically, between the structural, cultural, and individual sources of countercultures, these sources are highly interdependent and often mixed in their empirical manifestations.

On the structural or macro level, the rise of countercultures is associated with major economic and demographic changes in society which undermine traditional social bonds and statuses and nourish the potential for normative innovations. Rapid economic development, accompanied by affluence, expanding opportunities, and population growth, were all associated with the emergence of countercultures during the neolithic revolution, the eleventh-century industrial revolution, the commercial revolution of the sixteenth century, and the industrial revolution of the nineteenth century (Musgrove 1974). Similar conditions inspired the rise and spread of countercultures among youth in the USA during the 1960s and 1970s. Hence unprecedented economic expansion and related developments are the basic generating forces behind the rise of countercultures in societies, with cultural traditions and historically specific circumstances acting as more precise determinants.

Major economic changes produce social dislocations which upset the balance between norms and values in a society and make the appearance of countercultures more likely. In a rapidly changing and uncertain environment, traditional values become increasingly inadequate as guidelines for behavior and many of the rituals, myths, and symbols of the culture may lose their emotional appeal or meaning. The perceived inadequacies of the prevailing cultural configuration encourage the search for new values and interactional norms, or the inversion of existing ones, as designs for living. This is where countercultures come in. Some seek to reconstruct the social order through radical protest activities or other nonconformist behavior, while others advocate withdrawal from society into separate countercommunities or sectarian groups where new values and norms can be cultivated as paradigms for a new society. Rather than attack the social order to withdraw from it, some countercultures seek simply to facilitate individual ecstasy and

404

self-enlightenment through transcendental experiences (often with the aid of drugs) as a means of discovery of new values and a new way of life.

Certain characterological features or tendencies of individuals also play an important role in the emergence of countercultures. Early experiences of parental rejection, emotional isolation, or other experiences that assault self-confidence and esteem, may predispose some individuals to various forms of negativism, including the adoption of inverted values and oppositional lifestyles, and thus mark them as likely candidates for recruitment to countercultural movements (Yinger 1982). For many such individuals, countercultures offer creative ways of dealing with feelings of personal inadequacy, loneliness, or alienation, while experimenting with alternative values and lifestyles. Positive impulses may also incline some individuals to embrace oppositional values or inverted standards. Individuals whose socialization experiences have enabled them to achieve a high level of moral development whereby self-chosen moral principles guide their behavior, are more likely to be represented among active participants in countercultures than those whose standards of morality are less well developed (Haan et al. 1968). The growth in social inequality, greed, and various forms of human suffering and perversity that follow in the wake of economic development and social change may violate individual standards of morality and increase the probability that oppositional norms and values will be adopted.

A variety of communication interlocks (i.e., multiple group memberships, media diffusion, etc.) serve to link the social, cultural, and individual sources of countercultures together, and create a common universe of discourse which facilitates the invention, propagation, or acceptance of countercultural values (see *Social Networks*).

2.2 Varieties of Countercultures

Countercultures are often distinguished by the values they embrace (or reject), as well as by the methods they employ to promote their values. Although there is an enormous range of inverted values to which counterculturalists may be seen to subscribe, the areas in which opposition to dominant values are most vigorous relate to matters of truth, ethics, and aesthetics (Musgrove 1974, Yinger 1982). That is, the prevailing beliefs and practices of society may be regarded by some countercultural groups as foolish or absurd, evil and immoral, or vulgar and ugly. In response, they may attack the established order and promote alternative values through direct political action or symbolic inversions in the form of art, rituals, or writings.

Some countercultures emphasize the value of transcendental knowledge over knowledge derived from science and rationalism, viewing self-enlight-enment and mystical insights as the only roads to true knowledge and beneficial social change. Intuitive ways of knowing the world can come from within, through meditation, chants, mystical exercises, or 'consciousness expanding' drugs; or from without, through contact with the hidden forces in nature via the occult, the astrological, or the magical (Zicklin 1983). Such practices are designed to dissolve established conceptions of how elements of organic and inorganic life are assumed to relate through time and space, and to call into question the empirical and logical processes of science. The realization of such values requires psychological and/or physical retreat from a world dominated by science and rational calculation, to a place where self-enlightenment and ecstasy can be achieved. Countercultures based on a mystical experiential approach to truth and well-being are epitomized in religious sects of many different periods, and proliferated in the USA during the 1960s and 1970s in the form of such movements as Hare Krishna, Meher Baba, and Maharaj Ji's Divine Light Mission.

Other countercultures may emerge around opposition to hierarchy and privilege, power, and authority, or other perceived obstacles to personal fulfillment and the attainment of the good life. Such opposition may include attacks on technology and bureaucratic controls, on the family and the work ethic, and distinctions based on class, race, gender, and creed. Objections to the quality and direction of social life may come from both the political Left and the Right; the former concerned with institutional reconstruction and the satisfaction of human needs, the latter threatened by the erosion or destruction of old standards and the possibility of status reversals. Each seeks to promote or preserve its vision of the good life through political action, ranging from nonconformist or illegal acts designed to affirm new standards of behavior, to acts of violence or terrorism undertaken to challenge the right of the state to monopolize coercive power. Examples include student activists and Hippies of the 1960s and 1970s (including such extremist or revolutionary groups as the Weathermen and Symbionese Liberation Army in the USA) on the Left, and John Birch Society, Ku Klux Klan, and neo-Nazi groups on the Right.

Some of the more noxious features of advanced technological development which assault personalistic-expressive values or aesthetic norms may galvanize individuals into oppositional groups for the purpose of restoring the balance between sensuality and cold rationality, or creating new standards by which the meaning and beauty of life can be judged. Along with affluence, advanced industrial development is seen to bring in its wake increases in violence, rapacity, and ugliness which pollute the natural and social landscape and impoverish the human spirit.

405

Opposition to such trends finds expression in the aesthetic countercultures of writers and artists of every variety, whose writings, paintings, music, or other creative productions are used to expose the inauthenticity, weaknesses, and absurdities of prevailing values, and to promote alternatives they regard as more aesthetically enriching. The Romantics of the nineteenth century exemplify the countercultural responses of artists to the destructive aspects of technology and change during that period, as does the Dadaist movement in literature and art which emerged in Switzerland, France, and the USA during World War I. Expressions of countercultural themes during the twentieth century can be found in a variety of artistic forms: Surrealism in painting, 'acid' and 'punk' rock in music, and the century-long influence of existentialism on literary works (Yinger 1982).

The preceding does not exhaust the variety of countercultural groups that emerge in opposition to dominant values and practices in a society. Countercultural tendencies are also found among disadvantaged groups, among some individuals engaged in criminal activities, and among those who subscribe to inverted family and sexual practices.

Countercultures are rarely static systems but are usually in a state of flux. Over time, the focal concerns of a group may shift from an emphasis on one set of inverted values to another, or it may attempt to combine different modes of opposition to, and criticism of, the established social order. Such shifts in concerns and approaches often engender internal division and dilemmas which eventually lead to the transformation, incorporation, or demise of the group, or its succession by another.

2.3 Countercultures and Social Change

Although sometimes dismissed as social aberrations or epiphenomena associated with socially and historically specific circumstances, countercultures should be recognized as important sources of social and political change in society. They highlight, dramatize, and communicate the existence of major societal problems, anxieties, and dilemmas (or impending disorders), and give expression to the emergence of new collective sentiments antithetical to the prevailing ethos (Slater 1970). As such, they are vital aspects of the process of social change. To be sure, not all countercultures carry the same implications of social or cultural transformations. Some are relatively isolated, sectarian movements, with little impact on the established order; others may subscribe to inverted values too extreme or dangerous to attract widespread support. But many of the effects of countercultures on social institutions and values are indirect and unintended rather than planned or anticipated. The dissenting tradition created by oppositional movements of mid-seventeenth-century England survived to influence the political history of that country and USA long after the demise of these movements. Likewise, the Hippies of the 1960s and 1970s, whose aberrant behavior and lifestyles were largely rejected during their heyday, have had a significant influence on mainstream American attitudes toward authority, interpersonal relationships, and sexuality. Moreover, many of their innovations in language, music, dress, and art have become accepted styles within the larger society.

Given their profoundly important role in the process of social change, countercultures require the most intensive investigation, both for their creative and destructive influences on society.

3. Conclusion

Every subculture has a distinctive language. This fact is obvious for ethnic subcultures, which at least in part speak the language of their native land as well as that of the surrounding dominant culture. Subcultures that arise from differentiated patterns of social interaction diverge into somewhat separate speech communities, differing both because of language drift and because of distinctive focal concerns. Particularly interesting are subcultures that emerge out of contradictions in the larger society. Linguistic differences are accentuated by the conflict that brings them into existence, and they can develop into full-blown countercultures. Their inversion of dominant values requires them to violate language standards and assert their own vocabulary and even grammar in direct opposition to those of the larger culture that surrounds them. Sometimes they achieve partial success, changing the language of the society, adding their distinctive terms to its vocabulary, and even shifting the values and attitudes that shape social life.

Syntactic Change

N. Vincent

One of the most striking facts about languages is that, given time, they change. The different subsystems of language seem to change in different ways and at different speeds. Thus, neologisms may arise and become current very rapidly, especially with modern methods of mass communication. Conversely, expressions may disappear from usage virtually overnight. Sound changes take longer, spreading gradually through the speakers of a language and through the vocabulary over decades and even centuries. Some changes seem to involve an imperceptible transition from one stage to the next, as when a stop becomes a fricative, e.g., [k > x > h] or [k > c > tʃ > ʃ]; in other instances there is an apparently abrupt shift, as when *holpen* is replaced by *helped* as the past participle of *help*. The patterns involved and the principles required to explain the patterns have been a focus of attention in linguistic inquiry ever since the end of the eighteenth century. Nineteenth-century linguistics in particular saw the development of carefully worked out theories of phonetic and morphological change.

Something of a stepchild in this heyday of the historical approach to language was syntax, for two not entirely independent reasons. First, there were no well worked out theories of syntax, and second syntactic systems are least susceptible to the piece-meal, atomistic treatment that nineteenth-century scholars accorded to linguistic phenomena in general (see *Saussurean Tradition and Sociolinguistics*). This does not mean that earlier scholars had not formulated some profound insights into the workings of change in syntax, as the writings of Georg von der Gabelentz (1891) or Antoine Meillet (1912) will attest. Nor that some of the great compendia of that century's scholarship, such as Meyer-Lübke

(1890–6) or Brugmann and Delbrück (1897–1916), did not contain much pertinent data (see *Sociolinguistics and Language Change*). However, two important twentieth-century developments were required before the fundamental questions underlying change in syntax could be posed and headway then made on answering them. Ironically, this has in turn sometimes led to a revival of the ideas of earlier scholars, Meillet being a notable example in this connection. These key developments are first the Saussurean recognition of the importance of system and structure in understanding the nature of linguistic units. This brought with it the valuable, though in the event overly rigid, dichotomy between synchrony and diachrony. Second was Chomsky's insistence on the rule-governed nature of syntax and later, his formulation of the principles that govern both universal structure and cross-linguistic diversity in this domain. A third development in the twentieth century which has had a notable effect on studies of language change in the field of phonetics, namely Labov's discovery of the principled nature of linguistic variation (see *Sociolinguistic Variation*), has been rather slower to make its impact on syntactic change, but it too is now contributing major new insights into the workings of change in the syntactic component (Kroch 1989).

1. Syntactic Change: The Problem

The central problem of syntactic change can be seen by comparing the Latin and French sentences in (1) and (2) below:

Paulus	dixit	regem	venisse	
Paul.NOM	say.3SG.PERF	king.ACC	come.INF.PERF	(1)

'Paul said that the king had come'

Paul a dit   que le   roi était venu
Paul has said.PP that the.MSG king was come.PP (2)
'Paul said that the king had come'

As the English translations make clear, these two sentences have very similar semantic content, but grammatically they are structured entirely differently. The nouns in Latin bear case endings to indicate their syntactic roles; past time in Latin is referred to here by a single finite verb form—the so-called perfective, where French has an auxiliary *avoir* 'have' plus a past participle; the tense in the embedded clause in Latin is indicated again by a perfective verb form, but this time the infinitive, while French again has the combination of finite auxiliary plus particle, only this time the auxiliary is *être* 'be.' Other notable points are that the subject of the Latin infinitive is in the accusative case, French has an overt marker of subordination in the complementizer *que*, the order of words in French is fixed as that which appears in (2), while the Latin words in (1) could be rearranged into almost any one of the logically possible orders and the sentence would remain grammatical and would have, matters of emphasis apart, the same meaning.

If two genetically unrelated languages, say English and Georgian, were being compared, and a similar catalogue of differences was noted, this would occasion no surprise. The difficulty here lies in the fact that French evolved out of Latin and therefore there must be sequences of change which connect the structures evidenced in (2), for which analogs can be found in all the Romance languages, with those in (1). Moreover, and here is a further puzzle, all the parts of French sentence structure that do not find immediate correspondents in Latin, namely articles, auxiliaries, and complementizers, nonetheless derive from Latin etyma (*le* < Latin, *illum, était* < Latin *stabat, que* < Latin *quod*). The structural properties which characterize the syntax of Latin are clearly different, therefore, from those operative in French, but at the same time the items of French are for the most part reflexes of Latin items.

There is then a paradox of continuity and discontinuity. On the one hand, grammatical systems have an internal structure (rules, paradigms, etc) in terms of which individual items are held in place and, in Saussure's term, motivated. When there are shifts, therefore, these must necessarily be discontinuous as the language moves from one state to another. At the same time there is clearly continuity at some level since communities exist and communication is achieved more or less successfully across generations. The two principal approaches to the phenomenon of syntactic change have taken complementary—though in the long run not necessarily incompatible—views, generativists preferring to give weight to the discontinuity and the abruptness of change while

theorists of grammaticalization have sought rather to emphasize the factors leading to gradual and continuous evolution along language independent, semantically determined paths of change.

2. The Generative Model of Syntactic Change

Although diachronic questions had occasionally been addressed in earlier work, the foundations of a generative account of syntactic change were laid by Lightfoot (1979). Lightfoot (1988) is an updated summary of this position and Lightfoot (1991) represents a reformulation of his ideas in the light of the development of the so-called parametric approach to syntax. A key article in this latter connection is Roberts (1985). The 1980s has seen a considerable burgeoning of generative research into syntactic change, much of it summarized and the theoretical position advanced in Roberts (1993).

The starting point of the generative account is the standard Chomskyan view that languages are epiphenomena which can only properly be understood by investigating the constraints on, and the acquisition of, the grammars that generate them. In particular, there is no sensible notion of the diachronic continuity of disembodied languages, despite the apparent implication to the contrary in traditional formulas such as Proto Indo European *p, t, k > Germanic f, θ, h. Equally there is no continuity at the level of grammars, which die with the speakers who have internalized them. Rather, there is a set of unchanging background conditions, namely the principles of universal grammar (UG) which are hypothesized to be innate and therefore to be available afresh and without prior tutoring to each new generation. Against this background, each learner acquires a grammar on the basis of exposure to the data available in the speech community. The fundamental mode of reasoning here is abductive (cf Andersen 1973): forms must be associated with rules and principles and in the process mismatches and reanalyses may occur. Socially or phonetically induced changes may occur in the data, in virtue of which new associations with rules or principles may arise. Once a speaker has internalized a grammar which incorporates such new associations, new patterns will be observable in the linguistic behavior (performance) which is based on that grammar (competence), and there will thus be constituted a subtly altered pattern of data for succeeding generations, in turn providing the seeds for future abductive shifts. Apart from the limiting conditions of UG, what keeps the process in check is the need to preserve communication between members of the speech community. The effects of overly drastic abductive reorganization will therefore be edited out and a semblance of continuity will be preserved.

The key mechanism of change on the generative view is thus reanalysis: at a particular moment in its history a given structure is capable of two interpretations and a 'jump' occurs as speakers opt for one rather than the other. A favorite example is the history of English modals, which etymologically are clearly members of the larger class of verbs, and with which they share properties such as full inflectional paradigms, the possibility of taking direct objects and of combining with each other. At a certain point, argued in Lightfoot (1979) to be around the beginning of the sixteenth century, a series of exceptional properties build up to such an extent that a new category of modals comes into existence, which then has a history of its own, and does not participate in subsequent changes such as the rise of the periphrasis with *do* in negative and interrogative contexts. Lightfoot's earlier interpretation of this change as involving a somewhat mystical 'transparency principle' was quickly replaced by a more securely grounded analysis in terms of the notion of parameter resetting (cf Roberts 1985). In Old and Middle English morphological inflection had the power to govern verbs and permit them to express their associated arguments. Phonetic changes caused morphological government to be lost, so that only syntactic government was possible; only those items that do not have arguments to express, namely modal verbs, can then occupy the old inflection position, which they proceed to do, thereby changing their superficial syntactic behavior. The option of morphological government vs syntactic government is a parameter which is set differently at different stages of the language. Roberts (1993) documents a number of other such cases, drawing on a wide database of change in word order, morphological marking, distribution of pronouns, etc in English and the Romance languages.

Lightfoot (1991) develops the conceptual underpinning of the parameter resetting model at greater length and takes the opportunity to reply to his critics, particularly those who have sought to argue that change should be seen as continuous and gradual rather than abrupt, and to challenge those such as Allen (1986), who have developed a formal account of change using a lexically-based model of language. The book also contains a valuable discussion of an unduly neglected concept in historical linguistic work, that of obsolescence. Lightfoot argues (1991: chap. 6) that, while new items may arise in languages as a result of spontaneous pressures such as the need for greater expressivity or the effects of borrowing and language contact, old items will only disappear as a result of changes in the system which render them unlearnable to new generations. Obsolescence then is a side effect of parameter resetting and as such a valuable indication

of the working out of a change (cf Vincent 1989 for a brief discussion of this notion).

3. Grammaticalization Theory

Sharply contrasting with the generative approach to the understanding of syntactic change has been that of a number of scholars who have rallied around the concept of grammaticalization (cf Heine et al. 1991, Traugott and Heine 1991, Hopper and Traugott 1993). It is important, however, to distinguish grammaticalization as a mechanism whereby new function words may be generated, which is empirically undeniable and needs to be recognized by any theoretical approach, from the wider philosophy of grammar which links most of those who have taken up the cause of grammaticalization and which is indeed in conflict with many of the fundamentals of the Chomskyan metaphysic which unites scholars such at Lightfoot and Roberts.

The mechanism of grammaticalization is still best captured in the classic definition of Meillet (1912: 133): '*l'attribution du caractère grammatical à un mot jadis autonome*' and examples are legion. Indeed, probably the vast majority of so-called function words in languages—articles, auxiliaries, complementizers, intensifiers, particles of mood, polarity, etc.—are the outcome of such a process of change. Within these changes there are recurrent and cross-linguistically valid directions of development. Thus, English has two periphrases that express futurity: *will* + V and *be going to* + V, and both of these have numerous parallels in other languages. Thus, a future auxiliary deriving from a verb of volition is attested in many of the Balkan languages (Rumanian, Serbo-Croat, Albanian, Greek), and also in Swahili (Heine et al. 1991: 170ff); and from a verb of motion in French, Norwegian, Ewe, Acholi, and Tamil, to name but a few. Other common patterns are complementizers derived from verbs of saying and definite markers derived from distal deictics.

On the basis of evidence of this kind, a number of theoretical conclusions have been drawn. In the first place, grammaticalization is argued to be gradual (Lichtenberk 1991) and therefore not easily compatible with the scenario of abrupt reanalyses required by the generative view. Second, the mechanism at work here is also found in semantic change, where it is traditionally known as generalization. More generally, the categories of metaphor and metonymy used to classify semantic change may also be seen to underly and motivate grammaticalization (Heine et al. 1991: chap. 3). Semantic categories are in turn relatable to pragmatic ones and grammaticalization is often seen at work in the emergence of markers of discourse structure, textual cohesion and speaker's attitude (Traugott 1982). The fundamental motivation for linguistic categories is thence argued to be found in their function in discourse, and grammar is

seen as being determined not by the innate properties of a genetically present UG but by the everyday needs of human communication. On this view categories are fuzzy rather than clearcut, there are only tendencies and not absolute universals, and indeed even the sharp distinction between synchrony and diachrony is called into question. The most extreme proponent of this approach is Hopper, who argues that grammatical categories are secondary and depend on discourse structure for their existence. They are always developing and being replaced so that there is never grammar but only grammaticalization. Once we have reached this point, we have moved a long way from the ontology of grammar which inspires the generative program, and grammaticalization has become a label for an alternative linguistic paradigm rather than simply a type of change (Hopper and Traugott 1993: chap. 1).

4. Relations between Syntactic and Morphological Change

Many of the issues that arise in the domain of syntactic change are also to be found in the area of morphology, a fact which is hardly surprising since it is well known that it is hard to establish a clearcut boundary between the two. Indeed, a large part of the reason for their inseparability is diachronic. Items that at one stage of history have a clearly syntactic function may with the passage of time become morphologized. Thus, the future inflections of the French verb, *chanterai, -as, -a*, etc. are a residue of what in Late Latin was an independent auxiliary which took the infinitive as a complement: *cantare + habeo*, etc. Developments of this kind are clearly a continuation of the process described as grammaticalization above. Givón has argued that the process may go further and that morphology becomes phonology; in other words that what is synchronically no more than a part of the phonemic structure of an item may in fact be an independent meaningful item if one goes back far enough. For example, the *hui* in the French work *aujourd'hui* 'today' is in fact the Latin word *hodie* 'today,' which in turn contains within it the Latin word *die* 'day.' Ultimately even the phonology disappears by processes of phonological attrition and the item goes off the historical stage once and for all.

Meillet (1912) pointed out that grammaticalization also has an important complementary relation to the kind of morphological change known as analogy. The effect of the latter is to be seen if the imperfect forms of Spanish and Italian are compared, both of which have descended from Latin: *amabam, -as, -at* > Sp *amaba, -as, -a* and > Italian *amavo, -i, -a*. The Spanish endings simply continue the Latin ones with due allowance being made for the effects of sound change. In Italian, by contrast, the endings *-o, -i* have been analogically extended from other parts of the verbal paradigm. As Meillet notes, in one sense analogical changes are never productive of new patterns in a language but simply alter the distribution of existing ones. It is only grammaticalization, which can bring into the syntactic system and thence into the morphology new patterns of linguistic exponence. Analogical changes may however contribute to new patterns of form–meaning parallelism, an instance of iconicity at work in linguistic change.

It is to be noted in contrast that analogy as a force in linguistic change does not figure within the generative approach. This is principally because analogy as a pattern of direct connection between form and meaning runs counter to the generative view that any patterns of linguistic structure are mediated by the covert conditions of UG. The generative expectation, therefore, is that the immediate surface distribution of linguistic items will be at best only a partial and indirect reflection of the factors at work in determining that distribution. Some of the effects of what is traditionally labeled analogy do emerge, however, in the generative concept of reanalysis. By the same token, generative grammarians have been less impressed by the wider role of form-meaning iconicity as a factor in understanding language structure and change.

5. The Typological Approach

Theorists of grammaticalization have also been closely involved in or associated with work on syntactic typology which has burgeoned in recent years (see manuals such as Comrie 1989: chap. 10, Croft 1990: chap. 8 for discussion of the diachronic implications of typology). Once again, however, it is necessary to separate the general philosophy of grammar espoused by many of those who call themselves typologists (the term is often expanded to functional typologists—e.g., Givón, Hopper, Li, Thompson, etc.) from the facts of linguistic typology itself, which are neutral as between theoretical approaches and indeed have done much to inform debate in generative grammar in its 'Principles and Parameters' phase. For instance, the original Greenberg correlations about word order properties in natural languages have inspired a considerable literature from scholars seeking to utilize them to explain patterns of syntactic change. These same correlations can equally be reformulated in parametric terms: languages may be 'head first' or 'head last.' Such a parameter shift is intrinsic to the account given by Lightfoot (1979) of the history of *like* in English and to his argument in Lightfoot (1991: chap. 3) concerning the differential development of word order in main and subordinate clauses.

6. The Explanation of Syntactic Change

In the late twentieth century, historical linguists have been greatly exercised by the problem of how to

explain linguistic change, and more broadly, with the philosophical status of explanation in historical linguistics. (See Lass 1980 for an attractive if polemical discussion and Koopman et al. 1987 for a collection of individual studies. Keller 1990 seeks to import into linguistics the so-called 'invisible hand' model of explanation more familiar in the study of the history of economic systems and social institutions.) Theoretical linguists, whether of a structuralist or a generativist persuasion, have tended to prefer the law-based or deductive–nomological model of prediction and explanation found in the natural sciences. The problem here is that there are very few, if any, convincing historical cases of such a model at work. A much more common situation is one in which the linguist can, after the event, offer a plausible scenario of the mechanisms involved in the change while still knowing that it was not a matter of causal necessity that the change took place. Analogical changes provide a very simple instance: it may make good intuitive sense that the irregular past participle *holpen* has been replaced by the regular one *helped*, but it could not have been predicted in advance that the change was bound to happen. Similarly, many changes can be seen afterwards as bringing one aspect of a language's structure into harmony with its other properties, along lines indicated by typological correlations (cf. Hawkins 1983 for extensive documentation and application of this methodology), yet there can be no advance guarantee that such changes will take place. Many languages continue for many hundreds of years in states of typological inconsistency. Similarly, both typological and analogical explanations often run the risk of invoking illegitimate teleological modes of explanation: a given change is argued to have happened *in order to* achieve consistency or eliminate irregularity, without it being clear how either the speaker or the language itself could have influenced change in this way.

One type of explanation that has found a good deal of favor is that based on the presumption of a drive towards motivation or transparency in linguistic structure. This too seems to risk a charge of unjustified teleology, but that has not deterred scholars such as Haiman (1985) or many of the proponents of grammaticalization in the 1990s (for an interesting reflection on iconicity in language from the perspective of generative grammar, see Newmeyer 1992).

Within the field of sound change, great progress has been made in the study of sociolinguistic variation and this has provided a convincing model for the explanation of change in terms of language independent factors such as sex, race, class, regional identity, and so on. Until recently this model had not worked so well when it came to the study of syntax because it could not be guaranteed that variations in form were not motivated by semantic or other structural considerations. It did not therefore seem possible to construct sociolinguistic variables and investigate their correlation with nonlinguistic factors in a simple and straightforward way. However, Kroch (1989) has proposed a way in which this may be done, essentially by considering the unit for the purposes of correlation to be not the individual linguistic form but a grammatical subsystem. In this way, the twin power of formal grammatical theories and sociolinguistic variable analysis may be combined.

The Atlas of North American English: Methods and Findings

S. Ash

1. Introduction

The Atlas of North American English (Labov et al. in press) grew from a pilot project covering six states to a survey of the phonetics, phonology, and processes of sound change in all of North America. From its inception, it has rested crucially on the method of interviewing by telephone in order to sample the largest possible number of speakers over the largest possible geographical area given practical constraints on time and funds. The Linguistic Atlas of the USA and Canada, ambitiously conceived in 1929 and carefully executed under the direction of Hans Kurath for many years, has yielded tremendously rich data (see *Dialect and Dialectology*). However, in the 60 years that have elapsed since the first published reports, when new materials are still being published, dramatic changes have continued to take place in the language. Lamentably, support for the various Linguistic Atlas projects was not enough to provide full coverage of the country. The intent of the Atlas of North American English is to capture a synchronic view of the state of North American English at a particular moment in time. The fieldwork for the Atlas of North American English, comprising about 800 interviews, was accomplished in half a decade, beginning in 1993.

The Atlas of North American English thus presents the first maps of phonetic and phonological variables of North American English as a whole. It must be stipulated that the variety of English under consideration is that of white North Americans. A sample of African-American speakers was interviewed in 1997 and 1998, but those interviews are not included in the Atlas. The African-American community in the USA is linguistically separate from the Euro-American community, and indeed, its vernacular is continuing to diverge from local white vernaculars. Furthermore, African-American Vernacular English (AAVE) (see *Ebonics and African American Vernacular English*) is remarkably uniform across the northern USA, in the vast territory to which African-Americans migrated in large numbers in the course of the massive population movements that began following World War I and were renewed after World War II. This variety of English has been examined in many studies of individual speech communities, but no one has as yet undertaken a survey of the dialect as a whole. The same applies to Southern dialects of African-American English, which are distinct from the Northern dialect and are more differentiated from each other. This needed research is not yet part of the Atlas project.

Given the limitation to white vernaculars of North American English, the Atlas project aims first to define the sound changes in progress that affect large groups of the speakers of North American English. It is not possible to pin down every sound change that is occurring in every community of any size. However, it was known from the outset that dramatic changes were in progress in the phonological systems of large regions, such as the Inland North and the South (Labov 1991), where chain shifts (see *Chain Shifts*) are moving sets of vowels in opposite directions. The goal has been to define the major dialects of North American English in terms of the structure of the phonological system, which entails a focus on the vowel system. The consonantal linguistic variables are comparatively few and do not serve to distinguish regional varieties.

A second goal of the Atlas is to determine the extent of geographic dispersion of the changes in progress that have been described by the many sociolinguistic studies of major cities carried out since the mid-1960s (see *Sociolinguistics and Language Change; Sound Change*). This is the second part of

the riddle of linguistic change: once a sound change is underway, how and where does it spread? Since not all speakers who exhibit a given variant of a linguistic variable use that variant with the same frequency, it follows that sound change spreads from a point of origin, but the manner in which it spreads may be complex. For example, within the state of Oklahoma, Bailey et al. (1993) identified patterns of diffusion along both hierarchical and contrahierarchical lines, as well as contagious diffusion and patterns exhibiting elements of more than one model of diffusion.

Thus the Atlas of North American English is a project for testing theories of language change as well as for describing the state of North American English. It strives to present its object of description at a particular moment in time and to use that object to examine the diffusion of linguistic patterns across a continent.

2. Sampling

The sampling strategy for the Atlas was designed with the goal of representing the largest possible population and focusing on those speakers who were expected to be the most advanced in processes of linguistic change. It has been well established that most sound changes are initiated in urban centers, and since the bulk of the population lives in urban centers, these are the places that are most representative of the population in any case. Accordingly, the USA was divided into areas defined by 145 'Central Cities' to serve as centers of 'Zones of Influence.' The Central Cities are, in most cases, urbanized areas with a population over 200,000, but in order to gain satisfactory geographical coverage, about a third of the Central Cities have smaller populations. The basic plan was to interview two speakers in each of the Central Cities, except that in the 33 urbanized areas with a population over one million, four speakers were to be interviewed. In every city, at least one speaker was to be a woman between the ages of 20 and 40, since these are the speakers who are typically found to be at the forefront of sound change. For a variety of reasons, many additional speakers were interviewed; this adds greatly to the depth and richness of the data and provides further confirmation of the validity of the methods employed through the consistency of the findings that they yield.

3. Selection and Recruitment of Speakers

The most important criterion of an Atlas speaker is that s/he be linguistically a native of the speech community that is being represented. To qualify, a person must have lived in that place at least from the age of four until the end of high school. Preferably, at least one parent is also from the area. For each place which was selected for interviewing, the census records were consulted to determine the most prominent national ancestral groups. Then telephone listings were scanned for listings with surnames marked for the desired national ancestry. When a call was made, the initial interchange with a person who answered the telephone was the identification of the interviewer by name, giving the affiliation with the University of Pennsylvania. This was followed by the explanation that a study of communication among people from different parts of the country was being conducted and the question of whether the speaker had grown up in the town where s/he was located. If the answer was affirmative and the speaker was willing to be interviewed, permission to record the interview was requested.

Locating speakers in some places was difficult because speakers with the desired credentials were comparatively few. In Queens County, New York, for instance, 28 percent of the residents are not native-born Americans, according to the 1990 census. In addition, 22 percent are African-American and 20 percent are Hispanic.

Another problem is social class. Most sound changes come about below the level of conscious awareness, and such innovations typically arise in the lower middle and upper working classes. We can rely on finding a shared structure of the phonological system throughout a speech community, but to be confident of having representation of the newest changes in progress, it is necessary to collect data from those speakers who are most likely to be the leaders of linguistic change in the community. Therefore, it is essential that the Atlas sample include speakers from the interior social classes (i.e., the upper working class and the lower middle class).

A complicating factor is that the incidence of unlisted telephone numbers increases rapidly with decreasing social class, which presents an obstacle to obtaining adequate representation of the social classes below the middle on the social scale. (For working class people, a telephone listing makes an individual available to bill collectors, sales people, survey takers, and other undesirable outsiders. The attributes of a telephone listing that are seen as advantages by the upper middle class do not apply.) Nonetheless, the Atlas speakers do provide good representation of all social classes. A modest deficit in the number of upper working class speakers as compared to the general population is compensated for by a relative surfeit in the number of middle middle class speakers. These middle middle class speakers may not be on the cutting edge of linguistic change in progress, but they can still be expected to be solid representatives of both the entrenched and innovative forms of the speech community.

Still, for some variables social class is critical. For example, in New York City the status of postconsonantal /r/ is a crucial issue. /r/-vocalization is waning fast among upper middle class speakers, so its status

413

had to be determined in the working and lower middle classes, where vocalization historically has been very high.

The problem of locating the ideal speaker—an upper working or lower middle class white person who is native to the place of interest—out of millions of phone listings is handled by further consultation of the census reports. The Census Bureau provides data by census tract on a variety of social variables, including nativity, ethnicity, and educational attainment, the last of which is directly correlated with social class. Census tracts are small, with an average population of about 4000, and so restricting telephone calls to a census tract with the desired demographic characteristics produces a high rate of success in the effort to contact the ideal speaker.

4. The Atlas Interview

Following the introduction, in which the interviewer identifies her/himself, obtains permission to record, and establishes that the respondent is a native of the community where s/he lives, the interview is divided into six sections.

(a) It begins with a section on demographic information that records the native and local status of the respondent: place of birth, complete residence history, father's and mother's places of birth, and languages spoken.

(b) The largest portion of spontaneous speech is obtained from a discussion of recent developments in the city, the state of the downtown area, and travel outside the city. If a topic of special interest to the speaker is raised, it is pursued to the fullest extent possible. Speakers often talk about their jobs, hobbies, or other interests in this portion of the interview.

(c) The respondent then provides word lists that do not require reading: counting, days of the week, articles of clothing, and others.

(d) The next portion of the interview is devoted to specific linguistic variables. The most formal parts use minimal pairs in the form of judgments on rhyming (*sock* vs. *talk*) or same versus different (*pin* vs. *pen*). In each case, the respondent is asked to say the desired word without its being pronounced by the interviewer and then to make a judgment on the contrast or identity of sounds.

Spontaneous pronunciations of crucial lexical items are obtained through the use of the semantic differential technique (Labov 1984), which uses questions about differences in meaning between two words, such as *cot* vs. *bunk* and *pond* vs. *pool*. Such questions often produce a considerable volume of speech, including several highly stressed tokens of each word without attention to the pronunciation. Previous research shows that the use of the variables

in the semantic differential approaches the values of spontaneous speech quite closely (Labov 1989).

(e) When the elicitation of linguistic variables is complete, more detailed information on the demographic background of the subject is gathered, including occupation, education, and national ancestry.

(f) The final section is the request for the respondent to continue participation in the research by reading a word list, which is to be mailed to the speaker. This requires that the speaker provide his or her name and address. A small number of speakers decline to give this information or refuse to participate in this second part of the interview, and some ask for additional reassurance that they will not be subject to solicitations from salespeople or other unwanted callers. Most speakers readily agree to the follow-up interview and greet the interviewer as a familiar acquaintance when s/he calls again. The duration of the first interview averages about 30 to 45 minutes, ranging from 20 minutes to well over an hour.

5. The Follow-up Interview

The second interview is designed to obtain more specific information on lexical distribution through the reading of a word list and more detailed information on contacts outside the community. It begins with the speaker reading the full-page list of words which had been sent to them in the mail (or occasionally by email) after the first interview. The word list covers the areas of variable contrast and variable lexical distribution in the speaker's region, as well as a fairly complete inventory of the phonological system as a whole. The second interview also goes more deeply into the patterns of travel, friendship, kinship, and communication that relate the respondent to other cities in the region.

6. Impressionistic Coding

The first stage of analysis is the transcription of all demographic data, recording of lexical choices and judgments of syntactic constructions, and the coding of the speaker's pronunciation of diagnostic words in the formal part of the interview. For the phonological variables, the analyst records both the speaker's and the coder's judgments of 'same' and 'different' and then enters a narrow phonetic transcription of the speaker's pronunciation.

7. Acoustical Analysis

Instrumental analysis of the entire vowel system has been carried out for more than half the speakers who have been recorded, using the CSL hardware and software package from Kay Elemetrics. The recordings are digitized in sections, and words bearing full sentence stress are segmented and saved.

Spectrograms are produced for each saved word, formant trajectories are calculated by linear predictive coding, and one point in time is selected to represent the stressed vowel. The corresponding F1 and F2 measurements are written to a log file with a record of the point that was selected, a code for the classification of the vowel, and comments where appropriate. The formant values are normalized using the log mean normalization procedure (Nearey 1977) on a speaker population of 345, and the vowel system is charted using the Plotnik program (Labov 1997). (See Boberg forthcoming, for a full description of these procedures.) The total volume of speech obtained proved to be more than was expected from the earlier telephone survey of Hindle (1980). Ninety percent of the speakers are charted with at least 200 vowels, and half have provided 300 or more.

8. Findings

What, then, are the dialect areas of North American English? Figure 1 maps the areas established by the Atlas. As will be seen, a fairly limited number of phonological features determine these dialect areas. A full discussion of these features, the configurations they create, and the rationale on which the divisions rest is the subject of the Atlas itself and will not be attempted here. The following is rather an inventory of the features as they determine the major dialects of North American English. Many of these features apply in discontinuous regions, in a distribution that depends heavily on settlement history and subsequent population movements. The feature that perhaps makes the greatest cut in North American English (in terms of area and number of speakers) is the presence or absence of the unconditioned merger of /o/ and /oh/, as in *cot* and *caught, Don* and *dawn, hock* and *hawk, collar* and *caller*. Not only does this merger have the structural consequence of reducing the number of entities in the phonemic system, but it also produces a large number of homonyms, as is implied by the list of examples given. Plausibly, this merger has come about as a result of crowding in the low back corner of the vowel space.

A second feature that plays a prominent role in distinguishing the major dialects of North American English is the position, on the front-to-back dimension, of the nuclei of the back upglides, /uw, ow, aw/, as in *boot, boat,* and *bout.* The initial position for these vowels is taken to be at the back of the articulatory space; many dialects depart from this pattern in significantly fronting one or more of these vowels. The fronting frequently does not apply to allophones of the vowel preceding liquids, which form a special class in many cases of sound change. /uw/ is being fronted generally, although it is most advanced in the South and the Midland and seems to be just getting underway in the North. /aw/ distinguishes the North from other regions, as the

North is characterized by /aw/ being further back than /ay/. Of this set of vowels, /ow/ does the most to differentiate the dialects of North American English. The status of the /o/-/oh/ merger and the fronting of /ow/ with respect to the major dialects is as follows:

/o/-/oh/ merged	fronting of /ow/
Canada	no
Eastern New England (except Providence, Rhode Island, where there is no merger of /o/ and /oh/, but r-vocalization prevails)	no
North Central region	no
The West	advances gradually from north to south
Western Pennsylvania	yes

/o/-/oh/ distinct	fronting of /ow/
Western New England	no
Inland North	no
Central Midland	yes
Mid-Atlantic region	yes
The South	yes

The characterization of dialects by these two features covers much ground, but the sum is a patchwork which is incomplete. The following paragraphs will review the four major dialects by region—North, Southeast, Midland, and West—and distinguish the subregions included in each. The North consists of the subregions of Canada, Eastern New England, Western New England, the Inland North, the North Central region, and interstitial areas, south to and including New York City.

Canada is distinguished from the USA by the Canadian Shift, first described by Clarke et al. (1995). This chain shift, the lowering and backing of /i/ and /e/ and the backing of /æ/, is found throughout English-speaking Canada, except for the Atlantic Provinces (New Brunswick, Nova Scotia, Prince Edward Island, and Newfoundland). So-called 'Canadian raising,' the centralization of the nuclei of /ay/ and /aw/ before voiceless obstruents (Joos 1942, Chambers 1973), is also found throughout Canada, including in the Atlantic Provinces. The centralization of /ay/ before voiceless segments is characteristic of much of the North of the USA as well, though centralization of /aw/ is not.

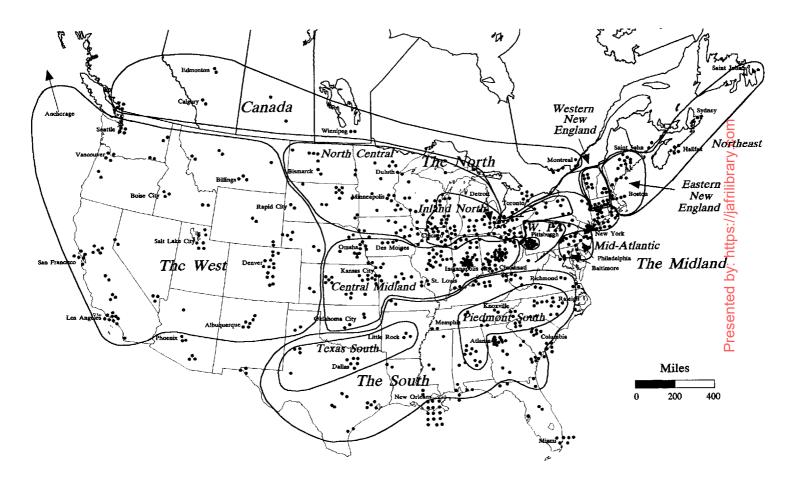
Two noncontiguous regions, Eastern New England and the North Central region, share the merger of *cot* and *caught,* along with the retention of back /ow/, which is characteristic of the North generally. These two subregions are differentiated from each other by preconsonantal /r/-vocalization, which is found in Eastern New England (as well as in New York City) but not further west.


Figure 1. Dialect areas of North American English. (Each dot represents one Atlas speaker).

The remaining regions of the North are areas in which /o/ is distinct from /oh/. The Inland North, the industrial region stretching along the Great Lakes from western New York State to southern Wisconsin, is distinguished by the Northern Cities Shift. This is a dramatic rotation of six vowels, without restructuring of the phonemic system by merger or split. In this chain shift, /æ/ is tensed and raised as a whole (*tack* becomes a high, ingliding vowel, moving in the direction of *tech*), short /e/ is either backed or lowered (*tech* goes to either *tuck* or *tack*), /–^–/ is backed and rounded (*tuck* goes to *talk*), long open /oh/ is lowered and fronted (*talk* goes to *tock*), and short /o/ is fronted (*tock* goes to *tack*). Like the Inland North, Western New England is a conservative area with respect to the back upglides. It also shows some evidence of the Northern Cities Shift in the relative positions of short /e/, which is backed, and short /o/, which is fronted.

The vast Midland area, stretching from the East Coast to the Great Plains, is unified by the fronting of /ow/, which is not found in the North, and the near-absence of /ay/-monophthongization, which characterizes the South. (/ay/-monophthongization occurs in the Midland sporadically in the most favored environments, before liquids and nasals, e.g., in *mile* and *time*.) Otherwise, within this region there is diversity, in which each big city seems to have its own cluster of special characteristics. The easternmost cities—Philadelphia, Wilmington, and Baltimore, which comprise the Mid-Atlantic region—show a phonemic split of /æ/ into tense and lax classes, /æh/ and /æ/. (This split, with a superset of tensing environments, is shared by New York City, as is mentioned above, but New York is nonetheless part of the North, based on other lexical and phonological criteria.)

Western Pennsylvania is a subregion of the Midland centered on Pittsburgh. This is the one Midland city in which /o/ and /oh/ are fully merged, and it is unique in that /aw/ is fronted and monophthongized to /ah/.

West of Pennsylvania is the Central Midland. Cincinnati is distinguished by a short *a* system that is unique in the Midland. Short *a* is a single phoneme, but the distribution of allophones echoes that of New York City: words with following alveolar fricatives (*cash, hash*) and with following voiced stops (*sad, bad, mad*) have short *a* in the highest and frontest portion of the distribution.

St. Louis is another special case. It is losing its characteristic merger of *card* and *cord* and re-aligning itself with the North; as a result it shares many features with Chicago. Other features are generally shared by the Midland cities. While the Midland is considered to be a region in which /o/ and /oh/ are distinct (except for Pittsburgh), there is in fact a weakening of the distinction for many speakers.

Throughout the Midland, and to a greater extent than anywhere else, there is also a weakening of distinctions among back vowels preceding /l/, as in the pairs *full-fool, bull-bowl, gull-goal*, and *skull-full*. Every Midland city except Philadelphia and St. Louis exhibits this feature to some extent.

The most general definition of the South is that it is the outer limit of the area in which /ay/ is monophthongized finally and before voiced obstruents. This definition excludes Florida; however, a broader definition of a Southeast region as the area in which /ow/ is at least moderately fronted and the distinction of /o/ and /oh/ is maintained in perception includes this highly populous state.

Within the South, two core areas are defined, the Inland South of the Piedmont and the Texas South. These are regions where the monophthongization of /ay/ has advanced to the environment preceding voiceless obstruents and the Southern Shift has advanced to the point of a reversal of the relative positions of /i/ and /iy/ as well as of /e/ and /ey/.

The West is set apart from other dialects that have the merger of /o/ and /oh/ by exhibiting strong fronting of /uw/ but not /ow/. However, this must be qualified. In roughly the northernmost third of the region, /ow/ is fully back. In the middle third of the region, /ow/ is slightly fronted, and in the southernmost part, /ow/ moves still further in the direction of the South. Nowhere in the West, however, do speakers attain the degree of /ow/-fronting that is found in the South and the Midland.

The Atlas of North American English thus provides a sense of the structure and pattern of North American dialects and of the richness and vigor of ongoing sound changes in North American English today.

Urban and Rural Forms of Language

A. M. Hamilton

Dialect geographers use the terms *urban* and *rural* to classify communities, and by extension, the speakers who live in those communities. There are no language features that can be associated with either an urban or a rural environment regardless of region, but there certainly are scholarly assumptions regarding what constitutes urban and rural forms of language. Modern evidence has led to a reexamination of the traditional assumptions that a rural community, by virtue of low population density and insularity, will tend to preserve archaic speech features, while an urban community, by virtue of high population density and the continual influx of outsiders, will fail to preserve archaic and regionally marked speech features.

1. Assignment of Urban and Rural Classifications

Dialect corpora differ with respect to the assignment of *rural* and *urban* to targeted communities, but generally base their definitions on population density. For example *The Dictionary of American Regional English* (1985) distributed its data collection among five types of communities, ranging on a scale from urban to rural, the extremes of which are: (1) *Urban*: a specific section within a metropolitan area, with a population usually in the thousands within a total of a million or more; and (5) *Rural*: an area with unconcentrated population—farm dwellings, small crossroads settlements—and a population in the hundreds (Cassidy 1985: xiii). The definition of urban and rural community types for the *Linguistic Atlas of the Middle and South Atlantic States* (LAMSAS), on the other hand, is based directly on 1940 US Census specifications: any city or town with more than 2500 inhabitants was classified *urban* (Kretzschmar and Schneider 1996: 68).

2. The Traditional Preference for Rural Informants

While the labels *rural* and *urban* were assigned to a speaker on the basis of community type, the labels also suggest the value of the speaker for early dialect researchers. The preference for rural folk speakers in dialect research began with the European survey methods of Gilliéron and Edmont's French Atlas (1902–10) and Jaburg and Jud's Italian/Swiss Atlas (1928–40) (see *Gilliéron, Jules*; *Jaberg, Karl*). European villages were known to preserve older forms of language and maintain features that distinguish them from even nearby villages. While dialect features vary more gradually across the USA than across Europe, there is still a tendency for rural areas of the USA to preserve regionally marked speech features, so dialect geographers of the USA adopted the preference of European researchers for rural speakers during the early twentieth century (see *Kurath, Hans*).

An ideal *rural* speaker is one who has resided in a sparsely populated locale all his life—usually a region with a farm based economy—and is therefore expected to speak with features representative of his geographic location. *Urban* speakers were less valuable in early dialect studies because they were expected to have associated with a great variety of regional groups, and were therefore assumed to be less representative of their locale linguistically.

3. The Evolution of Assumptions

The growth of cities in the USA during the twentieth century has challenged early assumptions about dialect preservation in urban communities. While generally there is a tendency for regional dialect features to be erased in an urban environment for the educated middle class, there may be a covert prestige force motivating the working class to differentiate itself from the upper classes by maintaining the local vernacular. In this sense, the urban area is as likely as the rural area to preserve local speech features for members of certain socioeconomic classes (see *Sociolinguistic Variation*).

At the same time, assumptions that rural communities preserve regional identity have not been revised in light of new data. Johnson's (1996) comparison of dialect survey data in the Carolinas and Georgia from 1930 and 1990 demonstrates that urban/rural community type accounts for the same amount of variation in each survey. So rural/urban community type remains an explanatory factor for language variation.

4. Some Observed Differences Between Urban and Rural Speech

Generally, we expect rural speakers to use more precise lexical forms that refer to ranching, farming, and animal husbandry, while urban speakers ill show relative ignorance about such terminology. We also expect rural speakers to preserve older forms of speech based on the assumption that language changes occur at a relatively slower rate in areas of lower population density relative to areas of high population density. The three major types of linguistic features that can be more or less closely correlated with a rural or an urban identity are lexical, phonological, and syntactic features.

Lexical features reflect cultural and occupational differences between rural and urban communities. Johnson's (1996) analysis of rural and urban lexical differences in the Carolinas and Georgia revealed more older forms associated with rural identity. A prime example is the older rural form *polecat* for the newer *skunk*. The lexical form *living room*, on the other hand, is a newer variant significantly associated with urban affiliation (Johnson 1996: 67).

Phonological differences between urban and rural speakers are also based primarily on degree of insularity and cultural identity. For instance, farmers and ranchers in the El Paso, Texas region preserve more East Texas and Southern phonetic features than their urban counterparts, due to their relative isolation from city life. One example is the monophthongization of /ay/, in words like *line*, which is correlated only with rural El Paso native speech (Hamilton in press). This observation of the association between rural identity and an archaic phonological feature supports the notion that rural communities preserve archaic speech features.

Syntactic differences between rural and urban groups are less tangible, though the assumption persists that rural speakers can be expected to use a nonstandard system of grammar in a conversational setting. Just as they have been demonstrated to preserve archaic lexical forms and phonological features, rural speakers may also preserve archaic syntactic features.

A familiar example is a-prefixing on -*ing* participles in the Appalachian and Ozark regions, where a speaker might say, 'We was *a-huntin'* all day' (see Christian et al. 1988: 51–84). The mountainous geographic features of the Appalachian and Ozark regions have discouraged urban development and have thus maintained isolation of speech commun-ities, thereby encouraging preservation of a-prefixing.

The emphasis of urban schools on prescriptive grammar serves to discourage nonstandard syntactic features in the educated urban middleclass. However, nonstandard syntactic features in an urban setting can be observed in neighborhoods that limit socio-economic and ethnic variety.

While urban and rural linguistic differences are observable on a local level, nothing suggests that individual features are associated with either a rural or an urban identity, regardless of region. This is not unexpected, since rural and urban classifications are not linked to homogenous groups of speakers in any sense other than farming and ranching occupations for a limited number of rural speakers.

5. Future Work

Research in language variation is likely to continue exploration of the extent to which dialect leveling or preservation occurs in both rural and urban communities. Of particular interest is the perception and possible reality of a standard register developing in urban communities among educated participants in mobile urban culture, those who move from city to city for professional advancement.

Vernacular
R. Macaulay

The term vernacular is used in two distinct ways. One is to refer to a separate language as in the 1953 UNESCO definition of a vernacular: 'A language which is the mother tongue of a group which is socially or politically dominated by another group speaking a different language' (UNESCO 1953: 46). This use is relatively uncontroversial.

The second use is with reference to a form of language (usually speech) that is held to differ in significant ways from the socially approved prestige or standard language. It is this latter use that has concerned many sociolinguists, although no clear definition has been established.

1. Vernacular as Non-standard Dialect

A recent collection of articles on nonstandard syntax states:

> ... we will mainly use the term *vernacular syntax* to refer to those features that are uncontroversially not part of the established standard ... we mean by *vernacular* those features that are situated at some distance from the formal written pole, and more towards the vernacular spoken pole. We will also use the terms *nonstandardized syntax* and *spoken syntax* without attempting to distinguish between them. (Cheshire and Stein 1997: 2)

In this definition there are the oppositions standard/nonstandard and written/spoken and it is not clear which is primary. A further problem is that the terms standard and nonstandard are themselves ambiguous (Macaulay 1973).

2. Vernacular as Unwritten Language

Sociolinguists who are studying the social uses of language are usually interested in differences in the spoken language that may not be represented in the written standard. There has been uncertainty about the labels to apply to varieties of the spoken language that differ significantly from the standard form. The words dialect, basilect, low variety, and vernacular have been used in different situations. The term dialect is most frequently used with reference to regional varieties, usually those with a long history (see *Dialect and Dialectology*). The term basilect is generally restricted to creole situations in which there is a continuum ranging from the acrolect with the highest prestige to basilect at the bottom (see *Pidgins and Creoles: An Overview*). The term low variety is used in diglossic situations where there is a distinct contrast between a high variety and a low variety (see *Diglossia*).

3. Vernacular as Non-official Language

The traditional use of the term vernacular was to refer to an independent language that had not been accepted as the language for official transactions or intellectual endeavors (Macaulay 1988). In this sense, English and French were vernaculars when Latin was used as the medium for serious written communication. Until recently, languages such as Breton, Occitan, and Corsican could similarly be considered vernaculars. In present-day Africa most tribal languages are vernaculars in this sense.

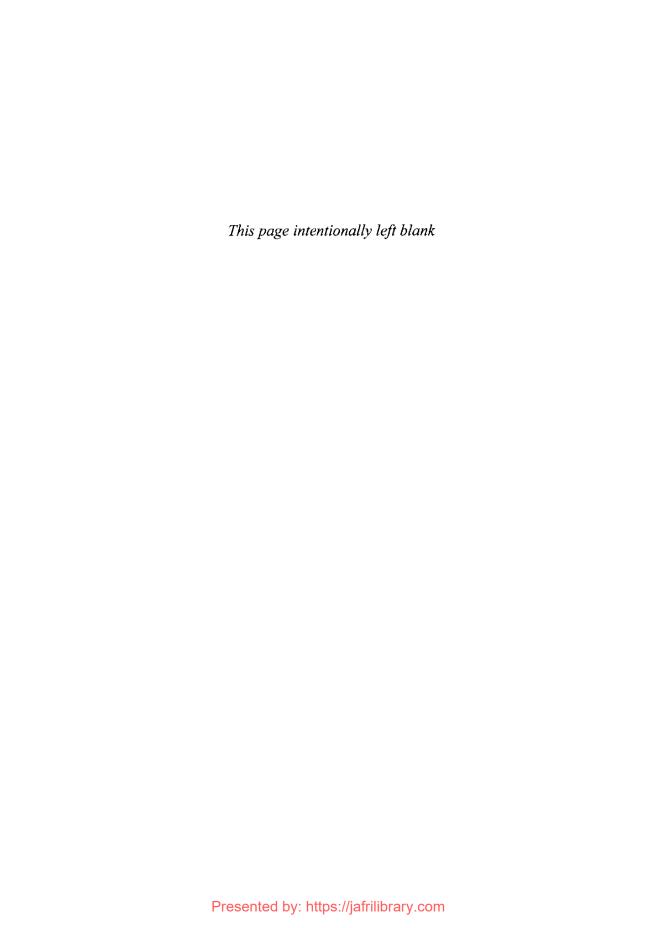
4. Vernacular as Colloquial Speech

In sociolinguistics the term vernacular was popularized by Labov, who used it to avoid the negative connotations of early labels such as Nonstandard Negro English, which he had used previously. Unfortunately, Labov extended his use of the term vernacular to other situations which are less clearly defined. The most problematic of these is given in Labov (1970: 46) where the vernacular is defined as 'the style in which the minimum attention is given to the monitoring of speech.' This is similar to the term casual speech used in Labov (1966: 100): 'By casual speech, in a narrow sense, we mean the everyday speech used in informal situations, where no attention is directed to language.'

Labov also claims that 'the most consistent vernacular is spoken by those between the ages of 9 and 18' (1973: 83) and defines the vernacular as 'that mode of speech that is acquired in preadolescent years' (1981: 3). This led him to a potentially confusing claim:

> There are communities where the basic vernacular is a prestige dialect, which is preserved without radical changes, as the adolescent becomes an adult. The class dialect used in British public schools [i.e. private boarding schools] had that well-formed character, and presumably a British linguist raised as a speaker of Received Pronunciation can serve as an accurate informant on it. (Labov 1973: 112)

All RP speakers are presumed to speak Standard English, though not all speakers of Standard English have an RP accent. Labov's claim would imply that there could be vernacular speakers of the standard language.

5. Conclusion: Vernacular: a Polysemic Term


The use of the term vernacular will probably remain confusing until there is a clear distinction between a language and a dialect, a situation that is unlikely to be resolved soon (Macaulay 1997b). In the meantime,

it is likely that vernacular will be used in multilingual situations to refer to those languages that are not widely approved for use in education, official communications, and the media. In monolingual situations the term vernacular will probably continue to be used with reference to a spoken variety that is deemed by some criterion to differ from the standard variety and that is not endorsed by the educational system, though its definition may remain fuzzy. This situation will trouble only those who seek clarity and precision in this murky area of linguistic terminology.

Language Contact

Areal Linguistics
J. M. Y. Simpson

Geographical areas can be identified in which the languages spoken are not necessarily genetically related but are nevertheless characterized by features in common not found in languages outside the area. The identification of such areas and the consideration of the processes by which they come about are the concerns of 'areal linguistics.' This concentrates on similarities between languages and on language convergence and is particularly concerned with languages that are not genetically related. In this respect it is complementary to historical linguistics which is primarily interested in the ways in which genetically related language varieties grow apart with the passage of time, that is, it concentrates on language divergence. The concerns of areal linguistics overlap with those of dialect geography and of sociolinguistics and are illuminated by the findings of these related studies.

This article deals in turn with possible types of similarities, with the ways in which similarities spread and suggested reasons for this, with the nature of such geographical areas, and finally with some problems within areal linguistics. (Areal phenomena affecting genetically related languages are not avoided.)

1. Genesis of Areas of Similarity

Concerning such areas of similarity, it may sometimes be inferred that the features in common were originally present in only one of the varieties and subsequently spread to the others. The necessary condition for this situation is that at least one person must have had some knowledge, however minimal, of more than one variety of language. These varieties may be extremely close genetically or quite disparate.

1.1 Lexical Borrowing

Speakers may indulge in 'code-switching'; that is, they may use more than one variety of language in the course of conversation. The reasons for such code-switching may be the nature of the topic under discussion or the different linguistic abilities of speaker and hearer (see *Code-switching: Overview*).

The duration of stretches in different varieties can vary considerably, but it is possible that a speaker of variety A may introduce only one word X in a different variety B before reverting to A; this can take place, for example, because there is no name in A for the object to which X refers. (It is in fact perfectly possible that the speaker's active knowledge of B is limited to this one word X.) Thereafter the speaker and an increasing number of other users of A will employ X as a normal word in A. This process accounts for the phenomenon of *borrowing* by which a variety of language is said to acquire items of vocabulary from another language; thus English has acquired—among thousands of borrowings from other languages over the centuries—*spaghetti* from Italian, *nuance* from French, *kayak* from Inuit and *kangaroo* from one of the Australian languages (see *Borrowing*).

Where such borrowings concern entities or concepts previously unknown to speakers of the receptor language (as in the above examples), they may be informally termed examples of 'exotic borrowing.' These may be from any other language in the world and therefore will not necessarily have any implications for areal linguistics.

However, while much borrowing is understandably of the 'exotic' type, sometimes existing native words, even those from what could be termed the 'inner core' of the vocabulary, are ousted by borrowings. (By the 'inner core' is meant numerals, pronouns, minor parts of speech such as particles and prepositions, words for parts of the body, for blood relatives, for natural entities such as sun, moon, stars, water, sky and so on.) Indeed there seems to be no limit on what core words can be borrowed: Russian borrowed its numeral for '40' from Greek; English took the pronouns *they* and *them* from Norse; *plus* and *via* from Latin are used in English as conjunction and preposition respectively; *stomach* came via French from Greek; *aunt* and *uncle* came via French from Latin, as did *river*. This phenomenon could be informally termed 'core borrowing'; it implies a much greater active knowledge of the donor language

on the part of the original borrowers and can have implications for areal linguistics. Thus the presence of *stomach* and *river* in English (contrasted with their absence in German) would allow us, in these particular respects, to contrast English and German (Germanic languages) and group English with French (a Romance language).

1.2 Grammatical Borrowing

Speakers may also transfer grammatical features from one variety into another. This can be termed 'grammatical borrowing' and could be regarded as a kind of imperfect code-switching since the change of variety is not complete, one aspect—the grammatical—being, so to say, 'left behind.' For example, the Scottish Gaelic and Irish equivalent of the English *I have just said that* is 'I'm after saying that,' involving a preposition and a verbal noun. Speakers of nonstandard English from the West of Scotland and Ireland may produce utterances such as *I'm after saying that*, even though ignorant of Scottish Gaelic or Irish. The assumption is that on some occasions in the past Gaelic-speakers with a less than perfect command of English produced an example of imperfect code-switching in the form of a literal translation of what they would have said in their native tongue; this new syntactic construction was then imitated by other speakers, including in time those who knew only English. The result is that the variety of English in which this construction is found is in this respect grouped with geographically contiguous Irish and Scottish Gaelic (Goidelic languages) in contrast to other varieties of English.

To take two further examples: speakers of the Semitic languages of Ethiopia have adopted the SOV word-order and various other syntactic devices of neighboring Cushitic languages; Osmanli Turkish introduced certain Arabic and Persian conjunctions and with them subordinate clause constructions containing finite verbs, thus displacing native Turkic verbal noun and participial constructions (see *Language Transfer and Substrates*).

Morphological devices and grammatical categories, too, may be borrowed for the same reason. Thus speakers of Spanish in Paraguay may borrow a nominal tense-marker from Guarani (e.g., *mi novia-kue*', my girl-friend-PAST'='my ex-girl-friend'). Such devices may be imitated in a different phonological form: Romanian *om, omul* (the latter from Latin *homo ille*) is paralleled by Albanian *burr, burri* and Bulgarian /tʃovek/, /tʃovekət/—each pair is respectively 'man,' 'the man.'

An example of a feature disappearing is seen in the geographically contiguous group of Armenian, Persian, and Turkish; these are distinguished by a lack of grammatical gender. Since many other Indo-European relatives of Armenian and Persian do show gender, it is possible that the latter have lost it under the influence of Turkish.

All these are examples of how contiguous languages can in some grammatical respect become similar and hence different from their genetic relatives. For instance, the Albanian, Bulgarian, and Romanian definite articles mark off a geographical Balkan group in contrast to the genetic relatives of Romanian (the other Romance languages have a preposed definite article) and of Bulgarian (other Slavic languages have no definite article).

1.3 Phonetic and Phonological Features

It can be the case that the phonology of the receptor language is expanded to accommodate possibilities offered by the borrowed word: for example, native Welsh words do not begin with /tʃ/ but the volume of potential borrowings from English (such as *chips*) with this initial cluster together with the bilingualism of Welsh speakers have ensured that this is now the initial cluster normally pronounced in such borrowings into Welsh. Changes in phonology of this kind are again relevant to areal linguistics, for in this respect Welsh is grouped with English in contrast to its genetic Celtic relative Breton.

When individual speakers of one variety of language acquire another they may retain features of pronunciation of the first variety and use them in the new one; they will have, in everyday words, a 'foreign accent.' When a group of speakers with the same native language acquire a new variety the situation is no different. It is claimed that when Gaulish speakers acquired Latin, they could not pronounce the rounded close back vowel [u] (roughly the vowel in English *boot*) found in Latin *murus* 'wall' but substituted instead a rounded close front vowel [y], the sound still heard in French *mur* 'wall.'

In this particular case of language-contact, Latin can be regarded as the *superstratum* ('the language of a conquering or dominant group') because of military and cultural factors. Nevertheless it is Gaulish, the subservient language or *substratum* ('the language of a conquered or subordinate group'), that exerted an influence on the new language of the population. In this particular respect French is marked off from Standard Italian and Spanish, its Romance genetic relatives and neighbors, for they do not possess the sound [y]. (See *Language Transfer and Substrates*.)

New sounds may develop in a language as a result of internal development, as in the appearance of retroflex consonants in the Indo-Aryan languages. The borrowing of words containing these sounds from the neighboring Dravidian languages resulted in the status of retroflex consonants being strengthened in that they were used more frequently and in new phonetic environments. A noncompeting neighboring language which has effects of this kind can be

Table 1. The geographical limits of certain German sound changes.

	k->kx- 'child'	p->pf- 'pound'	-t>-s 'that'	Vp>Vf 'on'	-rp>-rf 'village'	VkV>VxV 'make'	-k>-x 'I'
Zürich	Kchind	Pfund	das	auf	Dorf	mache	ich
Freiburg	Kind	Pfund	das	auf	Dorf	mache	ich
Heidelberg	Kind	Pund	das	auf	Dorf	mache	ich
Trier	Kind	Pund	dat	auf	Dorf	mache	ich
Luxembourg	Kind	Pund	dat	op	Dorf	mache	ich
Aachen	Kind	Pund	dat	op	Dorp	mache	ich
Düsseldorf	Kind	Pund	dat	op	Dorp	make	ich
Kaldenhausen	Kind	Pund	dat	op	Dorp	make	ik

referred to as an *adstratum*. It may be that a language borrows totally new sounds from an adstratum; this seems to be the case in Xhosa and Zulu (Bantu languages) which use clicks, frequent in neighboring Khoisan languages but absent in other Bantu languages.

2. Wave Theory

Emphasis on the spatial spread of language changes was laid by Johannes Schmidt in the nineteenth century in his *wave theory* (*Wellentheorie, Ausbreitungstheorie*), though the point was also made by Hugo Schuchardt (see *Schuchardt, Hugo*). This visualizes a language change as operating from a geographical point and spreading outwards, like ripples resulting from a stone being thrown into water. It is assumed that, consciously or unconsciously, individual speakers will have successively imitated or acquired some desirable linguistic feature. But eventually the expansion ceases, leaving an area of change surrounded by an area where the change has not occurred. For example, about the sixth century CE several sound-shifts in German spread northwards from the area of present-day Switzerland. Each halted on a different line. Seven of them and their end-points are indicated in Table 1. The test words are quoted in modern German orthography (⟨ch⟩ = [x]) (see *Dialect and Dialectology*).

These sound-changes, though involving similar phonetic processes and operating in the same geographical direction are independent: in fact at the western end /VkV > VxV/ halted before /-k > -x/ giving in Düsseldorf *ich make*, but further east /-k > -x/ halted before /VkV > VxV/ giving in Berlin *ik mache*. The dialect picture resulting from these and associated changes is complex, and it is made even more fragmented by over a dozen other changes which spread out from different points in the middle of the area (Keller 1961: xii–xiii).

In that instance, the varieties of language are related and geographically close ones will be mutually intelligible. However, in wave changes the varieties involved need *not* be mutually intelligible. In other words, wave-expansions affect not only what

are regarded as dialects of the same language, but also quite different languages.

For instance, one particular phonological feature is found in Finnish, Saami, dialects of Norwegian and Swedish, and Icelandic. This is a sequence of voiceless vowel (an h-sound) followed by a voiceless plosive, as in Finnish *lehti* 'leaf'; it is known as pre-aspiration. These languages are not mutually intelligible, indeed Finnish and Saami belong to one family, the Uralic, while the others belong to another, the Indo-European. Since they are spoken in geographically contiguous areas it is tempting to regard this pre-aspiration as the result of a wave change which passed from one language to another through one or more learner or bilingual speaker; this speaker made an imperfect code-switch and was imitated by monoglot speakers of the receptor language.

But strikingly this particular wave did not stop there. Pre-aspiration is also found in the Scottish Gaelic of the Outer Isles (as in *cat* 'cat' /kʰaʰt/), presumably under the influence of Norse-speaking invaders in the Middle Ages. Yet pre-aspiration is not found in the Scottish Gaelic the Scottish mainland. However, pre-aspiration is a feature of the English of the Outer Isles (e.g., *white* /ʍʌiʰt/ *white*), even among monoglot English-speakers.

The conclusion is that the wave expansion of pre-aspiration has led to the convergence, in this respect, of mutually unintelligible languages in part of Northern Europe. Where the advance has halted, it has separated accents of speakers of Scottish Gaelic and accents of speakers of English. A wave expansion therefore leads both to convergence and divergence.

A similar wave is the spread of a uvular approximant or fricative in place of an earlier alveolar sound (trill, tap, or fricative). This began in Paris in the seventeenth or eighteenth century and subsequently spread through most of France. However, it also crossed language barriers and is now found among speakers of Dutch, German, Danish, Swedish, Norwegian, and even Italian and Icelandic. Interestingly, it came to characterize speakers in the Newcastle area, a part of the mainland of England

that faces the 'uvular' European mainland (though this pronunciation is now dying out as stigmatized).

An example of a grammatical wave-expansion is the loss of the Latin comparative form of the adjective in *-ior* (*altus* 'high,' *altior* 'higher'). This was at first replaced with a phrase consisting of the adverb *magis* 'more' followed by the adjective, e.g., *magis altus*; subsequently, in the center of the Romance area a change to a similar construction with *plus* 'more' spread out, e.g., *plus altus*. The result is that Italian and French have *più alto* and *plus haut*, respectively, while on the periphery one finds Portuguese *mais alto*, Spanish *más alto*, and Romanian *mai înalt*.

3. Indo-European Areal Features

The phenomenon of wave-expansion can, it is claimed, shed light on certain problems in historical linguistics. For example, wave-expansion suggests an explanation of similarities between different branches of the Indo-European (I-E) family which are or were in geographical proximity. In this case the varieties, though genetically related, are (in their latest attested forms) not mutually intelligible (see Bloomfield 1933: 314–6).

   (a) Somewhere to the east of the center of the I-E family a change occurred by which a velar [k] or palatal [c] plosive became fronted to an alveolar [s] or palato-alveolar fricative [ʃ]. The languages affected are the Indo-Iranian and Balto-Slavic groups, Albanian and Armenian. These are known as the *satem* languages (from Avestan/ satəm/ 'hundred'). Languages which retained the velar (or subsequently changed it to [h]) are known as the *centum* languages (Latin *centum*/kentum/'hundred'). These are the Italic and Germanic groups, Greek, Hittite, and Tocharian, situated to the west of the area and on the southern and eastern periphery.

   (b) In Greek, Armenian, and Indo-Iranian certain past tenses are formed with a vocalic prefix (an 'augment').

   (c) In Celtic, Latin, Hittite, and Tocharian, a passive is formed with a suffix including the letter *r* (the 'passive in *-r*') as in Latin *necatur* 'he is being killed'). These languages are on the periphery, and this fact, together with a related form in *-r* in Indo-Iranian (though not with a passive meaning), leads us to conjecture that the center of the I-E area introduced alternative means of expressing the passive voice.

   (d) Germanic and Balto-Slavic languages have certain case-endings not found in other I-E languages.

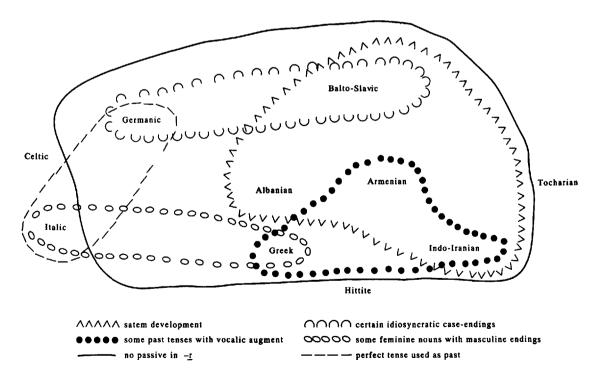
   (e) Italic languages and Greek show the idiosyncratic feature that certain feminine nouns have masculine endings.


Figure 1. Some areal features of the Indo-European family (adapted from Bloomfield 1933: 316).

(f) Italic and Germanic began to use a perfect tense as a nonperfect past (though the modern Romance and Germanic languages subsequently developed a periphrastic perfect).

Figure 1 shows how these various wave-expansions intersected. This model allows one to plot similarities and differences that cannot be captured in a family-tree analogy.

4. Explanation of Wave-changes

Wave-expansions are characterized by the spread of an innovation and, in some cases, by the cessation of the spread. These phenomena are in reality the result of the behavior of individual speakers and such behavior is, to some extent, explicable. Explanations may be sought from sociolinguistic observations and from social history.

Where a change moves from one variety of language to a mutually unintelligible one, it is as the result of imperfect code-switching on the part of one or more speakers. The question then arises why this innovation is copied.

In the first place, the individuals in a community sharing a language will be liable to make the same transfers, via imperfect code-switching, from this language to a new language. The result will be a mutual reinforcement of such transfers. These transfers may in fact become markers of group solidarity (see *Speech Accommodation*). This would explain the appearance of pre-aspiration in bilingual speakers of English (see Sect. 2 above), thus continuing the southern expansion of this cross-language phenomenon. It can even be the case that a community gradually loses a language; successive generations will show increasingly less proficiency in the old language (the substratum) and increasingly greater in the new prestige one (see *Language Maintenance, Shift, and Death*). In a final stage, children learn only the new language from bilingual parents and so as monoglots acquire substratum features.

Where the substratum shows regional variation, this will be reflected in the acquired language. For this reason, English as spoken by bilingual and monoglot speakers in the Gaelic-speaking area of the Scottish mainland does not have pre-aspiration. The result is a geographical division characterizing both Scottish Gaelic and English, mutually unintelligible languages.

But wave-expansions also occur in an area where there was previously a more or less homogeneous language variety. In such cases, an innovation (however it comes about) may be imitated because the original innovator was regarded as a desirable model. The imitation is then copied as something fashionable or a marker of group-solidarity. Since before the advent of mass literacy and of radio, communication was necessarily in face-to-face interaction, such imitation inevitably spread geographically.

A wave movement may stop because of geographical factors—rivers or mountains—which inhibit communication. There may also be political boundaries. Bloomfield (1933: 343–44) gives five instances of obsolete political boundaries which coincide with isoglosses of northern German dialects. There may be other, less obvious reasons. Labov (1972; Chap. 1) gives an account of a very localized sound-change in American English: his suggested explanation is that this is in order to accentuate the difference between natives of an area (Martha's Vineyard), marked by the innovatory sound, and visitors or incomers (see *Sociolinguistic Variation*).

5. Irregular Advance of Wave-movements

However, the word *wave* as applied to linguistic phenomena is a metaphor and, as often happens, the metaphor itself may mislead. The impression gained, and reinforced by simple maps, is that wave-expansions advance in a continuous line. But since the phenomena described as wave-expansions are aspects of speech behavior on the part of individuals, the spread may occur in rather more complex ways. Social factors play a part. Changes may 'leap' from town to town, ignoring intervening rural areas, not unexpectedly given such things as trade-routes and patterns of travel. Age too may play a part, younger speakers may be more likely to adopt new ways.

For example, it was stated in Sect. 2 above that the uvular realization of /r/ was found among speakers of German. This does not mean that all speakers of German use this sound and a map which attempted to show the actual situation would be impossible to draw. Three tendencies seem to be in play: the uvular realization is used more by young speakers, by urban speakers, and by speakers from the north of the German-speaking area; the alveolar realization is used more by older, rural speakers from the south.

The social connotations of individual words may even play a role in disrupting the continuity of a wave-movement. In most Dutch dialects the words for *house* and *mouse* have the same vowel (which may be one of four qualities); but in three areas *house* is /hy:s/ (an innovative vowel) but *mouse* is /mu:s/ (an earlier one). Since the Hollandish prestige vowel was /y:/ and since the word *house* would occur much oftener than *mouse* in official speech, the word *house* with the prestige vowel spread into districts which preserved the earlier vowel in *mouse*. (Bloomfield 1933: 330.) Here again a wave-change has proceeded erratically.

6. Sprachbund and Linguistic Area

The term *Sprachbund* (plural *Sprachbünde*) (literally 'language federation') was introduced by Trubetzkoy

and the term *linguistic area* by Emeneau (see *Emeneau, Murray Barnson*) to refer to a group of adjacent languages showing similarities of any of the types illustrated above and in consequence differences from their genetic relatives.

The Sprachbund known as the Balkan languages was perhaps the first to be recognized (by Schleicher). The principal languages in question are Albanian (A), Bulgarian (B) Greek (G), and Romanian (R). Though all Indo–European, they belong to different branches of that family.

(a) They are characterized by many loanwords from Turkish (T), some originally from Arabic or Persian. (For centuries, the Balkans were ruled by the Ottoman Empire and not surprisingly there is a strong Turkish influence on these languages.)

(b) In A and B, and to some extent in R, there are verbal forms which distinguish reports of attested actions (those witnessed by the speaker) from unattested ones, those that the speaker has heard about at second hand; this is a characteristic feature of T grammar.

(c) Morphologically, the genitive and dative cases are identical in A, B, G, and R.

(d) A future tense on a relic of a verb 'want' is found in Tosk (Southern) A, B, G, and R.

(e) A postpositioned definite article is found in A, B, and R (see above).

(f) The infinitive has been replaced by a finite clause, ('I want that I go' instead of 'I want to go') in B and G; this occurs to a lesser extent in A and R.

(g) The comparative of adjectives is formed analytically ('more short' rather than 'shorter') in A, B, G, and R, as it is in T.

(h) Noun phrases used as direct or indirect objects can or must be preceded by particles (originally preposition or pronoun) in A, B, G, and R. This, together with morphological indication of accusative, allows identification of the O in the frequent sentence order OVS.

Other Sprachbünde have been recognized in Amazonia, on the Baltic coast, in Ethiopia, in Central America, on the Northwest Coast of America, and in South Asia (see Masica 1976).

7. Problems in Areal Linguistics

It should be pointed out that, in the absence of documentary evidence, inferences of mutual influence in areal linguistics are drawn on the basis of probabilities. As more evidence, or other probabilities, are taken into account, then inferences may change. Above all, coincidence cannot be discounted.

7.1 The Validity of Assumed Wave-expansions

The assumption of wave-expansions must not be made lightly. Eastern Armenian contains a series of ejective consonants, not found in Western Armenian or other Indo-European languages. It was assumed that these had spread from the geographically contiguous Caucasian languages which are rich in such sounds. If, however, the plausibility of the 'glottalic' theory of Indo-European is accepted, then it is possible that Eastern Armenian has, alone among Indo-European languages, retained an archaic feature.

Similarly, it cannot be ruled out that some similarities are due to coincidence, perhaps on the basis of a universal human tendency. For example, many of the Romance languages show a satem-like development, in that certain Latin velar plosives have been fronted, resulting in dental, alveolar or palato-alveolar fricatives, or palato-alveolar affricates (Latin *centum* /kentum/, Spanish *cién* /θjen/, Portuguese *cem* /sẽĩ/, French *cent* /sã/, Italian *cento* /'tʃento/. Indeed this process has gone further in French than in the others (Latin *campus* 'field,' Portuguese *campo* /'kãpo/, Italian *campo* /'kampo/, French *champs* /ʃã/). But central dialects of Sardinian do not show this development. This change in the Romance languages could be regarded either as a wave-movement (beginning in French and encircling Sardinia) or as the result of a universal tendency, for a similar process is observable in many other languages, among them Old English, accents of modern Greek, Scandinavian languages, and Turkish. The latter is more plausible, for the precise details of the fronting in Romance vary: even within the French area we find medieval Picard /kaʃe/ against (modern) Standard French /ʃase/ *chasser* 'to hunt.' The possibility can therefore be entertained that in I-E there were various independent satem-developments and that Fig. 1 gives a false impression in this respect.

It could be suspected that phonological similarities may be more likely than grammatical ones to be due to coincidence. However, grammatical developments may also occur independently. While it may be the case that the Celtic languages aided the introduction of the progressive tenses (e.g., *I am going*) in English and that this can therefore be regarded as an areal feature characterizing a group of languages of the British Isles, the same device is found in modern Italian, Spanish and Portuguese (though not in French). This feature is presumably independent of the British Isles one. Since developments can occur independently in geographically separate areas, there is no reason why they may not occur independently in adjacent areas.

The use of a perfect tense as a nonperfect past, which was regarded in Sect. 3 as a wave-movement characterizing Italic and Germanic, is in fact typical of modern spoken French, northern Italian and some kinds of German. While this modern development itself may well be due to a wave-movement, the fact

remains that a development has repeated itself, in other words, occurred independently. That being so, it may be the case that the historical developments in Italic and Germanic were independent.

7.2 The Nature of Sprachbünde

It cannot be taken for granted that where a Sprachbund or linguistic area is recognized, the similarities are due to the spread of features in common from only one of the varieties, unless there is evidence for this. It may be the case that there are overlapping wave moments originating at different points.

Linguists have addressed the problem of whether or not the languages in such geographically similar groups should be genetically related or not. Trubetzkoy drew a distinction between 'language families' (*Sprachfamilien*) whose most important characteristic is regular correspondences between sounds and 'language federations' (*Sprachbünde*) which do not have regular sound correspondences, but which have been in geographical contact and show similarities in syntax and semantics. In a similar vein Emeneau defines a 'linguistic area' as 'an area which includes languages belonging to more than one family but showing traits in common which are found not to belong to the other members of (at least) one of the families.' Both definitions appear to exclude groupings of genetically related languages and hence would make it impossible to recognize a Balkan Sprachbund, since the languages in question are all I-E.

However, the essential point is that the similarities in question are not inherited but have spread geographically. Seen from this point of view, the process by which features spread within mutually intelligible varieties (the concern of dialect geography) is no different from that by which they cross from one variety to a mutually unintelligible one (the concern of areal linguistics). This condition is met by the Balkan group.

Sprachbünde are not discretely delimited any more than are dialects or languages (see *Language*). There may be more or less typical members of a given Sprachbund. Thus Serbo-Croat may be regarded as a fringe member of the Balkan group since it shows a Balkan type future tense; indeed nonstandard dialects of Serbo-Croat show a postpositioned definite article and other Balkan features. On the other hand, although Armenian has lost the distinction between genitive and dative it is not generally reckoned to be a member of the Balkan Sprachbund.

There are many instances of areal similarities where no Sprachbund is generally recognized. Examples were given in Sect. 1.2 above of similarities between English and contiguous languages. Hungarian (but not other Uralic languages) and German

have verbs with separable prefixes. Hungarian, Slovak, and Czech (but not other Slavic languages) have the palatal consonants [c] and [ɟ], long versus short vowels, and initial word stress. In all such instances influence of one language on the other(s) may be suspected but confirmatory evidence is essential.

It may be that there is a problem of delimiting the relevant geographical areas. It is said that there is an area running diagonally over northern Europe in which rounded front vowels (e.g., French *pur, peur*, German *Hüte, Söhne*) are found; the languages in question are Breton, French, Dutch, German, Danish, Norwegian, Swedish, and Finnish. These vowels are also found in adjacent northeast Italian dialects, e.g., that of Milan, but are absent from some southern German dialects. The resulting area is geographically continuous. Two problems arise. The first is that this alleged grouping is suspect for there are in fact two separated areas of southern German dialect (centered on Zürich and Vienna respectively) which do have rounded front vowels as well as one in the central German dialect area. Moreover, similar vowels are found in geographically adjacent Hungarian and in at least one dialect of Scots, spoken in a location (North Angus) which happens to face the northern European rounded front vowel area across the North Sea. How much of this should be regarded as a potential linguistic area? The second problem is the familiar one of the possibility of coincidence. The processes by which the French and German rounded front vowels have developed are intelligible without reference to each other or to any other language. Only if some geographical spread can be proved can coincidence be ruled out.

8. Envoi

In spite of problems in areal linguistics (and historical linguistics is not without its own problems), consideration of the effects of languages being spoken in adjacent territories is indispensable both in studying the histories of individual language varieties and in forming a general conception of how languages may change. In this connection, it should be remarked that once a feature acquired by language contact is established in a language, that feature is as liable to historical change as any other. It may therefore be the case that where adjacent language varieties show similarities, it may be virtually impossible to decide whether these are due to genetic relationship or cross-language borrowing. This can raise immense problems in language classification and lead to consequent differences of opinion between scholars.

Bilingualism and Language Acquisition
C. Letts

The issue of language development in the global majority of individuals who will grow up to be bi- or multilingual is often ignored in discussions of child language acquisition. This is especially so where mechanisms of acquisition and explanatory models are the focus of study. The justification for this would seem to be that bilingualism adds unwanted complexity to consideration of the data, and that bilingualism can only be addressed when a satisfactory model of monolingual acquisition has been developed. Studies of bilingual language acquisition have then tended to be descriptive in nature, and to have focused on issues such as sequence of development, separation of the language involved, and use and choice of languages.

Related issues include language use within the individual's wider community, and in particular within education. Political and cultural factors influence the perceived status of the child's languages, and the desirability of maintaining these languages. In addition, there has been considerable debate concerning the effect of bilingual language development on the child's cognitive and academic abilities.

1. Types of Bilingualism

Individuals commonly held to be bilingual (see *Bilingualism, Individual*) may vary considerably in their skills and use of their languages. This variation results from wide differences in particular linguistic situations, and also in the way in which bilingualism is acquired. Individuals become bilingual for a wide range of reasons; they may have parents who speak different native languages, they may live in a community where two languages have long been in use as a result of political and historical factors (e.g., Wales in the UK), they may live in diglossic societies, where language is selected according to social convention, or they (or their forebears) may have migrated from one linguistic community to another.

Within each of these situations, individuals will vary as to the time at which they are first exposed to each language, and the degree of exposure at any one stage of development.

While it can be argued that each bilingual individual is different, traditionally there has been a rather crude division into 'simultaneous' and 'sequential' bilingualism. These terms relate to the way in which bilingualism is acquired. With simultaneous acquisition the child is assumed to have more or less equal exposure to two languages from birth. Where acquisition is sequential, exposure to one language begins some time after the child has begun to acquire the other language (for convenience, these will be referred to as L2 and L1, respectively). For the sequential bilingual, L2 acquisition, generally assumed to occur naturalistically, may overlap with 'learning,' if the child experiences some formal teaching to help with his or her L2.

Bilingual individuals may also be grouped according to the degree of bilingualism they display in different sociolinguistic situations. Complete equal and native control of two languages is probably rather rarer than the skilled use of each language for particular situations, resulting in an individual who has appropriate linguistic skills for all social situations encountered (for example, students generally find it easiest to discuss a topic in the language that was used when they were first exposed to the subject area). At the other extreme, there are bilinguals who may use one of their languages only in very restricted circumstances, for example in the home and with older family members, and who may have no knowledge of its written form.

2. Bilingual Language Acquisition

2.1 Simultaneous Acquisition

The most usual situation in which two languages are acquired simultaneously, is where the parents each

have different native languages which they use with the child. There have been many diary-style studies of such children (for example, the study reported by Leopold 1939–49 was so careful and detailed that it became a seminal work on child language acquisition in general), so it has been possible to describe some overall stages in the acquisition process. One of the clearest accounts is given by Volterra and Taeschner (1978), who collected data from two sisters, acquiring Italian and German simultaneously. They describe three principal stages. At stage one, corresponding rather to the single-word stage in monolingual children, the child appears to be operating with only one lexical system (see *Child Language: An Overview*). Vocabulary is drawn from both languages, but only one word expresses one meaning; the child does not have a choice of lexical items for the same entity. At stage two, she appears to be operating with two lexical systems. She is now producing multiword utterances, but words in any one utterance tend to be selected from the same language. There is more confusion as regards syntax, however, the child tending to simplify and combine rules from both languages (the problem of the negative particle for example, which comes before the verb in Italian, but after the verb in German, was solved by one of the sisters by always placing it at the end of the sentence). More recent accounts, however, have suggested separate development of syntactic systems from the beginning (for example, De Houwer 1990).

The final stage is characterized by growing separation of the two languages, at both lexical and syntactic levels. A common feature of this stage is that the child rigidly associates particular languages with particular people, and may become distressed if adults do not conform to this. It is hypothesized that this rigid association helps the child to keep the two linguistic systems apart, at a time when they are rapidly developing in complexity. Awareness that there are two languages also develops around this time; before this stage is reached, the child will find requests to translate incomprehensible.

2.2 Sequential Acquisition

There are fewer studies of sequential bilingualism available, but generally it is thought that young children acquiring an L2 go through similar developmental stages to the monolingual child acquiring that same language. With older children, the developmental sequence may be influenced by formal second language teaching. There is growing evidence that L2 acquisition may be influenced by the child's personality, general approach to the problem, and particular language-learning strategies, just as it is in language-learning adults. Bates et al. (1988) provide a particularly striking example of a child who uses very different strategies to acquire a second language

(admittedly on the basis of very limited exposure), than she previously used to acquire her first language.

There has been much interest in the importance of age in determining a child's success in acquiring a second language. It is often thought that the young child acquires languages especially easily, with this ability declining as he or she approaches the end of the critical period (though when exactly this is, is controversial). However, there is some evidence that, while younger children are particularly adept at acquiring L2 phonology (segmental and nonsegmental), older teenaged children may be better at acquiring grammatical patterns.

2.3 Language Dominance and Attrition

Bilingual language acquisition does not occur in a vacuum, and it is unlikely that the bilingual child will have equal input from both languages at any one time. For any individual at a given point in time, one of his or her languages will be dominant, used in more situations than the other one, and used more skillfully. Any form of testing or assessment in the nondominant language will lead to a false picture of the child's overall language development.

It is also well documented that if input ceases for a language, knowledge of that language will quickly be lost by the child. This is known as language 'attrition.'

2.4 Transfer

A common source of interest regarding the bilingual child is the extent to which there is transfer from one language to the other. Transfer (once called 'interference') consists of elements of one language influencing an utterance that is mainly in the other language. Parents and educators may become alarmed when this happens, as they may feel it is an indication of confusion between the two languages (although this will be perfectly normal in the early stages of simultaneous acquisiton—see Sect. 2.1 above). However, transfer is common and well-tolerated in many bilingual communities, where speakers may switch rapidly with little awareness that they are doing so. Also common in bilingual communities is code-switching (see *Code-switching: Overview*), in which there is alternation between languages over longer stretches of discourse.

Anecdotal evidence suggests that, providing the two languages are kept separate in input (i.e., if speakers are consistent in which language they use with the child, and do not code-switch or show features of transfer themselves), the child is unlikely to show much evidence of transfer once the initial stages of language acquisition are passed. Fantini (1985) in his study of his Spanish–English bilingual son Mario, notes limited transfer at a number of linguistic levels. As regards phonology, Mario lacked control over some allophonic variants of English,

431

tending to deploy phonemes according to Spanish phonological rules. As regards syntax and morphology, transfer of morphemes and grammatical relations from one language to the other was noted and some effects on word-order. Loanwords were sometimes transferred from one to the other, and given appropriate morphological endings. Lexical borrowing tended to occur when he did not have an equivalent word (expressing the same meaning) in the other language. Fantini also notes some confusion of cultural norms of behavior (e.g., shaking hands or kissing), and some interference affecting conversational and discourse convention.

3. Effects of Bilingualism on Cognitive and Academic Development

In the past, being bilingual was felt by many monolinguals to be profoundly detrimental to a child's psychological, social, and cognitive development. Hence in Wales in the UK, for example, strenuous efforts were at one time made to stamp out the use of the nondominant language, Welsh, in schools. Such attitudes have long been discredited. Early experimental work that claimed to show the detrimental effects of bilingualism has been shown to have a number of serious methodological weaknesses, including testing in the child's less dominant language, ignorance of cultural differences that would influence the child's response to testing, and prejudice on the part of experimenters. More recent research suggests that bilingual children may have some cognitive advantages over their monolingual peers, developing metalinguistic awareness earlier, and displaying more flexibility in cognitive tasks. Baker (1988) presents an excellent discussion of these issues.

Continuing concern has been expressed, however, for the plight of some sequential bilinguals who are required to acquire an L2 rapidly upon commencing education, or following migration to a new country. Results of studies have been misleading. While some children cope well and have an enhanced quality of life and experience as a result of their bilingualism, other groups fail consistently to do well in school. The research centers around the work of Cummins (see *Cummins, Jim*) and colleagues in Canada who set up and evaluated the highly successful 'immersion'

programs for English-speaking school entrants acquiring French (see, for example, Cummins and Swain 1986). These children, who were taught by bilingual teachers entirely through the medium of French for the first two years, did well. The conclusion was that this success resulted from careful planning, teachers who understood and accepted English from the child, and the fact that French was a new language for all the children.

Less fortunate children who have to acquire an L2 rapidly in a sink-or-swim context may give the appearance of competence in L2 in day-to-day conversation. However, it is suggested that they may fail to acquire more academic (and less contextualized) language in the early days of formal education when this may be crucial for later academic development. They are still at this stage inexpert in the L2, and do not have opportunities to develop this style of language use in L1, since it is not used in school. These findings remain controversial, but the implications are that carefully planned introduction of the L2, and/or mothertongue programs so that use of the L1 can be maintained and extended into new areas, are desirable. Good bilingual education can then become a positive asset.

Borrowing

J. Heath

A 'borrowing' is a form that has spread from one linguistic variety (the 'source') into another variety (the 'target' or 'replica'). In this sense it is nearly synonymous with 'loanword,' but a borrowing is

often really a stem (smaller than a word), and may be a phrase (larger than a word). Borrowing is also the term for the act of incorporation itself, so there is a certain semantic ambiguity between process and

result in the usage of the term. Although the focus here is on language-to-language transfer (see *Language Transfer and Substrates*), the concept may also be used when discussing the spread of a form among mutually intelligible dialects of a single language, or even among registers or idiolects (see *Register*).

The close analysis of borrowings involves many aspects of linguistic structure—particularly phonetics/phonology, morphology, and lexical semantics. The study of borrowings is of interest to general linguistics because the borrowing language may have several possible ways of incorporating the foreign form into its own phonological, morphological, and semantic systems, and the options implemented may reveal something about deep-seated developmental tendencies of the language that are not otherwise clearly evident. But the study of borrowings cannot rely entirely on considerations of pure linguistic structure, however 'deep.' Rather, borrowing patterns also reflect the social and historical context in which the language contact takes place. For this reason, borrowings play an important role in historical linguistics and sociolinguistics.

1. Basic Concepts and Terminology

1.1 Borrowing versus Code-switching

The term 'borrowing' is semantically misleading from the start, since it implies that the source language relinquishes a form in lending it temporarily to the target language, which is expected to return the form later (with or without interest). It is a historical quirk that the term 'borrowing' is used instead of spreading, imitation, proliferation, cloning, or mitosis. However, there is a more substantive terminological difficulty due to the sometimes fuzzy boundaries between borrowing and code-switching.

In extreme cases, the difference between borrowing and code-switching (see *Code-switching: Overview*) is clear. The word 'money' is a thirteenth-century borrowing from French, but few modern speakers of English would be aware of its foreign origin. At the other extreme, a pair of bilingual speakers might converse for a while in pure English, then shift abruptly into French for a ten-minute stretch—because French seems more appropriate to a new topic, because they do not want an eavesdropping English monolingual to overhear them, or for some other reason. In other words, a borrowing is (ideally) a historically transferred form, usually a word (or lexical stem), that has settled comfortably into the target language, while code-switching is (ideally) a spontaneous, clearly bounded switch from sentences of one language to sentences of another, affecting all levels of linguistic structure simultaneously.

However, if actual speech patterns in bilingual environments are observed, one finds that borrowing and code-switching are not always so clearly distinct.

For one thing, many borrowings are only partially nativized into the target language, and even monolingual speakers may be conscious of their foreign status. Second, widely used (hence presumably borrowed) forms may have a degree of internal phrase structure that speakers are (to varying degrees) aware of, as when French *femme fatale* or Latin *quid pro quo* is used in English. Coming from the other direction, spontaneous mixing of material from two languages most often takes the form of incorporating phrases or words from a foreign language into slots in a clearly primary base language, rather than abrupt shifts from entire sentences of one language to those of another. In other words, borrowings may resemble code-switches in retaining a foreign status and/or a discernible internal structure, while code-switches often resemble borrowings in brevity (words, short phrases) and in being fitted into another language's syntax.

To deal with such problems, some scholars have expanded the terminology by adding a third term such as 'code-mixing' to cover certain intermediate cases such as phrasal code-switching. Still further terms are needed for special cases, such as 'loanblend' for combinations of a borrowed and native element, like the German *altfäschen* 'old-fashioned' (containing German *alt* 'old'). However, the basic difficulty is not the lack of labels—which could easily be multiplied further—but the intrinsically gradient and fuzzy nature of the continuum, and it is perhaps best to keep the terminology simple while remaining aware of its limitations.

An additional problem in using degree of nativization to distinguish borrowings from code-switches is that nativization may be more advanced on one linguistic level than another. For example, the phonological segments of the foreign form may be closely adhered to, as when an English speaker carefully replicates the voiceless *u* of the Japanese borrowing *sukiyaki*, but the prosody (stress, intonation, etc.) may be entirely native. In a case like *formulae* [formjəli ~ formjəlay], some English speakers make a point of retaining the Latin (nominative) plural suffix, even if occasionally mispronounced, but the phonology of the stem is adapted to English, as seen especially in the intrusive [j] before original *$\bar{u}$. On the other hand, there are cases like (plural) *femmes fatales* [fam fatal-z], where an English speaker can pronounce the final *s* [z] as the (English) plural marker, while carefully retaining the segmental pronunciation and even prosody of the French noun phrase. In general, a form may behave like a nativized borrowing on one level, and like a spontaneous code-switch on another. Even on a single level, the extent of nativization of various segments may be inconsistent. In some cases, moreover, whether nativization has occurred is moot, as when a string of

segments in a foreign form happens to require no phonetic adjustment in the target language, or when (say) a plural ending happens to be shared by the two languages.

1.2 Borrowing versus Transfer

'Borrowing' requires an actual copying of forms (stems, morphemes, words, phrases). 'Transfer' (also called 'interference') is a more subtle result of language contact, whereby inherited forms already in the target language are adjusted in some way under the influence of one or more source languages. If the source language producing the interference is spoken by a dominated group within the speech community, it is called a 'substratum' language (frequently a substratum dies out after a few generations, leaving its imprint on the surviving language); if the source is a neighboring language it is called an 'adstratum.' Mutual interference may be called 'convergence,' and regions containing three or more languages that have converged extensively over a long period of time are called *Sprachbünde* (singular *Sprachbund*), using a German word meaning 'language-association.' Typological convergence among dozens or hundreds of languages in a major region (USA, Southern Asia) is the focus of 'areal linguistics' (see *Areal Linguistics*), which provides tantalizing maps of trait distribution (without usually being able to trace the myriad of individual historical shifts that produced it).

The most obvious kind of transfer is what is popularly referred to as a 'foreign accent,' consisting of several segmental and prosodic features carried over from the source (substratum) into the target language. Under favorable sociohistorical conditions, an initially foreign accent may become established over time as the norm for the speech community. Language families that result from sudden expansion due to rapid military conquests tend to be highly divergent phonetically (and phonologically) because at least the outlying languages strongly reflect pronunciation patterns of various foreign languages (perhaps subsequently lost). This is a major reason why French (with Celtic and Germanic substrata) and Romanian (in a *Sprachbund* with an important South Slavic element) seem so different from each other and from Latin, while Italian (particularly as spoken in Tuscany and Rome) retains much of Latin phonetics and prosody. Going back further in time, the rapid expansion of ancient Indo–European languages from their original homeland into western and southern Europe, the Indian subcontinent, and other distant areas is reflected in the radically different phonologies of languages like Old Irish, Old Norse, Latin, Greek, Albanian, Sanskrit, and Tocharian, which makes recognition of cognates difficult. Another major case of rapid expansion was the Arab conquest of (Berber and Coptic) North Africa, Persia, and the Aramaic-speaking Levant.

Transfer is also important in morphology and syntax. While some actual borrowing of affixes can take place (see Sect. 2.5), the more common pattern in a *Sprachbund* or stable bilingual zone is some borrowing of mutual convergence in the semantics and pragmatics of grammatical categories, with little or on actual borrowing of affixes. For example, Basque (a non-Indo–European isolate) has now cohabited with the Romance languages Spanish and French for nearly two millennia, and it is no accident that Basque has a system of grammatical categories (including perfective/imperfective aspect, a subjunctive mood, and an infinitive) that resembles those of its neighbors. However, the actual affixes are native Basque forms (with one or two interesting exceptions), and there is little sign of convergence in such formal details as the order of stems and morphemes within the verb or noun.

Morphosyntactic interference is usually gradual, involving many slight rearrangements of native structures, and for this reason it is particularly difficult to distinguish ordinary, language-internal historical change from change due to external interference. In fact, to the extent that each language is a well-integrated grammatical system (a point emphasized by many typologists and functionalists), a sharp distinction between internal and external causation is impossible to make. For one thing, the target language is inevitably selective in undergoing only a subset of the theoretically possible morphosyntactic pattern transfers favored by contact with the source language. For another, any significant change in one component of the target language (e.g., due to external interference) is likely to have an immediate ripple effect, by which other components are adjusted formally or functionally to jibe with or to compensate for the initial change. In actual historical linguistic practice, successful analyses of morphosyntactic change generally consider complexes of external and internal factors simultaneously.

Long-term bilingualism also favors significant semantic convergence in the lexicon, in addition to actual borrowings. John Gumperz and Robert Wilson have claimed that the three languages spoken in Kupwar, a town in India, have converged to the point of virtually complete grammatical and lexical interanslatability. One form of lexical convergence is the 'calque': the recreation, using native material, of a compound or phrase from another language. English 'skyscraper' is copied by German *Wolkenkratzer* ('cloud-scraper'), French *gratte-ciel* ('scrape-sky'), and other European equivalents. English speakers learning another modern European language may fumble a few lexical distinctions, but thanks to an accumulation of calques and other

lexical convergences they can count on finding translation equivalents for such words as *yes* and *thank you*, and in general do not have to enter a new thought world. They are not so lucky when learning Navajo or Warlpiri, and even Latin poses problems ('yes' is a diffused innovation absent in ancient Indo–European languages, as Antoine Meillet pointed out in 1925).

2. Borrowing Mechanics

In some cases, borrowing a stem presents no special phonetic, phonological, or morphological difficulties. If the stem is the source language happens to consist of segments, syllabic combinations, and a prosodic (e.g., stress) pattern that are already quite normal within the target language, no phonetic adjustment is necessary. This presumably facilitates borrowing between closely related languages, not to mention dialects of the same language. If, in addition, the relevant word class in both languages has a high-frequency form (e.g., the nominative singular of nouns) that lacks affixes, the stem can readily be borrowed in this morphologically bare form, and can then be fed into the regular derivational and inflectional system of the target language in order to create whatever morphologically marked forms (plural, dative, etc.) are needed.

However, in almost all cases of borrowing across language boundaries, at least some of the borrowings require phonological adjustment. Moreover, the target and/or source languages may have inflectional systems that make it impossible to transfer stems in unaffixed form. Insofar as the pronunciation and/or morphology of the source form are clearly nonnative to the target language, choices among several alternatives have to be made.

2.1 Phonological Adaptation of Stems

The first variable is whether the aberrant source form is adjusted to fit the new phonological system, or retains much of its original pronunciation even as it becomes common in the target language. The French borrowing *déjà vu* occurs in a variety of pronunciations in English, ranging from [deʒɑ vy] through [deʒɑ vuw] to [deʒɑ vjuw]. Here the second variant changes the aberrant front rounded vowel [y] to a more native English vowel (long or tense /u/, realized as [uw]); the third form proceeds to insert [j] between a consonant and this vowel, as in many other English words, so that *vu* is pronounced like *view*. Clearly the extent of the speaker's (and the community's) bilingualism, and various situational factors, play a role in such variation.

In addition to the degree of nativization, choices must be made among two or more possible ways to nativize the source forms. A foreign phoneme (i.e., a cluster of phonological features) that has no exact equivalent in the target language is likely to be equidistant from two or more target phonemes each differing from it in one feature. For example, French high front rounded [y] in *vu* is nativized into English as high back rounded [uw], but there is no obvious reason why it could not have been borrowed with a high front unrounded vowel as *[vij], both changes involving adjustment of one phonological feature.

It is also necessary to consider suprasegmental aspects of nativization into a target language. Not only does each language have characteristic prosodic patterns (stress alternations, pitch-accent, tone contours, or whatever), but these prosodies often interact closely with segmental phonology. The most significant recent revisions of phonological theory have involved the recognition of previously unsuspected syllabic and rhythmical bases for many phonological phenomena. Thus, English stems borrowed into Japanese must be supplied with a pitch-accent pattern, while multisyllabic Japanese stems entering English must be adapted to the target language's system of alternating stressed and unstressed syllables, as in *sukiyaki* pronounced ['suki,yaki] or ['suwki,yæki].

Somewhat similar problems arise when the target (but not source) language is characterized by vowel-harmony patterns (as in Turkish, borrowing from Arabic, Persian, or English), or by rigid canonical-shape restrictions on stems (Arabic, borrowing from European languages). Interesting problems also arise when the source or target language is rich in consonantal but weak in vocalic distinctions, while the opposite prevails in the other language.

2.2 Spelling Pronunciations

Because literacy, including multilingual literacy, is now so pervasive, it is almost impossible to understand the phonology of recent borrowing in some regions (notably Europe) without recognizing the mediating role of spelling. Of course, this can hardly be avoided in borrowings from defunct languages, such as newly coined Latinisms, but the issue is also important in connection with living languages. The most obvious demonstration of orthographic interference is the frequent pronunciation of 'silent' letters in borrowed forms, corresponding to zero in the actual source form. Thus, standard dialects of Spanish (both continental and Latin) long ago ceased to pronounce initial *h*, but it is often revived in borrowings into English such as *hacienda*.

However, there are probably many other cases where a phonological adaptation, though of a type not incompatible with oral transmission, may have been influenced by orthography. In the case of (*déjà*) *vu* discussed above (Sect. 2.1), the consistent avoidance of front unrounded *[iy] in favor of back rounded [uw] in nativized pronunciations may have been subtly favored by the orthography (as well as by

435

other factors including the pre-existing English stem *view*).

Even when the source and target languages have entirely different scripts, the transcription of source forms in the written form of the target language may result in pronunciation differing from what one would expect from oral transmission. For example, the transcription of *sukiyaki* in restaurant menus may well have played a role in pointing toward English pronunciations like ['suwki,yæki]. Had the transmission been entirely oral, the voiceless *u* would very likely have been missed by English speakers, resulting in a pronunciation beginning with *[ski...]. Of course, to the extent that orthographies (which often omit prosodic information) mediate borrowing, the earlier comment about the relevance of source-language prosody must be reconsidered.

Orthographic complications are substantially absent in borrowings that take place in many intertribal, colonial, immigrant, and native-minority contexts, where literacy in the target and/or source languages is low. There are also some contexts where literacy in both languages is fairly high, but where sharp differences in scripts, or puristic avoidance of loanwords in written language, effectively eliminate literacy as a factor in borrowings. One example is European (French, Spanish, Italian, English) borrowings into North African Arabic, which are rarely mediated by written languages. Here, for example, the French high front rounded [y] is often converted into *i* rather than *u*; French *bureau* [byʁo] is borrowed as [biru].

2.3 Relexification and Hybrid Borrowings

'Relexification' occurs when vocabulary from one source language is largely replaced by vocabulary from a successor source language. This happens in pidgins and creoles (see *Pidgins and Creoles: An Overview*), but can also apply to borrowed lexicon in less traumatic circumstances. Examples are Third World countries that have been under the successive political and cultural influence of different European powers. In Morocco, Spanish was the first dominant European influence (on the coasts), to be followed by a more thorough domination by French, while English has increased in popularity. In the Philippines, Spanish was the long-term colonial language, but English has completely replaced it under American influence. Former German, Portuguese, Italian, and Dutch colonies or zones of influence (e.g., Tanzania, Angola, Somalia, Indonesia) are in various stages of transition, usually toward English as a sort of neocolonial language.

Because the successor source language has many cognates with the previous source language, 'hybrid borrowings' result. For example, Moroccan Arabic initially borrowed Spanish *interés* as *intiris* '(bank) interest,' but most Moroccans know the word in the

form *antiris*. The first syllable has been changed under the influence of French *intérêt*, the middle syllable is neutral, and the final syllable unmistakably continues the original Spanish borrowing. (For a different type of multiple-source contamination, see Sect. 3.2.)

In many other cases, there is no such residue of the earlier borrowing, which has simply been replaced by a new borrowing from the successor source language. However, when the earlier and later borrowings are similar in form (as when they come from cognates in the two European languages), one may suspect that the historical process was not so much a second borrowing as a kind of updating of the old borrowing, like the partial updating seen in the hybrids.

2.4 Morphological Adaptation of Borrowings

It is true that some borrowed forms are strikingly impervious to visible morphological embellishment in target languages. Thus, a number of borrowings from Berber or other languages into Moroccan Arabic refuse to take the normal definite prefix *l-*, hence *bəllarž* 'stork(s)' or 'the stork(s),' *atay* 'tea' or 'the tea'; contrast native *kəlb* 'dog,' *l-kəlb* 'the dog.' Similarly, some English speakers are uncomfortable with adding the English plural [−z] to weakly assimilated French borrowings like *bête noire*, *éminence grise*, or *femme fatale* (while other speakers have no such compunctions).

In extreme cases, a borrowing may be sufficiently inert or unstable morphologically in the target language to make its word-class status indeterminate. In Moroccan Arabic, the borrowing *himri* 'hungry, hunger' (a fairly old loan from Andalusian Spanish *hambre* 'hunger,' but secondarily associated with English *hungry*) is used indiscriminately as a noun or adjective in a manner not characteristic of native lexical items. A related situation is exemplified by German *Gesundheit* 'health,' which occurs in English only as an exclamation after someone else sneezes. Such examples might be said to constitute a minor, pidgin-like lexical stratum in the target language.

However, in most cases a borrowed noun or verb stem eventually acquires the normal set of inflectional and derivational possibilities of its word class. When both languages are highly inflected, as is often the case at least for verbal morphology, it is no simple task to decide how a stem from one language is to be transferred to the other. Indeed, target languages often resort to stratagems that evade the problem, for example, by borrowing verbs in an infinitive or other relatively simple form and adding a native verb like 'be' or 'do' in auxiliary function, or adding a 'thematizing' derivational affix between the borrowed root and regular target-language affixes.

The auxiliary structure is typical of borrowings from Arabic into Turkish. For example, instead of

attempting to find an inflected form of the Literary Arabic verb 'to thank' (perfective stem *šakar-* with pronominal suffix, or imperfective *-škur-* with pronominal prefix and suffix) that could be directly borrowed, Turkish took an Arabic verbal noun *tašakkur* 'thanking,' combined it with the native Turkish verb *etmek* 'do' (used here as an auxiliary), and produced the verb phrase *teşekkür etmek* 'to thank.'

An example of a thematizing affix is German *-ieren*, which is used heavily in verb borrowings, particularly from Latin and French: *finanzieren*, *diktieren*, etc. Similarly, Mexicano (Nahuatl) has thematizers such as *-oa* for borrowing Spanish verbs: *costar-oa* 'to cost' (Spanish infinitive *costar*).

2.5 Borrowing of Grammatical Morphemes

Linguists have sometimes argued that while lexical stems are readily borrowed, the morphosyntactic systems of each language are so tightly structured, and so far below the level of consciousness, that they do not permit direct borrowing of affixes and other bound forms from other languages except in peripheral cases. However, it is known that borrowing of bound morphemes is less rare than previously thought.

To begin with, it turns out that subordinating or conjoining particles ('because ... ,' '(so) that ... ,' etc.) are rather easily borrowed in some contexts, including colonial or postcolonial zones where native languages have borrowed heavily from an overlain European language. Such particles are mechanically rather easy to integrate into the target language, since they typically occur at the beginning or end of the clause and can therefore be appended to the periphery of what is otherwise an intact clause in the target language. For example, younger speakers of many languages spoken in Francophone West Africa (Senegal, Mali, Burkina Faso, etc.) routinely use French *mais* 'but,' *parce que* 'because' (locally pronounced [paskə]), *pour que* 'so that,' *à moins que* 'unless,' and similar clause-introducers, so that their complex grammar is at least superficially quite different from that of their grandparents. Hill and Hill (1986) report that many Spanish connectives and other particles like *pero* 'but,' *para* 'in order to,' and *porque* 'because' are common in modern Mexicano (Nahuatl).

However, the introduction of a foreign affix into target-language word morphology is more problematic. Sometimes a source-language plural (or definite) affix acquires a precarious foothold in the target language when unaffixed/affixed pairs are borrowed, as in English *formula*, plural *formulae* from Latin, or Moroccan Arabic *pisin*, definite *lapisin* '(the) swimming pool' from French (*la*) *piscine*. When such affixes occur also with nonborrowed stems, the question arises whether the affix was directly borrowed as such, or whether it was secondarily isolated by target-language speakers after digesting a number of such paired borrowings. For example, the minor English suffix *-ette* (from French) is used with non-French stems, not always in the original diminutive sense (*kitchenette, majorette*). However, it is difficult to describe the formative process in question as direct affix borrowing. Rather, English may simply have had a sufficient stock of double borrowings from French, like *cigar* and *cigarette*, to permit monolingual English speakers to recognize *-ette* as a derivational ending and to extend it (sporadically) to new combinations. When the source language has many lexical doublets involving a high-visibility derivational ending such as *-ette*, by the time the target language has absorbed a few hundred borrowed stems its native speakers are likely to segment the affix and may then expand its usage.

More difficult to borrow are true inflectional affixes, such as pronominal-agreement or tense/aspect/mood affixes on verbs, and case affixes on nouns, but a number of cases have been known for some time and many others have been reported. In one Romanian dialect, certain pronominal endings on verbs have been altered under Bulgarian influence: **aflu* 'I find' became *aflum*, and **afli* 'you find' became *afliš* (the local Bulgarian endings are *-am*, *-iš*). In 1953, Uriel Weinreich explained this in terms of the sheer productivity of the relevant Bulgarian paradigm, which helped it 'overflow' into Romanian, but also in terms of the pre-existing 'congruence in structure' of verbal paradigms in the two languages. Later theory tends to emphasize two points: (a) the initial phonological similarity between Romanian *-i* and Bulgarian *-iš* as a kind of phonological catalyst, and (b) the increased phonological distinctiveness of the resulting paradigmatic endings. While factor (a) helps make the crosslinguistic morpheme association possible, (b) is more teleological, suggesting 'formal renewal' of a categorial distinction (threatened with neutralization due to phonetic erosion) as a therapeutic or functional basis for this type of borrowing.

One may conjecture that borrowings like this Romanian one take place in communities with heavy long-term bilingualism, resulting in frequent sentence-internal code-switching whereby Bulgarian words and phrases are inserted into Romanian sentence frames, leading to a certain blurring of the boundary between code-switches and borrowings.

3. Borrowing Routines

3.1 Historical Development of Routines

Studies of twentieth-century borrowing patterns, particularly in (ex-)colonies with a dominant European language, suggest that relatively streamlined 'routines' for instant borrowing of foreign stems

(including verbs) are developed over decades or centuries, after an early period of more sporadic and uneven borrowing. Because some early-period borrowings become stable lexical items in the target language, at later stages it is possible to recognize them as an archaic 'borrowing stratum,' distinct in type from the wave of later and incoming borrowings (including on-the-spot adaptations) that obey the existing productive routines.

As noted in Sect. 2.4 the principal routine for nativizing European verbs into Moroccan Arabic is to borrow the Spanish infinitive form in *-ar* (*-er*, *-ir*) as the Moroccan stem, and to borrow a composite of French forms (differing from one French conjugation to another) characterized by a final front vowel as the Moroccan imperfective stem. However, examination of early colonial borrowings that have survived, and the direct testimony of colonial-period publications, show that these routines were not automatic in the earlier periods. Some early borrowings appear to have been based on shorter source forms (vowel-final forms in *-a* or *-e* for Spanish, and consonant-final unsuffixed forms for French). Thus French *déserter* 'to desert (from army),' a familiar military term in the colonial period, is recorded in Moroccan as *zṛti* or *zṛt*, showing reduction of French vowels to fit typical Moroccan verb shapes, and fluctuation between vowel- and consonant-final form; if it were to be (re-)borrowed using existing borrowing routines, it would take the form **dizirt*, retaining the original syllabic structure and ending obligatorily in *i*.

Routines develop when a particular pattern of source/target phonological and morphological correspondences—not necessarily dominant in the earliest borrowing stratum—succeeds in becoming the productive method for incorporating new borrowings. A fully streamlined routine, which may emerge only after decades of community bilingualism, permits instant borrowing (e.g., application of target-language affixes) of any source-language form of the appropriate word- or conjugation-class. Routines permit Moroccans who know French to toss off forms like *ma ta-y-t-ʔytilizi-w-š* 'it is not used,' where the very un-Arabic-looking French verb *utiliser* 'use' is flanked by strings of Moroccan Arabic affixes and particles to create a sentence nucleus.

3.2 Relexification and False Routines

In Sect. 2.3, it was pointed out that a borrowed stem may be a hybrid, by which an early borrowing from one source language was later partially (e.g., in its first syllable) reshaped under the influence of a cognate from a new source language. However, there is also another type of hybridization found in these contexts in which routines play an important role.

When one European language gives place to another as the source of new borrowings for a native language in this situation, old borrowings from the

first source language are secondarily associated with cognate forms in the successor source language. A Filipino, speaking Cebuano and English (but not Spanish), will notice many apparent English–Cebuano verb correspondences such as *cultivate/kultibar* and *complicate/kumplikar*. Of course, the Cebuano forms are historically from Spanish *-ar* infinitives *cultivar* and *complicar* but, with the near-disappearance of Spanish as a second language in the Philippines, English/Cebuano bilinguals conceptualize the correspondences as a routine 'add *-ar* to the English verb.' This results in occasional pseudo-Spanish forms like Cebuano *kumplinar* 'complain' which can only be based on English (cf. the unrelated Spanish synonym *quejarse* 'complain'). In Morocco too, *-ar* (modeled on early Spanish borrowings) is recorded in a few French borrowings like *siñar* 'to sign' (the Spanish synonym is *firmar*), and stem-final *-i* (typical of true French borrowings) is to be found in the first verb borrowings from English such as (slang) *spiki* 'speak (English).'

Some of these 'false routines' produce only a handful of forms and then sputter out, giving way to emerging routines better adapted to the new source language. The Moroccan form *siñar* has been largely replaced by (or update as) *siñi, sini,* or *sni*.

4. Borrowing in Social and Historical Context

4.1 Official Languages

In the modern world, much borrowing into standard languages is mediated by multilingual literacy and may be literally controlled or monitored by official organizations or committees. Scientific and other academic terminology, for example, typically takes the form of *neologisms* coined from Latin or Greek compounds. These terms pass easily from English to French to Spanish, or vice versa in any direction—the suffixes are adjusted to the local language by well-oiled routines, the orthography of the stem is otherwise largely retained, and local spelling pronunciations emerge. It is debatable whether these international words can even be called borrowings—the original compounds may never have existed in Classical Latin or Greek, and it is often unclear whether one modern language X has borrowed the terms from a particular other modern language or has simultaneously (re-)created the classical neologism using its own Latin-to-X routines.

The role of advertising and (other) propaganda also deserves a mention. At the time of writing, the world had been bombarded with *perestroika* and *glasnost*, Russian terms that have become synonymous with administrative reforms in the former Soviet Union. Television audiences in the USA have likewise been saturated with commercials from Volkswagen emphasizing the word *Fahrvergnügen* 'pleasure of driving (or traveling).' By virtue of their

novelty and foreignness, such terms combine a (theoretically translatable) general meaning with a precise, almost proprietary association to a particular government or corporation.

For a very different aspect of the role of official institutions in borrowing, see Sect. 4.7, Purism.

4.2 Colonial (and Postcolonial) Contexts

For the purposes of this article, the label 'colonial' is applied to any system in which the large majority of natives are politically, economically, and/or culturally subordinated to one of the world's hegemonic powers. This applies to some so-called 'protectorates' (e.g., Morocco), 'administered territories' (e.g., Puerto Rico), 'zones of influence' (e.g., Palestine), and annexed lands treated as provinces (e.g., Algeria), as well as to nominal 'colonies.' Moreover, most independent former colonies are included, as they have usually become more dependent culturally on the former colonial power than during the colonial period itself because of the huge postcolonial expansion of formal education, literacy, and broadcast media.

The extent of borrowing from colonial to native languages depends, to begin with, on the length of time involved and on the extent of actual colonial penetration. Some coastal regions were of interest to the colonial power essentially because of a port or to protect a sea lane; other colonies were valued as buffers against other hegemonic powers. Still others, like India and Algeria, were intensively colonized— settlers were brought from the home country to exploit local agricultural or other resources, modern European quarters arose beside native towns, natives worked for Europeans as laborers and domestics, and at least a small native elite was educated in European-type schools. With mass education, usually after independence, the colonial language took on a new importance, and the former power usually took pains to maintain its cultural (and hence political and economic) influence by sending teachers and textbooks, and by bringing native students and other visitors to the European country. In many parts of the Third World, the former colonial language is now an important vehicle for intertribal and regional communication (e.g., French and English in Africa).

If there is a consistent colonial language throughout this political sequence, one can expect a fairly standard 'life cycle' of borrowing patterns. At first, few natives speak more than a pidgin-like approximation to the colonial language, and colonial words are absorbed only painstakingly into the native (target) language, with significant phonetic distortion, morphological fusion or missegmentation, and speaker-to-speaker variation. Over several decades, at least partial bilingualism becomes widespread, a few hundred borrowings with recognizable connections to the colonial source form have become

established (so that models are available to establish source-to-target equivalences), and new borrowings more closely adhere to the pronunciation and exact sense of the source form. Sentence-internal code-switching has become common in the fluently bilingual segment of the native population, and the distinction between code-switching and borrowing begins to break down. Routines have been developed to borrow verbs as well as nouns, so that lexical stems can be spontaneously borrowed (i.e., inserted seamlessly into a native-language frame). Patterns of borrowing and code-switching diffuse to some extent throughout the native community, but there is always a sociolinguistically significant asymmetry between young and old, urban and rural, privileged and underclass.

The whole system is, of course, disrupted by a sudden replacement of one colonial language by another, as when German or Italian colonies and zones of influence were reallocated after World War II. In the second half of the twentieth century, there has been a more gradual worldwide shift in favor of English, which is fast becoming an important and popular second foreign language even in the most strongly entrenched, defiantly non-English region of the Third World (Francophone West Africa). Some linguistic phenomena associated with relexification of borrowed vocabulary in such contexts were touched on in Sects. 2.3 and 3.2.

4.3 Diglossia

'Diglossia,' a term introduced by Charles Ferguson (See *Ferguson, Charles A*; *Diglossia*), is the co-occurrence in a community of sharply different H and L ('high' and 'low,' i.e., official versus vernacular) varieties of the same language. The somewhat provocative labels high and low generally reflect the attitudes of native speakers, not of the sociolinguists who study the systems. To some extent, any language that is spoken on the streets, is written, and is used in schools and other formal contexts is characterized by some high/low variation, but the term 'diglossia' is most often applied in cases like Arabic and (Modern) Greek, where the language of writing (and of lectures and news broadcasts) is quite distinct from the modern vernacular. Standard Literary Arabic, for example, is close to the language of the Qu'rān and does not vary from one Arab country to another, while dozens of mutually unintelligible vernaculars have developed, from Timbuktu to Central Asia, in the intervening 1300 years. Until the Romance languages became widely used in writing during the Renaissance, one could describe their relationship to Latin as diglossic, though for the illiterate masses the matter was mostly irrelevant to daily life.

Diglossic borrowing (from the H variety into the spoken L form) is rather similar to borrowing from a colonial language. Again a local vernacular is up

439

against a dominant international or at least suprar-egional variety used in schools, writing, and broadcast media, in a world with ever increasing literacy and exposure to media. Accordingly, the type of vocabulary that is borrowed from the H to the L variety tends to be of the same semantic types as in colonial contexts. In Morocco, where the local Arabic dialects borrow both from French and from Literary Arabic, these latter compete as suppliers of new borrowings, and although there is a partial division of labor (Literary Arabic for Islamic subjects, French for sports), this division is not sharp and is being undermined by shifts in official language usage (the gradual Arabization of the educational system and the bureaucracy). Because the diglossic H form is not considered foreign, there is no puristic weeding out of diglossic borrowings (as there often is with foreign ones).

Mechanically, diglossic borrowing is much more straightforward than borrowing from unrelated or distantly related foreign languages. Since the vernacular already shares many true cognates with the H variety, phonological and morphological correspondences are usually obvious, and new borrowings can simply follow these correspondences. Some diglossic borrowings may form an identifiable lexical stratum by virtue of containing a sound or other feature not characteristic of the L variety, like Moroccan *suʔal* 'question' (glottal stops occur in Literary but, except for such borrowings, not in vernacular Moroccan). However, large numbers of diglossic borrowings blend imperceptibly into the L variety.

Subordinating particles and connectives noted above (Sect. 2.5) for bilingual borrowing are also important in diglossic borrowing. For example, younger Moroccans regularly use such Literary Arabic clause-introducers as *bi-ʔanna* 'that' (quotative) and *li-ʔanna* 'because' instead of older dialect forms, a change with important syntactic ramifications.

4.4 Native Minority Communities

In the colonial cases discussed in Sect. 4.2 the politically dominant group is less numerous than the native population. However, there are also cases, notably in the Americas and Australia, where the native ethnic groups have been overwhelmed numerically by the intruders and have come to function permanently as ethnic minorities. A considerable variety of linguistic scenarios can develop in the situation, depending on such factors as the size, degree of intactness, and isolation of the minority groups, as well as less easily measurable cultural phenomena. Thus, in the Americas, the number of speakers of Nahuatl and Quechua, or even Navajo, has assured the vernacular viability of the languages despite extensive bilingualism with English or Span-ish; some much smaller groups in the pueblos or canyons of Arizona and New Mexico have remained relatively intact due to conscious resistance to cultural domination. On the other hand, many Native American and Australian languages have already disappeared and others are dying off.

As long as the minority language (see *Minority Languages*) remains viable as a vernacular, the type of borrowing observed is similar to that found in ordinary colonial situations like Morocco, the Philippines, and Indonesia. However, as minority languages lose their viability and head toward eventual extinction, more extreme phenomena connected with 'language death' (see *Language Maintenance, Shift, and Death*) are observed. The native language, whose grammar is subject to simplification and instability among marginal speakers (e.g., when addressing monolingual grandparents), ceases to be the unquestioned base language for code-switching and the target language for borrowing. Instead, some form of the dominant majority language comes to be used among younger members of the minority group. At a certain point, the native language, along with other forms of traditional behavior associated with aged persons, comes to be viewed by the newer generation as a quaint anachronism or a symbol of low status, and as their elders die off the native language vanishes with them.

In this drastically altered landscape, one might still be able to speak of a 'minority dialect' (e.g., Native American English) of the majority language spoken among members of the minority. In some cases, a pidgin or creole may have developed among the natives, the lexicon coming mostly from the majority language (see *Pidgins and Creoles: An Overview*); later on this will slowly decreolize, producing a narrower continuum with the standard form of the majority language (an example is Australian Aboriginal English). In less extreme cases, the most consistent marker of the native dialect may simply be a noticeable accent. However, even as the minority dialect shows signs of merging completely with the standard majority language, a small number of highly visible and symbolically important borrowings from the original native language are maintained or even resurrected as expressions of ethnic identity. It is debatable whether such forms should be considered as borrowings into the majority language, or as the residue that has survived a continuous piecemeal replacement of minority by majority language material.

4.5 Immigrant Communities

Until the early-twentieth century, immigrants to the Americas could, if they wished, obtain unoccupied farmland and recreate in the New World the towns they had left behind. Since then, immigrants have

formed ethnic neighborhoods or small kin-based networks, usually in large cities.

A wide variety of attitudes and behaviors toward language are observed within immigrant families, whether the children came with the parents or were born in the host country. Sometimes the parents attempt to maximize the use of the ethnic language (and ethnic culture in general), an approach that may reflect the hope of returning to the motherland, but may also be associated with strong parental control of children's behavior. Alternatively, some parents make explicit decisions to shift to the new majority language, an approach that may be consciously intended to improve the children's educational and career prospects.

In any event, sociolinguistic forces within immigrant neighborhoods or even simple families are extraordinarily complex, as the choice of spoken language becomes a critically important and easily manipulable symbol of identity. Moreover, in such communities there is considerable asymmetry in degrees of mastery of the respective languages, not only across generations but also, say, between elder and junior siblings within a family. Unless the ethnic community is regularly replenished by new waves of immigrants, linguistic assimilation is usually complete no later than the third generation (the second born in the new country). However, even at this stage, if ethnic identity has retained any significance in the host country, interesting ethnic varieties ('ethnolects') of the majority language may persist, consisting of a slight accent along with a repertoire of lexical items borrowed (or retained) from the ethnic language. Some of these lexical items are not understood by nonmembers, so the variety can function as a litmus test for ethnicity and as a barrier. A third-generation immigrant who smiles at the quaintness of his/her grandparents and has no strong identification with the old country may nonetheless find considerable satisfaction in using the ethnolect with peers, since it effectively expresses a special, intermediate identity.

Under very particular conditions, ethnic languages and dialects can endure over centuries. This happens when minority ethnic or religious groups coexist with majority populations over many generations but remain residentially and socially segregated. Jews in Europe and in Arab countries, particularly before the Nazi genocide (1939–45) and the mass immigration to Israel (after 1951), furnish many examples. The boundaries between Jews and Gentiles in some regions were sufficiently sharp to permit long-term coexistence of mutually unintelligible languages (Yiddish and Ukrainian; Judeo–Spanish and Bulgarian; Judeo–Arabic and Berber). In other cases, local populations of Jews and Gentiles spoke structurally quite distinct dialects of the same language (Yiddish and German, Judeo-Arabic and Muslim Arabic).

Under late-twentieth-century conditions in Europe and the USA, some but by no means all Jews can still be readily identified by accent (especially in New York City and Philadelphia, where there are large Jewish concentrations). Some speakers can switch into an in-group, Jewish English ethnolect (often known as 'Yinglish') involving a variable amount of Hebrew and Yiddish vocabulary in an English base.

4.6 Decreolization

A pidgin is a relatively unstable variety developed in marketplaces, plantations, and similar environments for limited communication among native speakers of different languages; a creole is a pidgin that has become a native language for a new generation and has stabilized its grammar accordingly. Most pidgins and creoles (see *Pidgins and Creoles: An Overview*) are lexically derived from a European language (English, French, Portuguese, etc.). Of interest here is the fact that creoles tend to undergo extensive grammatical and lexical change subsequent to their emergence.

In many cases, the creole continues to be in a diglossic relationship to its original lexifier language—creole and standard English in Jamaica, creole and standard French in Haiti, creole and standard Portuguese in the Cape Verde Islands. In this case, the diglossic borrowing patterns described in Sect. 4.3 are applicable. The resulting convergence of the creole with the lexifier language is called 'decreolization.' In such contexts, there is a continuum of varieties ranging from the 'acrolect' (the standard European language) through the intermediate 'mesolect' to the 'basilect' (closest to the original creole), with the long-term tendency generally a contraction of the continuum around the acrolectal pole.

However, the vicissitudes of politics may result in the superimposition of a distinct European language on the creole. Tok Pisin (spoken in Papua New Guinea) is usually classified as an English-based creole, but it originated as a German-based creole (or pidgin) and was relexified when German power ended in the region. A major topic in creolistics is the difficult philological unraveling of similar replacements of lexifier languages in the early development of other pidgins and creoles, such as Papiamentu (Guianas) and Hawaiian Pidgin. In any event, relexification is basically the same process whether the target language is a creole or an ordinary language with a large stratum of borrowings (cf. Sect. 2.3) (see also: *Pidgins and Creoles: Morphology*; *Pidgins and Creoles: Models*).

4.7 Purism—The Target Language Fights Back

Even in unofficial contexts, borrowing (and code-switching) has powerful symbolic connotations. In many cases, borrowings are highly conspicuous,

perhaps because of some telltale phonological or orthographic feature or just because most people know they are foreign. Borrowings are therefore a prime target of linguistic nationalists and (other) purists, who find them an insult to their language.

The formative period of Modern Turkish is an instructive example. Under the influence of a charismatic political leader, Attatürk, Turkey emerged as an independent country after World War I, and promptly set about refashioning its cultural and political allegiances, shifting away from the Arabo–Persian sphere into the European one. The Arabic script that had been used in Turkish under the Ottoman Empire was thrown out in favor of the Latin orthography still in use. Official committees sifted through the lexicon, throwing out hundreds of well-entrenched Arabic and Persian borrowings, and incorporating many new borrowings from European languages. In case this latter development was interpreted as a challenge to Turkish sovereignty, the 'sun language' theory was propounded, claiming that Turkish was the original human language, so that borrowings from European languages were long-lost brethren being belatedly reintegrated into the fold.

Every modern standard language has passed through periods of intense lexical development, and in each case an elite group had to decide how to produce new vocabulary. The Romance languages, and to a large extent English (with its significant component of French borrowings dating to the Norman period), mined Latin and to some extent Greek for much of this vocabulary. The development of standard German took a mixed approach, accepting some of this Latinate vocabulary (along with many French borrowings), but self-consciously balancing them with internally generated German compounds—often transparent calques like *Fernsehen* modeled on television ('distant-seeing'). When literary Arabic was developed in the early Caliphate, Greek academic vocabulary was the semantic model, but new vocabulary was generated from Arabic roots using various derivational mechanisms, rather than by direct borrowing from Greek, and written Arabic continues to avoid European borrowings. Scholars engaged in the development of other standard languages (Basque, Swahili, Tok Pisin) continue to agonize over this perennial issue. In the case of standard French, the elite is less concerned with expanding an already impressive vocabulary than with stemming an unseemly flood of English borrowings.

4.8 Borrowing and Special Registers

While the conspicuousness of borrowings makes them anathema to patriotic purists, it may also make them attractive in various special contexts. A sprinkling of foreign words gives sociolinguistic content to an ethnolect (Sect. 4.5), and a *je ne sais quoi* of erudition to a highbrow conversationalist. Urban street slang is a fertile ground for borrowings, at least in bilingual areas. Moroccan slang (from Fes) provides such examples as *kambu* 'country bumpkin, hick' (old borrowing < Spanish *campo* 'field'), *xwadri* 'pal, brother' (playful mixture of Moroccan *xu-* 'brother' and the Spanish kin-term type seen in *madre* and *padre*, with the canonical shape *CCaCCi* influenced by a Moroccan derivational formation of this template), the diglossic slang expression *l-ʕadama* 'terrific!' (< Literary Arabic 'magnificence' or 'majesty'), and the English loan *tt-sṭuna* 'get stoned (on drugs, etc.).'

Code-mixing
R. Mesthrie

The term 'code-mixing' is a fluid one that overlaps with 'code-switching' and 'mixed code' (see *Code-switching: Overview*; *Intertwined Languages*), but can be distinguished from them in some ways. However, the terms are sometimes used interchangeably and not all contact linguists (including the influential Myers-Scotton, see *Myers-Scotton, Carol*) would agree that the terms are distinguishable. Milroy and Muysken (1995: 12) describe the failure of prominent researchers working on a European

Science Foundation project to come to agreement on terminology:

> ... the field of code-switching research is replete with a confusing range of terms descriptive of various aspects of the phenomenon. Sometimes the referential scope of a set of these terms overlaps and sometimes particular terms are used in different ways by different writers. When we started working together in the Research Network, one of our first endeavours was to standardise this terminology, with a view to imposing some order on a heterogeneous field of enquiry and ultimately producing rather more reader-friendly publications. This soon turned out to be an impossible task, and as a consequence no clear set of defined terms uniformly used by all authors can be found in this book.

Insofar as a distinction can be made we might say that prototypically code-switching is relatively 'clean' while mixing is relatively 'ragged.' That is, the breaks between the two codes being switched are more or less discernible (e.g., formally, across clauses or sentences; or functionally, to include a newcomer who knows only one of the codes). For code-mixing the breaks between the codes are somewhat blurred, constant switching back and forth within clauses would prototypically count as mixing. Thus code-switching leans towards the transactional, the situational, or the pragmatic—as when people switch codes according to topic or interlocutor appropriacy, say in switching from a local language like Luhya to another language of wider communication like Swahili at a marketplace in Kenya. On the other hand, code-mixing leans more towards the metaphorical function or solidarity functions as when speaker and listener are both familiar with more than code and may interchange them for special effect. The very act of mixing codes signals allegiance to a particular relationship, or local set of values. That is, the code interchange is not functional in a pragmatic sense, but rather symbolizes a lifestyle and attitude to language (hence metaphorical). Such codes may even have names that are often derogatory: e.g., Tex-Mex for code-mixing between English and Spanish in Texas.

Sometimes frequent mixing may become the norm; Myers-Scotton (1993) calls this an unmarked variety. In such a case a mixed code may well stabilize. This seems to be happening increasingly in many urban centers. However, not all code-mixing leads to a mixed code. That is, code-mixing may remain a strategy exhibited by some speakers, rather than

a stable, (covertly) socially sanctioned code. Bakker and Muysken (1995) prefer the term 'intertwined languages' (see *Intertwined Languages*) in cases where the grammars of the two codes are woven together in clearly predictable ways. Thus, Michif, a North American contact language (see *Contact Languages*) has its verb phrases from Cree and its noun phrases from French (Bakker and Muysken 1995). Not all mixed codes are as predictable as this however; and it makes sense to differentiate intertwined languages as a special class of mixed codes.

Finally mixing can involve borrowing (see *Borrowing*) but is theoretically (if not always in practice) distinguishable from it. The term 'nonce borrowing' is sometimes used to show up the similarity between code-mixing and borrowings that are not established or not permanent (alternating with a word from the other language). Essentially, borrowing does not presuppose mastery of the code being borrowed from—one can use the word *perestroika* without knowing Russian. Prototypically, code-mixing does presuppose the mastery of the codes being mixed. This can be shown when in certain domains speakers might 'unmix' them; e.g., a person may speak in a mixed code *A–B* to a friend, but only use *A* with parents and only *B* with a schoolmaster. For a mixed code to be identified there ought to be a generation (or a particular social group) for whom such 'unmixing' is not possible for at least one of the two codes *A* and *B*.

Code-switching: Discourse Models

P. Auer

One way of looking at bilingualism is to take the perspective of the bilingual conversationalist. For him or her, being bilingual means first of all being able to use two or more languages in conversation.

Although this ability to code-switch may not always be appreciated in the bilingual communities themselves, it provides specific resources not available to monolingual speakers for the constitution of socially meaningful verbal activities.

1. Conversational Code-switching

It is useful to start the discussion with two somewhat extreme positions on the meaning of conversational code-switching. The first one assumes that certain conversational activities prompt the usage of one language or the other qua activity type. A particular activity type is seen as being linked to language B such that in the environment of language A, code-alternation occurs as soon as conversationalists initiate this activity type. Code-switching occurs quasi accidentally as a consequence of alternating between activity types (cf. e.g., Fishman 1965, 1971). Blom and Gumperz (1972) speak of 'situational switching' (a notion taken up in Myers–Scotton's 'code-switching as the unmarked choice,' 1993), and believe that the situation determines language choice. The weakness of this approach becomes apparent as soon as language choice is investigated empirically. In modern bilingual societies, the relationship between languages and speech activities is by no means unambiguous. Many speech activities are not tied to one particular language, and even among those which have a tendency to be realized more often in one language than in another, the correlation is never strong enough to predict language choice in a more than probabilistic way.

The opposite view would hold that the conversational meaning of code-switching results from the mere juxtaposition of two codes which has a signaling value of its own, independent of the direction of code-alternation. No association between languages and speech activities needs to be presupposed. Rather, the language chosen for one utterance must be seen against the background of language choice in the preceding utterance. From this perspective, the question is not what verbal activities are associated with one language or the other, but instead: during which activities do bilinguals tend to switch from one language into the other. In answering this question, researchers on code-alternation have developed elaborate typologies of code-switching. They seem to converge across bilingual communities on certain conversational loci in which switching is particularly frequent (cf. Gumperz 1982), such as: (a) reported speech; (b) change of participant constellation, particularly addressee selection (this includes the use of code-switching in order to include/exclude/ marginalize co-participants or by-standers); (c) parentheses or side-comments; (d) reiterations, i.e., quasi-translations into the other language, for example for the purpose of putting emphasis e.g., on demands or requests (cf. Auer 1984b) or for purposes of clarification, or for attracting attention, e.g., in the regulation of turn-taking (e) change of activity type, also called mode shift or role shift; (f) topic shift; (g) puns, language play, shift of key from serious to playful or the other way round; and (h) topicalization, topic/comment structure.

Although lists such as this one are useful because they demonstrate that some conversational loci are particularly susceptible to code-alternation, the mere listing of such loci is problematic, for it can tell us nothing about why code-alternation may have a conversational meaning or function. The list itself will hardly ever be a closed one, which shows that code-alternation is used in a creative fashion, and that it can have conversational meaning even if used in a particular conversational environment only once. Also, the listing of conversational loci for code-alternation implies that code-alternation should have the same conversational status in both directions, i.e., from language A into B or vice versa. However, although the conversational loci for alternation listed above may in fact be used for switching in both directions in one and the same speech community, the exact conversational meaning of these cases of alternation is often not identical (cf., e.g., Auer 1984a, 1984b, Gal 1979: 112ff, Sebba and Wootton 1998, and particularly Alfonzetti 1998 for a careful discussion).

2. Conversational Patterns of Switching

In the typical bilingual speech community, the correlation between language and activity is not strong enough to make code-alternation predictable, but the direction of switching is nevertheless important for reconstructing its conversational meaning in most communities. How can this situation be accounted for? A number of studies have attempted to answer this question by applying conversation analytic methodology to code-switching, and by subjecting this phenomenon to a strictly sequential analysis (Auer 1984a, Li Wei 1994, 2002, Shin and Milroy 2000). This conversational approach has partly been complemented by looking at the meaning of code-switching as a contextualization cue, i.e., a means by which participants can contextualize the conversation locally (Gumperz 1982). Paying close attention to the details of the conversational level does not imply that 'macro' dimensions are irrelevant for the interpretation of code-switching for these researchers. Quite the contrary, the indexicality of patterns such as the ones proposed in Auer (1984a) and schematized in Auer (1995: 125ff.) provides a built-in sensibility for these

dimensions: conversational regularities are both context-independent and context-sensitive. Investigation of a particular instance of switching will therefore consist of a sequential analysis of its occurrence, as well as an analysis of how the switching indexes values and stereotypical experiences attached to the two languages in the community (if any).

The most important conversational patterns of switching may be described as follows:

2.1 Discourse-related Alternational Code-switching

This refers to the alternation between a stretch of talk in one language and a stretch of talk in the other with the aim of structuring and organizing the conversation; schematically:

Pattern Ia: ... A1 A2 // B1 B2 B1 ... or
Pattern Ib: ... A1 // B1 B2 B1 B2 ...

(Where letters stand for languages, and numbers for speakers.) For instance, a stretch of talk in language A addresses one co-participant, and the subsequent stretch of talk by the same speaker in language B addresses another coparticipant.

2.2 Discourse-related Insertional Code-switching (Ad Hoc Borrowing)

This is the insertion of language B materials into surrounding talk in language A, again with the effect of structuring the conversation or contextualizing the meaning of the utterance in which it occurs. For instance, a lexical insertion may evoke some particular effect such as turning the utterance into a humorous one:

Pattern II: ... A1 [B1] A1 ...

The same (i.e., insertional) pattern also occurs without a discourse-related interpretation, as a consequence/indication of a speaker's or recipient's lack of competence in language A (competence-related insertional code-switching).

2.3 Preference-related Alternational Code-switching

This involves the following pattern:

Pattern IIIa: ... A1 B2 A1 B2 A1 B2 A1 B2 ...
(sustained divergence of language choices between two participants) or
Pattern IIIb: ... A1 B2 A1 B2 A1 // A2 A1 A2 A1 ...
(language negotiation sequence: convergence of language choices; cf. Auer 2000).

3. Analyzing the Patterns

In contrast with discourse-related switching, where the new language prototypically evokes a new 'frame' or 'footing' for the interaction which is then shared by all participants, preference-related switching results in more or less persistent phases of divergent language choices. This is a marked state of affairs for many bilingual speech communities, though certainly not for all, which is often accounted for by reference to certain attributes of the individual who performs this switching, or his or her coparticipants (hence the notion of participant-related switching in Auer 1984a). The exact nature of this ascription is dependent on the wider social, political, and cultural context of the interaction at hand (cf. Rampton 1998).

Discourse- and preference-related switching are not strictly separated. In pattern IIIb, for instance, the transition from divergent to convergent language choices (i.e., the moment where one common language-of-interaction is found) may take on discourse-related meanings. The same holds for the beginning of a sequence of divergent language choices, unless it coincides with the beginning of the episode as a whole.

The focal case of most research on code-switching has been Pattern I so far. In Auer 1999, I have portrayed the prototypical case of this discourse-related, alternational code-switching as follows: (a) It occurs in a sociolinguistic context in which speakers orient themselves towards a preference for one language at a time; i.e., it is usually possible to identify the language-of-interaction which is valid at a given moment, and until code-switching occurs; (b) through its departure from this established language-of-interaction, code-switching signals 'otherness' of the forthcoming contextual frame and thereby achieves a change of 'footing.' The precise interpretation of this new footing needs to be 'filled in' in each individual case, although previous episodes may also be brought to bear on the interpretation of the case at hand; (c) it seems possible to describe the mechanisms by which code-switching relates to the two codes and to the context in which it occurs in very general ways. Contexts are theoretically innumerable, of course, as are the interactional meanings of code-switching; however the ways in which these meanings are construed remain constant from one community to the next; (d) code-switching may be called a personal or group style. As a group style, its use may be subject to normative constraints valid within a speech community; however, it certainly is not a variety in its own right; (e) most code-switches occur at major syntactic and prosodic boundaries (at clause or sentence level). Since switching serves to contextualize certain linguistic activities, the utterance units affected by the switch must be large enough to constitute such an activity. For this reason, code-switching (in this restricted sense) does not provide much interesting data for syntactic research; (f) although code-switching bilinguals may be highly proficient in both languages, balanced proficiency is by no means a

445

prerequisite. Indeed, code-switching is possible with a very limited knowledge of the 'other' language.

In order to ascertain that we are dealing with code-switching in a particular case of the juxtaposition of two co-occurring sets of structural parameters, it is essential to show that speakers orient themselves towards this juxtaposition. Therefore the question of what counts as a code must refer to participants', not to linguists' notions of 'code A' and 'code B.' An 'objective' statement (i.e., one exclusively informed by the 'linguistic facts,' such as (the absence of) phonological or morphological integration, or frequency) that a given arrangement of signs constitutes a combination of elements of two systems is not only very difficult to make at times, it is also irrelevant. There may be cases in which the two codes juxtaposed are 'objectively speaking' very similar, yet regarded by the members of a bilingual community as completely separate (as in some cases of some dialect/standard switching; cf. Alfonzetti 1998 for Sicily), just as there may be codes which are 'objectively speaking' very distinct but nevertheless are seen as nondistinct by the speakers. Also, it needs to be remembered that the languages involved in code-switching in a bilingual community may be considerably different from their monolingual relatives due to convergence as a consequence of long-standing language contact (cf. Clyne 1987, Gumperz 1982: 84ff.). A methodology to prove participants' orientation towards the juxtaposition is precisely to show that it is used as a contextualization cue (i.e., that it is 'functional' cf. Alvarez-Cáccamo 1998). Further evidence is provided by self- and other-corrections of language choice (cf. Gafaranga 2000).

Keeping this restricted and strict notion of (discourse-related) code-switching in mind, it goes without saying that there are many phenomena of bilingual speech, which do not conform to it. Those, in which the boundaries between one language and the other are less clear, in which the notion of what is language A and what is language B is open to dispute, in which the preference for one language at a time does not hold and in which the use of more than one language may not carry any or only highly ambivalent meanings (cf. Woolard 1999). The large field of these 'other' phenomena of bilingual speech is subsumed under various headings, such as 'mixing' (Auer 1999, Meeuwis and Blommaert 1998), 'frequent code-switching,' or 'code-switching as the unmarked choice' (Myers-Scotton 1993). The question of how in these forms of talk an analysis can be made from a discourse perspective is still largely open.

Code-switching: Overview
K. M. McCormick

Taken broadly, the term 'code-switching' refers to the juxtaposition of elements from two (or more) languages or dialects. There is, however, little agreement among scholars on either the semantic scope of the term as they use it, or the nature of distinctions to be drawn between it and other, related terms such as diglossia, code shifting, code mixing, style shifting, borrowing. Despite several papers addressing the problems of terminological confusion, there is still no consensus.

Disagreement arises on classificatory criteria such as length of the juxtaposed utterances (whole discourses at one end of the spectrum, to single words containing morphemes from two languages, at the other); density of switches in a given spoken or written text; whether the switch in question is an individual and unusual one or an instance of a type that is common in the speech community; the presence or absence of social significance in the switch and, where the switch is significant, the nature of that significance; consciousness on the part of the speaker that elements from two codes are being used. Figure 1 is a schematic representation of what the terms have, variously, been used to signify with regard to relative length of juxtaposed elements and density of switching. It is no more than a rough guide to indicate areas of overlap or synonymy.

Terms	Length of juxtaposed utterances	Density of switching
diglossia	whole discourse types	low
situational code-switching	whole conversations, in one context	low
metaphoric code-switching	whole conversations, each within one role relationship	low
conversational code-switching; style shifting; code mixing	whole conversational turns/chunks within a turn: whole sentences or clauses/whole clause constituents	high
single-word code-switching; borrowing	words	low/high
integrated loanwords	morphemes	low/high

Figure 1. Schematic representation of scope of terms used to designate types of code juxtaposition.

Code-switching of all kinds is of interest to sociolinguists, while particular types are of interest to other disciplines. Switches involving longer elements such as whole discourses indicate something about societal patterns and are thus of interest to sociologists and anthropologists. Conversation analysts examine switches of all types that occur within a conversation since they are often ways of realizing various conversational strategies. Of interest to psycholinguists are questions of how the brain stores, distinguishes between, and selects various codes for use in particular instances. A rich field for syntacticians is the area of intrasentential switching between languages, especially in cases where the rules for the formation of particular structures are different in the two languages. For linguists in general, code-switching raises metatheoretical challenges. These include how to conceptualize boundaries between languages; how to develop criteria for classifying loanwords; how to use the scope of analytic models using binary opposition and those using the idea of a spectrum; and how to exploit the heuristic value of system-based and speaker-based perspectives on data (see *Language in Society: Overview; Sociology of Language; Code, Sociolinguistic*).

This article deals with topics and developments within the field of code-switching research in the order in which they arose, which is roughly as follows. Early work (in the 1950s and 1960s) focused on the functional distribution of codes in speech communities. Arising out of this work was research which looked at the factors that facilitated or prevented the acquisition of particular codes by some social groups but not others, and at the relevant societal power-relationships between the groups. Complementary to this concern with broad societal dynamics was the narrower focus—particularly by conversation analysts—on how individuals deployed their repertoire of codes, for example switching from one to another in order to shift the balance of power during a conversation, or to achieve a particular stylistic effect. By the mid-1970s syntacticians were examining the structures of intrasentential code-switches to see what kinds of rules governed them. During the course of this work questions arose about the relative merits of different explanatory models and different kinds of grammar. This, in turn, has led to a radical questioning of assumptions on which earlier work was based, for example the assumption that dialects are sufficiently distinguishable from one another linguistically to make possible the identification of points at which there is a switch from one to another. In the 1990s an important

447

research focus was the relationship between the associations that a language variety as a whole had in a community, and the significance of a switch to that language variety in a particular conversational turn. It was found that there is not necessarily a transfer of associations from the macro to the micro level. Much contemporary work on code-switching is metatheoretical, seeking to construct theoretical models which take into account the social, grammatical and cognitive aspects of code-switching. (See for example Tabouret-Keller 1995.) For a sense of recent directions and findings in code-switching research, see the papers in Milroy and Muysken (1995) and Auer (1998).

1. Code-switching Governed by Societal Norms

In diglossic speech communities (see *Diglossia*) the functional distribution of codes is publicly acknowledged and institutionally supported. As the term 'diglossia' suggests, there are two codes that feature prominently in the community. One is used on high status occasions (and has come to be referred to in studies of diglossia as the 'H code'), and the other is used for more mundane, low status functions (and is known as the 'L code'). In such communities there is very little overlap in the codes' functions. Typically, the H variety is learned at school, not at home, and is reserved for very formal discourse such as public prayer, secular ceremonies, legal transactions, news broadcasts. The other code is used for less formal discourse, for example for discussing a lecture given in the H variety. The H may be a classical form of the language (as in the case of literary Tamil and classical Arabic) as distinct from the local contemporary dialects of those languages which are used for L functions. The H may also be the contemporary standard dialect (for example standard German in Switzerland) as distinct from a regional dialect (like Swiss German). The term 'diglossia' has been extended to cover situations where the H and L codes are different languages, one of which has greater prestige than the other. All members of a diglossic speech community would know that they ought to switch to the H variety in particular circumstances but in those communities where the H variety is learned only through formal education, people whose formal education was limited would not be able to code-switch with ease: they would be unable to use the H code in any but the most ritualized exchanges for which appropriate responses could have been learned by rote.

In many bidialectal, bilingual, or multilingual speech communities distinctions among occasions and codes are not primarily hierarchical: the codes may be perceived as different but be equally valued, and similarly the situations may be differentiated on grounds other than prestige. This 'looser' kind of code-switching for different occasions is commonly referred to as 'situational code-switching.' Although the term foregrounds the situation, other factors which are relevant in determining code choice are: what the topic of conversation is and who the speakers are—this includes a consideration of their roles and of their personal relationship. An account of situational switching which gives both broad patterns and cameos of interpersonal interaction is to be found in Denison's (1972) study of a speech community in northern Italy (see also *Speech Community*; *Role Theory*).

At the time when the study was done, everyone in the district of Sauris spoke dialects of Friulian and German and the national language, Italian. There were clear norms of appropriateness governing code choice: German was for use between spouses in the home; Friulian with neighbors in informal settings such as the market and the tavern; and Italian for more formal interactions centered on church, school and the workplace and also for use in the presence of strangers. There was a developing tendency for parents to try to use Italian at home with their children in order to promote their skill in the language of the school.

In communities like this one where the domains requiring different codes are those of everyday life, it would be normal for adult members of the speech community to have a good command of all codes because they would use all of them fairly frequently. Competence in switching appropriately would not be the preserve of those with formal education, as is the case in many diglossic communities. Inappropriate language choice would be recognized as a breach of convention with particular social significance, as is seen in Denison's account of an incident in a Saurian tavern.

An argument took place between husband and wife in the tavern, a public but informal setting where the normal code choice would be Friulian. The husband was in the tavern talking to his friends when his wife entered, clearly angry. She addressed him in German, the language of the home, thus defining the situation as a domestic one. He replied in Friulian, attempting to redefine it as a public social occasion where domestic strife should not appear. After just one phrase in Friulian she resisted the switch, persisted in German, and he eventually capitulated, in German. What seems to be at issue is the definition of the social space as public or private: if public, Friulian would be spoken and a domestic row would be out of place; if private, German would be used and domestic strife would be accommodated. The speakers' initial resistance to each other's code choices was part of the contest for power.

An uncontested change of code during an interaction between two people can mark the foregrounding of a different facet of the relationship between them. Scotton (1979: 85) provides an example of such a switch which has the effect of limiting the scope of one set of rights and obligations and bringing

another set into play. The encounter took place in a shop in Kenya.

> A brother who runs a wholesale shop greets his sister, who has come to buy a few grams of salt. Both are Babukusu (a subgroup of the Baluyia). The brother greets the sister in their own first language, Lubukusu. But he soon switches to Swahili, the locally recognized language of trade. 'This codeswitching reminds the sister that the shop is run as a business geared to profit-making,' reported our correspondent about this incident. 'By continuing to speak some Lubukusu, he lets his sister know that he remembers their relationship, but by speaking some Swahili, he reminds her that he is a businessman and that she cannot ask for more free salt.'

It is possible that all participants in conversation quite unconsciously use a code which they consciously regard as inappropriate for a particular circumstance. This was observed in a village in northern Norway when students, home on vacation from a university further south, were engaged in arguments among themselves in which their intellectual status was at issue. On these occasions they switched to the standard language, Bokmål, from the local dialect, Ranamål, towards which they had very positive feelings and which is the only dialect regarded as appropriate for informal conversation among friends. Blom and Gumperz (1972) report that the students were shocked to find that they had switched in this way and undertook to refrain from doing so in future, their use of Bokmål having transgressed norms that they respected. In spite of their determination, further transgressions occurred. Instances such as these suggest that code-switching is not always a matter of conscious choice and control.

In sum, if there is a change in any one of the factors associated with situational switching—context, topic, participants—or if there is a change in perceptions of that factor, it may trigger a switch to another code (see also *Bilingualism, Societal*).

2. Conversational Code-switching

Conversational code-switching differs from situational switching in that its occurrence is not dependent on a change of interlocutors, topic or situation. It is to be found within conversations and not necessarily only between turns—a switch may take place within one speaker's turn as it does in the following sentence (Gumperz and Hernandez-Chavez 1972: 87):

> *Te digo que este dedo* has been bothering me so much [I tell you that this finger ...]

The factors governing conversational switching appear to be more subtle than those involved in situational switching. Consequently, they may be harder to identify with certainty. In some cases—like the switch quoted above—they are practically impossible to account for. At times speakers are conscious of switching while at other times they are not. Switching by fluent bilinguals serves a range of stylistic purposes and may also signal minor fluctuations in the interlocutors' feeling towards each other during the course of the conversation in which the broad roles remain the same.

Research into conversational code-switching has three main foci: the social factors underlying switching, the stylistic and other pragmatic effects achieved by it, and the linguistic features of discourse containing frequent code-switches. The first two are dealt with in this section and the third in Sect. 3.

Whether or not, and how a speaker switches languages or dialects during a conversation may convey social information. It may, for example, indicate the recognition of a bond between interlocutors arising from shared background or interests. This purpose can be served by switches of different lengths and density.

If dense code-switching is a preferred mode of discourse in a group it may come to be, itself, a code that is to be distinguished from monolingual codes in the wider community. Where this has been documented, the mixed code serves to identify its users as people who, for various reasons, do not feel part of the communities most strongly associated with either of contributing languages. The mixed code can serve as an indicator of group identity. It has done so for many Chicanos in the Southwestern USA who feel that they are a group distinct from non-Hispanic English speakers and also from Spanish-speaking Mexicans. One way of indicating their group identity as Chicanos is to draw freely on both languages. This practice results in a code which speakers use when the context demands a contrast with the standard dialects of the two contributing languages and what they symbolize. A working-class speech community in South Africa, classified 'colored' and marginalized through the application of a series of apartheid laws, reveals its dissociation from white English and Afrikaans speakers and from the middle class, linguistically. It is unacceptable to speak the standard dialects of either language to one's neighbors. The vernacular, characterized by dense code-switching, is at once the medium of communication and a powerful symbol of belonging to the local community. In response to the question about what would happen if a neighbor addressed one in standard English or Afrikaans, the following was a typical response:

> For one thing I think the person himself will feel quite awkward. People would look at him strange, you know. They'd straight away identify there's something wrong with the person's speech and he will automatically try to rectify it and try to join in. I think that is why people mix their language also, you know.

(McCormick 1990: 91)

449

An aspect of a speaker's identity can also be signaled by a brief excursion into a second code: by dropping a word or phrase from another language or dialect into a conversation, a speaker can make evoke a reference group that would be recognized by other participants. For example, using a Yiddish exclamation such as 'Oi gewalt!' in an English conversation gives a glancing acknowledgment of Jewish background. Such switches often serve as much a symbolic function as a referential one. They mark the speaker as an insider in the domain or reference group in which the term has currency. Speakers who switch in this way may or may not wish to suggest that the interlocutors are also insiders. They do not always indicate that the speakers are proficient in the language or dialect from which the phrase was taken—often they are not. Limón (1982: 320) discusses the conscious political and strategic use of code-switching made by members of a Chicano student society. One of the means by which they try to gain credibility is to switch of folk Spanish, as is indicated by an interviewee (see also *Ethnicity and Language*):

> Yeah, with these guys you have to do that [use Spanish] otherwise nobody listens to you … it's really funny … even though the members don't speak that much Spanish … if you don't use some … they'll think you're *agringado* … these guys are good at it *y te chingon* [they'll screw you].

Switching back and forth between two languages or dialects can be a strategy to indicate a speaker's neutrality with respect to contending parties or ideas if these are associated with different codes (Scotton 1979).

Among speakers who share a command of the same code repertoire, switching can be a means of achieving a range of stylistic effects within a conversation. Sometimes a speaker will switch to another code while making a remark that is not part of the main narrative. The switches into and out of a new code mark the boundaries of the parenthetic remark. According to Sebba and Wootton (1984: 4), this is what happens with the switch from London Jamaican into London Black English in the following extract of a conversation where the speaker interrupts her main narrative to try to recall when the event took place:

> *man Leonie 'ave party when* … don' remember when it was *bot shi did tel aal o dem no fi (t) se notin kaaz shi no waan tu moch Catford gyal di de*
> [man Leonie had a party … but she did tell all of them not to say anything because she didn't want too many Catford girls there]

Material may also be foregrounded by a change of code. This often happens when someone quotes what was said on another occasion: the quoted words are given in a code other than the one being used in the current conversation to distinguish them from it. The examples below show a switch from Judeo-Spanish to Hebrew (Berk-Seligson 1986: 323–4):

> Le diši *'ma aní asé?'*
> [I said to her 'What am I to do?']

> 'Ma yeš?' le digo. *'Šš, givéret, ma at tsoéket!'*
> ['What's the matter?' I say to him. 'Sh, madam, what are you shouting about!']

It should be noted that this changing of code for direct quotation is not always mimetic; it does not always capture the code actually used by the original speaker.

Apparently simple repetition may gain added force from a change of code as in the extract below, where the London Jamaican version suggests that the speaker 'won't ever' go outside for air:

> I don't wanna go outside for fresh air, right, *mi na a go outsaid fa no fresh ier*
> (Sebba and Wootton 1984: 7)

Semantic contrast and balance in syntactic structure may be highlighted by having two focal sections of an utterance in different codes:

> *No vay ronto como iba pero* I still believe in it you know
> [I don't go as much as I used but …]
> (Pfaff 1979: 312)

The choice of code for each section may not be random, though it may be unconscious. It has been found, for example, that matters particularly associated with ethnic identity are often described or referred to in the code most strongly associated with that identity. Bentahila (1983: 235) describes the typical switch from French to Arabic when bilingual Moroccans mention matters to do with religion, and gives the following example:

> c'est une femme de marque qui est *f ši škl tmši tzur SSalhi:n*
> [she is a special woman who is the sort who goes to visit saints' tombs]

A switch from one language variety to another may index a particular socially significant factor, but it may not. Not all switches are linked to macro factors. Some simply serve as contextualisation cues, alerting the listener to a slight change in conversational activity, for example from narrating to commenting.

Humor can be achieved (or heightened) by a shift to another language or dialect if this triggers particular associations in the minds of the listeners. Sarcastic or ironic comment may also be delivered

in a contrasting code. Like several other writers whose readers are bilingual, Dangor takes advantage of the possibility of switching languages to heighten contrast in register. In the following extract from a short story, a character's bitter response to news that his lover is to be respectably married finds expression in the juxtaposition of a high register word in English with an obscenity in Afrikaans:

> And tomorrow you marry, medora on your head, your face veiled and hidden. Cossetted like a virgin, offered as noble sacrifice. And the willing smile on your face. Destiny Destiny!
> Destiny *se moer* [Literally, 'Destiny's womb']
>
> (Dangor 1981: 2)

Some kinds of code-switches seem to have more to do with linguistic factors than with stylistic effect of social context. They arise as a result of either a lexical gap in the language itself or in a speaker's vocabulary. It has been suggested that single loanwords may trigger a switch into a different language even when the rest of the utterance would have been equally possible in the first language, as in the following example of a switch from Arabic to French:

> ana maʕrftš fuqaš jži raši:d qalk l *weekend je ne sais pas quand est-ce que le weekend d'après lui*
> [I don't know when Rachid is coming: he said at the weekend. I don't know when the weekend is according to him.]
>
> (Bentahila 1983: 236)

With 'weekend' having become established in the French lexicon, and Arabic having no equivalent, this speaker inserts 'weekend' into an Arabic sentence and then continues in French. The first French phrase is clearly not an instance of filling a lexical gap as it is the equivalent of the opening Arabic phrase.

There are times when a switch may help cope with gaps that exist not in the language but in the speaker's vocabulary. Sometimes these are temporary gaps, resulting from an inability to recall a word in the language being used at the time, but able to recall it in another one. In such cases it is not uncommon to find that the speaker stays in the second code longer than is necessary to fill the lexical gap, as the following example shows: the repetition and voiced hesitation suggest a lexical gap in English for 'children'—a temporary gap, as a later stage of the conversation showed (McCormick 1990: 104) (see also *Bilingualism, Societal*; *Borrowing*):

> that is the day really a day of giving too because the the uh *kinders kom en hulle wil ook 'n stukkie eet nou*
> [...children come and they also want to eat a bit now ...]

3. Grammatical Analyses of Intrasentential Code-switching and the Theoretical Issues it Raises

Analysis of dense intrasentential code-switching is very challenging, particularly as there is often some phonological and syntactic convergence as well as lexical borrowing. This makes code boundaries difficult to identify. The example below is part of an adolescent boy's account of a wedding. He was a Panjabi speaker born and brought up in Leeds. (The text is given in phonetic script with the word by word translation immediately below each line.)

> sa:re ɟone otthe / ɔlukən si:z rɛd / geɔ aɔ/
> all people there / all you can see is red / get a
>
> wumən weərin rɛd su:ts / mus bi fe:vrɪt kulə / ʌnd
> women wearing red suits / must be favorite color / and
>
> ɟʌnɟ bunɖi otthe kotʃ ɟa:nɖa: / waef nu leke / tə
> marriage takes place there coach goes / wife having taken / and
>
> ɟɛlo pagz paidijā: / te otthe drunk hunɖa: fe:z /ʌn ðə we/
> yellow turbans wear / and there drunk gets then / on the way /
>
> sʌmtaim faʌɔs: /ma:r pi:pəl drink tu: mʌtʃ /ɪɔgaɔs in yuʌ had /
> sometimes fights /hit people drink too much /it gets in yours head /
>
> dʒʌs ha:pi ða de / ðaɔsɪɔðn /nɛks de brin ðə waif hie /
> just happy that day / that's it 'then /next day bring the wife here/
>
> avunðə pa:ɔi ən wi ɔl go ho:m /
> have another party and we all go home /
>
> (Agnihotri 1987: 129)

Intrasentential code-switching involving two (or more) languages is particularly interesting to syntacticians because it entails the interplay of grammatical rules from different systems and the rules for the formation of some structures may be incompatible. For example, the Spanish and English rules for the placement of adjectives in a noun phrase are diammetrically opposed: the Spanish rule places almost all adjectives after the noun whereas the English rule places them before the noun. How do fluent Spanish–English code-switchers construct a noun phrase that contains an adjective? Do they avoid switching within the NP or do they make a choice which violates the rule of one of the languages? Although lay people often judge code-switching to be both a product and a sign of linguistic incompetence, early analyses of fluent conversational code-switching data yielded little evidence of ungrammaticality. This led linguists to believe that there might be grammatical constraints on where switches could take place—the operation of these constraints would prevent the formation of ungrammatical strings. Later analysts, who detected nonstandard but regularly occurring structures composed of elements from two languages, argued that fluent, dense code-switching might affect the grammar of either or both dialects, causing them to converge.

Research on the grammatical aspect of code-switching can be seen as falling into four broad types, depending on the researcher's prime concern

(though in most projects there are traces of one or more of the other types). They examine: language-specific constraints; the possible existence of universal constraints; the requirements of a model of grammar that would best capture the rules of code-switching; the validity of the assumptions underlying research into grammatical constraints on code-switching.

Much of the work done in the 1970s was directed towards finding evidence of nonrandomness in morphosyntactic aspects of code-switching. Studies tried to identify the rules which disallowed switching at particular junctures. Reports of the findings often included lists of several rules governing particular structures. The data for these early studies usually came from particular bilingual situations—the studies were not comparative. The constraints identified were thus language-specific though sometimes the wording suggested that they were general.

In 1980, Poplack (see *Poplack, Shana*) suggested that two constraints might be universal. They were the 'free morpheme constraint' and the 'equivalence constraint,' which she defined as follows:

The free morpheme constraint. Codes may be switched after any constituent in discourse provided that constituent is not a bound morpheme. This constraint holds true for all linguistic levels but the phonological (p. 587). **The equivalence constraint.** Code-switches will tend to occur at points in discourse where juxtaposition of L1 and L2 elements does not violate a syntactic rule of either language, i.e., at points around which the surface structures of the two languages map onto each other p. 586).

These hypothesized universals were regarded with great interest and in the early 1980s their applicability to various sets of data was tested. Studies of other Spanish–English data seemed to validate the constraints, but the universality of the equivalence constraint was found not to hold in cases of switching between languages less similar to each other than English and Spanish, for example Arabic/French and Spanish/Hebrew. The free morpheme constraint, on the other hand, did hold.

Closely related to the work on grammatical constraints were attempts to find a model for a grammar which would be able to account for rule-governed code-switching. The necessity of positing a 'third grammar,' a grammar of switching was considered, as was the possibility that rule-governed switching could be adequately accounted for on the basis of the rules of the two contributing languages. Pfaff (1979) thought there was no need to argue for a third grammar, whereas Poplack, a year later, suggested that code-switching might emanate from 'a single code-switching grammar composed of the overlapping sectors of the grammars of L1 and L2' (1980: 615). Sankoff and Poplack (1981) developed that idea by suggesting that a 'third grammar' could subsume the two monolingual grammars, thus providing a single framework within which discourse characterized by dense code-switching could be analyzed. Romaine argued that a third grammar might not simply draw two monolingual grammars into one framework, but might have to be what she called a 'convergent grammar' because it was possible that 'the internal structure of the mixed constituent need not conform to the constituent structure rules required for monolingual grammars of either language' (Ms n.d.: 27).

An alternative to positing the existence of a third grammar, was the suggestion that rule-governed switching could be accounted for by the modification of existing frameworks (see *Code-switching: Structural Models*). Models of grammar that had been developed to account for monolingual structures were explored and compared for their capacity to be extended to cover bilingual structures. For example, Di Sciullo et al. (1986: 23) claim that:

the general restrictions on code-mixing need not be stated anywhere, but arise from general conventions of language indexing.

Analysis of the grammaticality of utterances containing a code-switch depends on identifying the switch point in an utterance, and, where there has been convergence between the two codes, this identification is not a simple matter. It generates a series of questions that have important implications for other fields of linguistics. Work on dense code-switching has brought to the fore problems about the often *ad hoc* way in which, in practice, words are categorized as belonging to one language or another. From what might be called a 'systems perspective' (based on knowledge of the set of structures and the lexicon said to constitute a particular language), a word might seem to belong to Language A and be a foreign import in Language B, because the historical roots of the word are known to the analyst doing the categorizing. But what of the speaker's perspective? What if the speaker does not know that a particular word is a loanword, should it necessarily be regarded as one? If the word in question is at the juncture between phrases in two codes, to which should it be said to belong? If one takes a long historical perspective, a large part of the vocabulary of many languages could be said to consist of loanwords. All languages change. What should the criteria be for categorizing what was once a loanword as an established item in the receiving language's lexicon? Length of time over which it has appeared in the receiving language? Frequency of use, and if so, use by whom—formally educated speakers? Speakers' awareness of the word's origin, and if so, which speakers? Coexistence with or replacement of

452

equivalent item in the receiving language? Morphological or phonological adaptation to the system of the receiving language?

If it is difficult to give clearcut answers to these questions when two languages are involved, it is even more difficult to answer them when dealing with switches between two dialects or styles. In the case of dialect or style switching there is a far larger proportion of the vocabulary and other linguistic features common to both codes, and systematic descriptions of both codes are seldom available for use as points of reference. In such cases analysts have to rely more heavily on their (or their subjects') intuitions about what constitutes each of the codes juxtaposed in the switch. But if code-switching between languages and between dialects serves similar stylistic and social purposes, should the analysis not deal with them in the same way, giving equal weight to systems or to speakers? It has recently been argued (Auer 1998: 13) that the speaker's perspective should carry more weight than the linguist's in determining what constitutes a code or an instance of code-switching. This approach makes it possible to conceive of a bilingual code. It allows for dense switching between two language varieties to be regarded as one code in cases where such switching functions as one code for its users (see *Code-switching: Discourse Models*). In much early research the term 'code' was assumed to be synonymous with 'language variety' and it was thus assumed that alternation of language varieties constituted code-switching. The assumed synonymity has recently been questioned. Different perspectives generate different analytic models and tools which illuminate different aspects of the data. In doing lexical and syntactic analyses of dense code-switching linguists might benefit from the example of physicists who find it productive to analyze light as both waves and particles, although these two models might appear to be irreconcilable. Some contemporary work explores the productiveness of using both speaker's and linguist's perspectives on what constitutes a code and a code-switch in a particular speech community's repertoire.

4. Code-switching: Deficit or Skill?

When code-switching is discussed the question of speakers' competence is frequently raised: are code-switching and linguistic competence mutually exclusive? Because it is popularly believed that switching is a result of incompetence rather than of a fine sense of the unique effects that it can achieve, switching is often stigmatized. People say that those who switch 'can't speak properly' or 'make a mess' of the languages they use.

On closer examination it appears that two types of switching are differently regarded. Whereas diglossic and situational code-switching are often regarded as

necessary manifestations of bilingualism, and are valued as part of a speaker's communicative competence, conversational switching is often overtly stigmatized. Covertly it may be valued for its rhetorical possibilities and as a group-marker. The crucial linguistic difference between the two types of switching that probably accounts for this difference in attitude is that situational switching involves the production and comprehension of long strings in each language, so fluency is apparent, whereas in conversational code-switching the switch is frequently intrasentential, allowing for an impression that speakers are insufficiently proficient in either language to be able to finish what they want to say, in one language.

A common assumption is that people switch languages because of gaps in their personal vocabulary. As is shown in examples cited above, this is true in some cases but not in others. The study of a large corpus of data from a member of a bilingual, code-switching community will often show the speaker using the words for a concept from both languages. Witty, quick, elegant shifts between codes are often appreciated in the speech community. Proficient bilinguals or bidialectals who switch codes consciously or unconsciously achieve particular social, political, or rhetorical effects. They are able to draw on a bigger linguistic pool than they would be if they and their interlocutors were monodialectal or monolingual.

> Code switching is a communicative skill, which speakers use as a verbal strategy in much the same way that skillful writers switch styles in a short story.
> (Gumperz and Hernandez-Chavez 1972: 98)

Code-switching: Sociopragmatic Models

S. Gross

In many bi- and multilingual communities around the world, speakers need to choose, often at an unconscious level, which language to use in their interactions with other members of the community. One of the choices that bilingual speakers often make is to code-switch; that is, speakers switch back and forth between languages, even within the same utterance. The research question that sociolinguists have been seeking an answer for is why speakers choose to engage in code switching.

1. The Advent of Code-switching Research

Perhaps the earliest attempt to address the question of why speakers code switch was Blom and Gumperz's (1972) study of language use in Hemnesberget, a small village in northern Norway. In Hemnesberget, two varieties of Norwegian are used: Ranamål, a local dialect, and Bokmål, the standard variety (see *Dialect and Dialectology*). However, the speakers' decisions regarding which variety to use is in no sense arbitrary or haphazard. Blom and Gumperz report that the villagers use these two varieties on different occasions largely because of the different social meanings they fulfill. Ranamål is used for locally based activities and relationships reflecting shared identities with the local culture. In contrast, Bokmål is used in official activities, such as school, church, and mass media, communicating an individual's dissociation from the local group.

Blom and Gumperz observed that in the villagers' conversations, switching from one variety to the other might occur in response to a number of factors. For example, when an outsider joins a group of locals engaged in a conversation, the locals will often shift from Ranamål to Bokmål. This type of shift, occasioned by a change in participants, is referred to as 'situational' code-switching. A more complex type of code-switching that occurs in response to a change in topic is termed 'metaphorical' code-switching. The classic example of metaphorical code-switching is of a conversation at the local community administration office, where two villagers switch from the standard variety of Norwegian, in which they have been discussing official business, to the local variety to discuss family and other private affairs.

Blom and Gumperz's study is important because it illustrated that code-switching is a complex, skilled linguistic strategy used by bilinguals to convey important social messages above and beyond the referential content of an utterance. In addition, this study sparked an interest in studying code-switching data in terms of a dynamic, interactional model that focuses on individual choices rather than static factors related to an individual's social status (see *Social Class*).

2. The Audience Centered Approach to Code-switching

Howard Giles and his associates have developed a model of interpersonal communication that considers how speakers change the way they speak according to their audience. Giles refers to this type of strategy as accommodation (see *Audience Design; Speech Accommodation*). Within Giles' speech accommodation theory, speakers are motivated by their desire for approval vis-à-vis their desire to dissociate themselves from the hearer. These concerns are cognitively salient and are realized by speech convergence (similar styles of speaking) or divergence (different styles of speaking). Thus, convergence and divergence are linguistic strategies to either decrease or increase communicative distance.

Although the premises behind speech accommodation theory have not been tested using code-switching data in any comprehensive way, it is not difficult to see how the model could be used to explain the motivations for code-switching. For example, in an experiment testing the divergence aspect of speech accommodation theory, Bourhis et al. (1979) tried to get at the social meaning behind the code-switching behavior among Flemish–French bilinguals in their interactions with French speakers in Belgium. The researchers found that the Flemish-speaking participants in the experiment viewed a switch to Flemish as a strategy for expressing disagreement with French speakers.

Speech accommodation theory has been successfully applied mainly in contexts of dialect or style switching. However, the theory and its predictions still await further testing on code-switching in bilingual settings.

3. The Markedness Model: A Speaker Centered Approach to Code-switching

One of the most highly developed models designed to explain the sociopragmatic motivation for code-switching is Carol Myers-Scotton's markedness model, which developed out of her field research in East Africa. The central premise of the markedness model is that speakers are rational actors who make code selections in such a way as to minimize costs and maximize rewards; that is, speakers are concerned with optimizing the outcomes of an interaction in their own favor.

This notion of the speaker as a rational actor is also evident in speech accommodation theory as well as Gumperz's interactional approach to code-switching. However, unlike these other models, which consign the primary motivation for code-switching to the addressee or to some other factor external to the speaker (e.g., topic or social setting), the markedness model is primarily a speaker-centered approach to communication.

4. Markedness and Communicative Competence

Within the markedness model, all code choices fall along a continuum as more or less 'marked' or 'unmarked.' The unmarked choice simply refers to the linguistic variety that is expected, given the societal norms for that interaction. In contrast, marked choices fall at the other end of this continuum; that is, they are in some sense unusual or unexpected for the particular social interaction.

Furthermore, all speakers possess what Myers-Scotton calls a markedness evaluator, or the capacity to evaluate linguistic choices in terms of markedness, as part of their innate communicative competence (see *Communicative Competence*). While the capacity to assign markedness readings to linguistic choices is innate, the markedness continuum is established through exposure to the different options used in the community.

5. Explaining Speakers' Choices

All code choices can ultimately be explained in terms of speakers' motivations to optimize the outcomes of the interaction for themselves. Most choices that speakers make affirm the norms that are in place for a particular exchange. These are unmarked choices, and they are usually the safest choices to make. The particular code used by the speaker is important only insofar as the participants view its status as marked or unmarked for that type of interaction. Thus, in a multilingual setting such as Nairobi, Kenya, the unmarked choice for most business transactions between strangers is Swahili. For example, if the participants discover during the course of their interaction that they are members of the Luyia ethnic group they will often switch into Luyia to continue the conversation. Luyia, then, becomes the unmarked choice. However, code-switching between Swahili and English within the same turn, within the same sentence, and even within words is typically the unmarked choice for informal social gatherings between educated, middle class peers. Hence, the markedness of linguistic choices must be evaluated in terms of the norms for a particular exchange; the unmarked setting may even change within the same conversation.

In contrast to the safety of unmarked choices, marked choices carry with them some element of risk for someone who wishes to defy the norms. Importantly, the interpretation that a marked choice receives derives from its contrast with the unmarked choice for that particular interaction. That is, the unexpectedness, the 'otherness' of a marked choice carries significant social meaning. Marked choices are typically used to redefine the relationship between the speaker and addressee, often as an expression of the speaker's authority or power, to indicate anger, or to assert one's ethnic identity (see *Identity and*

Language; *Power and Language*). All these strategies can be subsumed under a single general principle: speakers make marked choices to negotiate a change in the expected social distance between the participants, either increasing or decreasing it.

6. The Significance of the Markedness Model

Since its formalization, the markedness model has been successfully used to explain code-switching between languages, between dialects and registers, and even between stylistic choices in literary contexts. The strength of the markedness model is its ability to explain not only unmarked choices, which most other models do as well, but also its ability to explain marked choices. Furthermore, the markedness model addresses the universal aspects of communicative competence in terms of cognitive abilities to use readings of markedness to assess speakers' intentions. For these reasons, the markedness model is a powerful tool not only for code-switching research, but also for any examination of the ways in which speakers use language to achieve their interactional goals.

Code-switching: Structural Models
R. M. Bhatt

1. Introduction

One of the most pervasive phenomena of bilingual behavior is code-switching, the ability of bilinguals to switch back and forth between the languages they control, exemplified most strikingly in the title of Poplack's (1980) paper, 'Sometimes I'll start a sentence in Spanish y termino en español.' The assumption guiding much of the research in code-switching is that different languages in the bilingual's verbal repertoire are not kept hermetically in sealed boxes; their mutual spillover and influence provide useful clues to our understanding of bilinguals' language use, acquisition, and change (see Bhatia and Ritchie 1996, Muysken 2000). This entry focuses on research that deals with the structural design of code-switching, the knowledge and ability underlying bilinguals' use of two languages within a sentence. This ability known variously as 'code-mixing' (see *Code-mixing*), or 'intra-sentential code-switching' is illustrated in the Hindi-English code-switching examples below. As in the case of modern syntax, it is important to consider unacceptable switches (marked with a *) as much as actually occurring and acceptable switches.

(1a) aapkii *sister* aajkal kyaa paRhaatii hai
      your these days what teaches is
      'What does your sister teach these days?'

(1b) *your* behan aajkal kyaa paRhaatii hai
      sister these days what teaches is
      'What does your sister teach these days?'

(2a) Suresh bought flowers apnii behan ke liye
      his sister for
      'Suresh bought flowers for his sister.'

(2b) *Suresh bought flowers for apnii behan
      his sister
      'Suresh bought flowers for his sister.'

The research output in the 1980s in the area of structural constraints on code-switching has challenged the claim in the earlier sociolinguistic literature that code-switching is random (e.g., Labov 1971: 457, Lance 1975: 143), and instead put forward the view that code-switching is systematic and rule-governed. As such, these studies introduced, inductively, several structural (syntactic) constraints to account for cross-linguistic generalizations of code-switching. Relatively recently, however, attempts have been made to ground the syntactic constraints in formal linguistic theories to account for what Ferguson (1978) called the 'bilingual's grammar.' Inquiries into the structure of the bilingual grammar has been rationalized by the fact that code-switching is automatic, and the fact that fluent bilinguals have

fairly consistent judgments on the well-formedness of code-switched sentences (cf. Singh 1985).

2. Bilingual's Grammar: Earlier Proposals

Some of the earliest attempts toward structuring code-switching resulted in descriptive generalizations, encoded as language-specific constraints. Kachru (1978), for instance, proposed the following surface syntactic constraints in Hindi-English code-switching: (a) the 'Determiner Constraint,' banning switching of the determiner (see, e.g., examples (1) and (2) in Sect. 1); (b) the 'Conjunction Constraint,' requiring the conjunction to belong to the same language as the second conjunct, correctly predicting the ill-formedness of expressions like *John aayaa ('came') *nahiiN* ('not') *lekin* ('but') *I must wait for him* 'John hasn't come but I must wait for him'; and (c) the 'Complementizer Constraint,' requiring the complementizer to belong to the language of the matrix clause, correctly predicting the illformedness of expressions like **mujhe lagtaa hai that John will come tomorrow* 'I think that John will come tomorrow.' The bulk of research on structural constraints on code-switching in the 1980s was, however, done on Spanish-English, two languages that share several surface structural properties. Poplack (1980), following Lipski (1977) and Pfaff (1979), proposed two constraints that seemed at once general enough and restrictive enough to be able to account for all-and-only instances of Spanish-English code-switching. The first constraint is the 'Free Morpheme Constraint,' which bans switching of bound morphemes, as shown by the ungrammaticality of (3) below.

(3) *Estoy   *eat*-iendo
     am   eat-ING
     'I am eating.'

The second constraint, the 'Equivalence Constraint,' which has received the most attention in the code-switching literature (see also Muysken 2000), permits code-switching only at points where the surface structure of the two languages map onto each other. This constraint correctly predicts the grammaticality contrast in (4) below: (4a) is acceptable (Lipski 1977) because the grammars of English and Spanish coincide, but (4b) is unacceptable because the two grammars differ with respect to the placement of the object pronoun (Spanish requiring an object pronoun before the verb, unlike English).

(4a) Tonces salio eso que   *she wanted to take mechanics*
      'It turned out that she wanted to take mechanics.'

(4b) *I   saw   *lo*
                    it
      'I saw it.'

Sridhar and Sridhar (1980) extended the empirical scope of the Equivalence Constraint by proposing the 'Dual Structure Principle' to account for Kannada-English code-switching of the type given in (5) below, where the switched constituent of the 'guest' language, English, does not violate the linear precedence rules of the 'host' language, Kannada.

(5) nanna abhipraayadalli *his visiting her at home* sariyalla
     my   opinion-in   proper-not

     'In my opinion, his visiting her at home is not proper.'

Sridhar and Sridhar thus introduced a conceptualization of code-switching where the participating languages were assumed to have asymmetric roles: the host language provides the constituent structure of the entire code-switched utterance and the guest language provides elements into the host language. Later works on code-switching took this asymmetric relationship between participating languages as axiomatic.

Another important contribution to the literature on structural constraints in code-switching came from the work of Aravind Joshi (1985). He observed that closed class items, e.g., determiners, quantifiers, prepositions, possessive, Aux, Tense, helping verbs, etc., were most recalcitrant to switching. His 'Closed Class Constraint' formalizes his observation. Later works of Myers-Scotton (1993) and Belazi et al. (1994) make extensive use of his insight.

3. Code-switching in Generative Grammar

Although most of the constraints proposed were able to capture the descriptive generalizations of code-switching for specific language pairs, they invariably failed to generalize, because of their structural design, beyond the data-sets for which they were proposed (see Bokamba 1989, Clyne 1987). The real challenge then was to couch the proposals in generative grammatical theory so that theoretical models of code-switching could be developed, ones that made claims about the bilingual's language competence. The methodologically plausible goal of such an enterprise was to spell out, in some detail, the elaborate and abstract computations, the formal principles, that make possible the creative aspect of bilingual's language use, code-switching.

One significant beginning, after Woolford's (1983) and Bentahila and Davies' (1983) initial attempts, was the 'Government Constraint' proposed by Di Sciullo et al. (1986), elaborated later by Halmari (1997) and Muysken (2000). This constraint bans code-switching at a structural position, which is governed (by a head like a verb or a preposition). The grammaticality contrast in (6) below illustrates how their constraint works. (6a) is the grammatical option

because the V(erb), with language index E(nglish), governs, and therefore requires, the specifier (*your*) of the object NP to carry the same language index, which it does. (6b), on the other hand, is the ungrammatical option because the specifier (*tumhaarii*) of the object NP does not carry the language index of the verb, resulting in the violation of the Government Constraint.

(6a)   I heard your *burii khabar* today
                      bad news

        'I heard your bad news today.'

(6b)   *I heard *tumhaarii burii khabar* today
                your   bad news

        'I heard your bad news today.'

Although this constraint correctly predicts the contrasts noted above in (1), (2), (4), and (6), several counterexamples of it are reported in the literature (see Belazi et al. 1994, Bhatia 1989).

In the 1990s, the use of grammatical theory to account for code-switching became the received methodology. Mahootian (1993), for example, uses a computationally-based formalism, the Tree Adjoining Grammar, to account for Farsi-English code-switching. Her analysis, essentially following Pandit's (1990) insight, is based on the assumption that in code-switching the language of the head determines the syntactic properties of its complement. Her analysis is unable to account for the ungrammaticality of (2b) and (6b) in Sect. 1: neither the switched complement of the prepositional phrase in (2b) violates the properties of the head (preposition) nor the switched complement of the verb phrase in (6b) violates the properties of the head (verb). In her theory, therefore, both (2b) and (6b) are incorrectly predicted to be grammatical code-switches (see also Bhatt 1997a).

Myers-Scotton (1993) uses a combination of production mechanisms and aspects of grammatical theory to propose her Matrix Language Frame (MLF) Model of code-switching. The model is built on two central hierarchies: the matrix language (ML) vs. embedded language (EL) distinction and the content vs. system morpheme distinction. These oppositions yield the Morpheme Order Principle and the System Morpheme Principle, which, taken together, state that morpheme order and all syntactically-relevant system morphemes in mixed (ML + EL) constituents will come from the ML. This model has several theoretical, methodological, and empirical problems, as pointed out, among others, by Bentahila (1995).

The MLF model is now augmented with two sub-models: the 4-M model and the Abstract Level model. The major innovation in the new version is

that now there are four, not two, different types of morphemes (content morphemes vs. three types of ['early,' 'bridge' and 'late'] system morphemes) available at different levels of grammatical organization and activated and combined by different mechanisms in production (for details see Myers-Scotton and Jake 2000).

Two other proposals advanced recently— Belazi et al. (1994) and MacSwan (1999)—use the 'Minimalist' (Chomsky 1995) technology to account for bilingual code-switching. These accounts presuppose familiarity with the most recent version of Chomskyan syntax and is not easy to summarize in the space available. Essentially, Belazi et al. proposed the 'Functional Head Constraint,' stated as: 'The language feature of the complement f-selected by a functional head, like all other relevant features, must match the corresponding feature of the functional head.' This constraint is thus designed to ban switching between functional heads (e.g., C(complementizers), Infl(ection), D(eterminers)) and their corresponding complements (e.g., IP = (S), VP, NP). Thus, in their theory, they extend the feature 'checking domain' (à la Chomsky 1995) of functional heads to include 'internal domains.' The idea is simple, yet attractive—that functional heads engage in checking not only the properties of their specifiers, but also the properties of their complements. Assuming, especially in bilingual language use, 'language' to belong to the set of morphological features that needs to be checked off for licit derivation, it follows that code-switching will be disallowed only in those instances where there is a mismatch between a functional head and its complement in the language feature, which yields an illicit derivation. Although theoretically attractive, their proposal makes false predictions (see Bhatt 1997b, Mahootian and Santorini 1996). [Abbreviations: NP—noun phrase; IP—inflection phrase; S—sentence; VP—verb phrase.]

MacSwan (1999) carefully accounts for Nahuatl-Spanish code-switching purely on Minimalist assumptions (Chomsky 1995). A Minimalist account, however, does not block the derivations of (1b) and (2b), since neither the structure-building operations (Merge, Move) nor any Checking (Case, EPP), Computational (Last Resort, Minimal Link Condition), or Economy (Full Interpretation, Procrastinate, Shortest Derivation Condition) principles are violated by the switched items in these examples. The data in (1b), for example, is both LF and PF convergent. There are no special lexical requirements of the Hindi subject DP that would lead the derivation to crash: the nominative (phonologically null) Case of the (Hindi) Subject DP, sitting in Spec-TP, is checked by T. In other words, an account of variation in code-switching remains problematic under strict Minimalist interpretation of generative

grammatical theory. [Abbreviations: DP—determiner phrase; LF—logical form; T—tense; TP—tense phrase; PF—phonetic form.]

4. Code-switching, Language Variation, and Optimal Grammars

In order to account for language variation in code-switching, Bhatt (1997a) proposes an optimality-theoretic (OT) account of the phenomena. In OT (Prince and Smolensky 1993), Universal Grammar is conceptualized as a set of potentially conflicting constraints holding in all languages, with cross-linguistic variation arising from the fact that different languages resolve the conflicts among these constraints differently. This framework thus holds promise for a theory of code-switching by recruiting structural constraints proposed for different pairs of languages and allowing them all to interact to account for cross-linguistic generalization.

Bhatt (1997a, 2001) argues that the constraints offered in the past to express distributional generalizations of code-switching were categorical: their violations lead to illicit structures. Instead of using categorical constraints, a slight adjustment in the theory—from inviolable to 'violable' (soft) constraints—yields the relevant generalizations. These soft constraints are violable in just those contexts in which they conflict with a higher ranked constraint. The claim, then, is that a code-switched constituent that violates a particular constraint has its well-formedness 'reduced' by a certain amount (cf. also Singh 1985).

Bhatt (1997a) begins with the observation that languages involved in code-switching have 'preferences' for what counts as 'well-formed.' This cross-linguistic observation affords the plausible assumption that the syntax of code-switched constructions strives toward well-formedness, i.e., when the guest (embedded) constituents are mixed into the host (matrix) language, the syntax operates to optimize well-formedness. In other words, when the guest items are introduced to the host language, certain adjustments follow, naturally, since items (words, phrases) from one language with one set of well-formedness conditions move to a language with another set of well-formedness conditions.

The constraints recruited in Bhatt (1997a, 2001) are universal; they have appeared in the literature in different guises and under different names, either in the form of concrete proposals or in the form of background assumptions. Thus, the 'Head Syntax Constraint'—the grammatical properties of the language of the head are respected within its 'minimal domain'—is a synthesis of Mahootian (1993), Pandit (1990), and Sridhar and Sridhar (1980). Similarly, the 'Linear Precedence Con-

straint'—the order of the arguments of the verb must follow the requirements of the language of Infl—is a reformulation of Myers-Scotton's (1993) Matrix Language Hypothesis. The 'EQUI Constraint'—maximizing harmony in code-switching when the well-formedness conditions of the switched items are met—is a reformulation of Pfaff (1979), Poplack (1980), and Sridhar and Sridhar (1980). The Specifier Constraint—the Specifier of an XP must be of the same language as the head which assigns Case to that XP—is discussed in Joshi (1985), Kachru (1978), and Singh (1985). Finally, the Complaisance Constraint—if Spec-XP switches then head X switches too—is a fidelity constraint, discussed by Backus (1992). Although these constraints are, consistent with the logic of Optimality Theory, universal, the effect of the presence or nonpresence of a constraint in code-switching is more a matter of its ranking relative to other constraints in a particular bilingual grammar. The cross-linguistic variation in code-switching arises from different constraint-ranking configurations opted for by different bilingual grammars. [Abbreviations: Infl—inflection; Spec—specifier.]

Although it is not possible here to present a detailed exposition of the optimality account of code-switching, it suffices to say that even subtle contrasts, noted in English-Hindi (7) and Spanish-English (8) code-switching, that do not compartmentalize neatly into grammatical-ungrammatical distinctions are also easily explained as a result of constraint interaction and satisfaction, as outlined in Optimality Theory. In both examples (7) and (8), the (a) options are the best code-switches, followed by (b) which appears slightly degraded compared to (a). The (c) options (marked*) are absolutely unacceptable.

(7a) √Ramesh bought an expensive watch *apne bhaaii ke liye*
                                         his brother for

     'Ramesh bought an expensive watch for his brother.'

(7b) ?Ramesh bought an expensive watch *apne* brother *ke liye*
                                        his   for

(7c) *Ramesh bought an expensive watch his brother *ke liye*
                                                for

(8a) √I saw *la casa*
         the house

(8b) ?I saw the   *casa*
                    house

(8c) *I saw *la*   house
          the

These subtle contrasts are captured straightforwardly by the interaction and satisfaction of two constraints, *SPEC and COMP: the grammar of English-Hindi

code-switching yields the contrast by ranking *SPEC over COMP and the grammar of Spanish-English code-switching yields the contrast by ranking COMP over *SPEC (see Bhatt 2001, for details).

The claim, then, is that the patterns of code-switching, as in (1)–(8) above, emerge from the interactions of structural constraints—the optimal adjustment between items of the two languages yielding the grammatical option. Given an OT perspective, the grammatical differences between different code-switching grammars are reduced to the different constraint rankings each grammar chooses.

5. Conclusions

Studies on structural constraints on code-switching have, over the years, attempted to systematize the linguistically significant generalizations of bilinguals' language use. Although these accounts have become increasingly theoretically sophisticated, insofar as they present optimism for speculations on the bilingual mind design, they are, unfortunately, based on the methodological premise that constraints are infallible. This leads to the familiar predicament that the predictions are not borne out when tested across different pairs of code-switching languages. Further progress in our understanding of bilinguals' grammar can perhaps be made with a slight conceptual shift—that generative grammar defines a set of violable constraints, prioritized in language-specific ways. The observed syntactic differences among languages involved in code-switching will then turn out to be different constraint-ranking configurations opted for by different bilingual grammars.

Contact Languages

S. G. Thomason

Three types of new language arise from contact: pidgins, creoles, and bilingual mixed languages. Each of these types emerges under social conditions that are relatively unusual. Pidgins are the most common type by far, followed by creoles and then, a distant third, bilingual mixed languages. Structural and historical generalizations about pidgins and creoles are drawn primarily from the results of intensive research over the past four decades. In spite of the large and growing body of data on these contact languages, however, virtually every theoretical proposal about the nature and origin of pidgins and creoles is controversial. The situation is different with stable bilingual mixed languages: so few of them have been sufficiently well documented and systematically investigated that generalizing about them is probably premature. Below is a sketch of each type, together with brief indications of a few of the major controversies surrounding them.

The typical pidgin (see *Pidgins and Creoles: An Overview*) is created in a new contact situation involving two or more (almost always more) languages when a medium of communication is needed for use in limited social contexts, for instance trade. The groups in contact retain their respective native languages, and they do not learn the other groups' languages. A certain amount of time is obviously required, at least a few years—the exact amount of time is unknown, because the process has never been observed—before the emerging contact medium *crystallizes* into a pidgin language, with its own lexicon and grammar that must be learned by new speakers. Some scholars refer to the formative stage(s) of pidgin genesis as *pre-pidgin* or *jargon* (see *Jargons*) stage(s). The lexicon comes primarily (up to ca. 90 percent) from one of the languages in the contact situation, the *lexifier language*. The grammar, however, comes neither from that language nor from any other single language. Its sources are a matter of

controversy; the two major contenders are cross-language compromise and simplification by all speakers of their native languages until they end up with a set of maximally simple structures. A third view, which used to be more popular than it is now, is that pidgin structures are derived from simplification of the lexifier language alone, by its own speakers and also by others who are creating the contact language. The main reason this view is no longer widely held is that a great many pidgins have structures that demonstrably cannot be derived, by simplification or any other means, from the lexifier language—such as the inflectional categories of dual and trial number and inclusive vs. exclusive 'we' in the pronominal system of Tok Pisin, an English-lexifier pidgin that is now one of the official languages of Papua New Guinea.

Thanks, apparently, to the limited functions fulfilled by a typical new pidgin, its linguistic systems are also limited. The lexicon is small relative to the lexicon of other natural languages, stylistic registers are limited or nonexistent, there are relatively few complex sentence structures, and there is relatively little morphology or, in many cases, none at all. Typical examples of trade pidgins include Chinook Jargon, once spoken from northern California to Alaska in the US and Canada, and Chinese Pidgin Russian, once spoken along the Russo-Chinese border. In some pidgin genesis contexts, speakers of the lexifier language deliberately withhold their full language so that outsiders (e.g., trading partners or slaves) cannot learn it; instead, they use a simplified version of their native language, which then becomes the lexifier of the new pidgin. An example is Hiri Motu, one of the three official languages of Papua New Guinea, which crystallized after it was designated as the language of the ethnically diverse police force that was established by British colonial authorities late in the nineteenth century.

461

One theory of pidgin structure, mentioned above, is that pidgins are maximally simple—that their structures reflect, and perhaps even provide evidence for, universally unmarked structural features. There are several weaknesses in this view. In particular, pidgins are by no means all alike; many pidgins have at least a few universally marked features (for instance the Tok Pisin pronominal categories or the elaborate, consistent, and highly marked consonant inventory of Chinook Jargon); and some pidgins have morphological structures that are by no means candidates for unmarked status. Most other controversies about pidgins parallel some of the creole controversies (see *Pidgins and Creoles: Models*), which tend to be more heated (and often, in fact, to provide more heat than light).

Like pidgins, creoles develop in contact situations where two or more (almost always more) languages are spoken by groups whose members do not learn each other's languages. Also like pidgins, creoles are mixed languages in the strong historical linguist's sense: their lexicon and structure do not come primarily from the same source language. As with pidgins, the lexicon comes primarily (up to ca. 90 percent) from one language, but the grammar comes from no single language. Unlike the typical pidgin, the typical creole serves as the (or a) main language of a speech community. Neither its social functions nor its structures are limited in any way.

Creoles seem to have arisen in at least three different ways. First, some pidgins have turned into creoles, through functional and structural expansion and eventual *nativization* (so that they are learned as first languages by the community's children). Tok Pisin is a prime example: it apparently began—somewhere in the Pacific, though perhaps not in New Guinea itself—as a trade pidgin; its uses in New Guinea expanded beyond trade into a wide and increasing variety of social functions, and its lexicon and grammatical resources expanded along with its functions, until eventually it became a creole.

Second, some creoles apparently emerged abruptly, without going through a stable pidgin stage. This would happen in a new contact situation where, for some reason, the various groups of speakers cannot continue to use their respective native languages. The adults' initial mode of communication in such a case would perhaps be a pre-pidgin, but not a fully crystallized pidgin language, because the new contact medium would be required for all social interaction, they and their children—the relative amounts of input from adults and children is disputed—would create an *abrupt creole*. It was once thought that this scenario fit most or all creoles that arose as a result of the Atlantic slave trade, on the assumption that newly enslaved Africans could not, or would not, learn the slavemasters' languages and could not retain their native languages (see e.g., Alleyne 1971). This scenario is no longer attractive, in part because we now know that in many Caribbean colonies people did continue using their native languages (so that a crystallized pidgin stage was both possible and likely). But there are still a few plausible candidates for abrupt creole genesis, for instance Hawaiian Creole English (see e.g., Bickerton 1999: 51ff.) and Pitcairnese, the creole that developed after 1790 when the nine *Bounty* mutineers settled on Pitcairn Island with their mostly Tahitian companions. According to Bickerton's Language Bioprogram Hypothesis, children born into a new multilingual community develop specific proposed structures that are argued to be universal in abrupt creoles, to account for the creation of an abrupt creole. His view continues to be controversial and is currently more popular among specialists in language acquisition and formal syntactic theory than among creolists. A rival current theory of abrupt creole genesis is that the structures of abrupt creoles, like those of new pidgins, derive from cross-language compromise among the languages of their creators, through a process that has been called 'negotiation' (Thomason 2001: 180–2, Thomason and Kaufman 1988: chaps. 6–7). On this view, the genesis of both pidgins and abrupt creoles can be usefully compared to shift-induced interference—that is, to imperfect second language acquisition—although the analogy is far from complete. The general approach is traditionally referred to in the literature as the *substrate theory* (see e.g., Boretzky 1983, Holm 1988–1989; see *Language Transfer and Substrates*), and in current theories it is usually integrated with markedness-based universalist considerations (see e.g., Thomason and Kaufman 1988: chaps. 6–7).

The third route to creole genesis is not merely comparable to shift-induced interference, but is actually shift-induced interference. On this view, proposed most prominently by Chaudenson (e.g., 1992) for French-lexifier creoles, creoles emerge through a gradual process of repeated instances of group second-language acquisition, with shift-induced interference at each stage accumulating until the result is a creole language, too distant linguistically to be considered a dialect of the lexifier language that provided the original target for language learning. The social circumstances under which the process began involved small farms with roughly equal numbers of French speakers and African slaves who learned French; the farms were eventually succeeded by large plantations, with each wave of newly imported slaves learning the plantation's lingua franca from earlier

slaves. Reunionese, the French-lexifier creole of Reunion, has been proposed as a prime example of a language that arose in this way, and it is possible that some Caribbean creoles also followed this route—although it has also been argued, e.g., in Singler (1996), that the change from small farm to large plantation was too abrupt in certain Caribbean colonies to accommodate a steady gradual process involving successive influxes of large new groups of slaves.

Most specialists do not believe that creoles can be characterized by a 'laundry list' of linguistic features, in spite of the fact that most of them share with most pidgins (sometimes, of course, because they have arisen through nativization of a pidgin) an analytic structure with relatively little morphology, and also a relatively simple phonological system. Earlier investigators believed in a laundry-list approach to identifying creoles ('if the language has this set of features, it must be a creole'), but the view fell out of favor when the most-studied creoles, those spoken in the Caribbean, turned out to vary considerably among themselves in general and to lack some of the proposed pan-creole features in particular. In addition, some languages that are not believed by anyone to be creoles have the entire proposed set of 'creole' features. The laundry-list approach has been revived recently (see McWhorter 1998), but it has not convinced skeptics to reconsider their rejection of the idea. Another proposal, which has not been discussed as much, is that creoles can only be identified from an historical perspective, i.e., as languages which cannot be shown to have descended as entire languages, lexicon as well as all grammatical subsystems, from a single parent language (see e.g., Thomason 1997b, Thomason and Kaufman 1988).

The above sketch of pidgin and creole structure and genesis necessarily omits mention of some lively areas of debate within the field. One more of these must be mentioned briefly: how do we draw the line between a pidgin and a creole? The traditional view has been that pidgins are languages without native speakers, while creoles have a population of native speakers. This distinction was once believed to correlate with levels of linguistic elaboration: the common-sense assumption was that a trade pidgin, with no native speakers and with functions restricted to typical second- (or third-, etc.) language uses would of course have limited linguistic resources, while a creole, serving as the main language of a speech community, would have all the elaboration in lexicon and structure that any other native language has. Unfortunately, this tidy correlation breaks down when one considers pidgins that have expanded their functions dramatically without acquiring native speakers. Tok Pisin, although it eventually did

acquire a native-speaker population, was such a language during part of its history: its functions expanded until they covered many or most aspects of daily life, and were limited only in the (presumable) lack of baby-talk and perhaps a few other aspects of home life. There is now no clear, simple, generally accepted way of distinguishing pidgins from creoles, though scholars continue to debate the issue. My own view (which is not shared by all specialists) is that any definition based on spheres of usage and their correlation with linguistic resources will inevitably have to allow for a very fuzzy boundary between pidgin status and creole status. How many functions are required for creole status? How much structure and lexicon are required for creole status? And if a population of first-language speakers is considered necessary after all, how many children constitute a population? It is hardly surprising, given the fact that pidgins can turn into creoles (by whatever set of criteria one adopts), that no sharp line can be drawn between the two categories; but the issues continues to be a matter for lively debate.

Bilingual mixed languages, the third type of contact language, differ sharply from pidgins and creoles, both linguistically and socially. What all three types have in common socially is their origin in some extreme form of contact—pidgins and creoles because they are needed for interethnic communication, bilingual mixed languages because they are needed (or at least wanted) as a symbol of ethnic identity. Pidgins and creoles always develop in the absence of full multilingualism, where there is no shared medium of communication; bilingual mixed languages always develop among bilinguals, who share not just one but two (and possibly more) languages. Bilingual mixed languages are not, therefore, needed for purposes of interethnic communication; on the contrary, they are in-group languages.

As the name suggests bilinguals create bilingual mixed languages. Although it's hard to be sure, given the paucity of well-understood cases, these languages seem to fall into two categories: most arise (relatively) abruptly as symbols of new ethnic or subethnic identities, but others arise gradually as symbols of ethnic identity among persistent ethnic groups—groups that had their own language originally but have come under so much cultural pressure from another speech community that their group identity is threatened. Michif, the language of mixed-blood French and (primarily) Cree speakers in south-central Canada, is one example of an abruptly created bilingual mixed language; Mednyj Aleut, the language of mixed-blood Russian and Aleut speakers on Mednyj (Copper) Island off the east coast of Russia, is another. In both cases, the mixed-blood population was viewed by its members and by the larger community as a separate group, with different economic and social and sometimes even

463

legal status from pureblood members of the two component groups. A well-documented bilingual mixed language that apparently arose gradually is Ma'a, a Tanzanian language of (by hypothesis) a Cushitic speech community that became partially integrated with two different Bantu-speaking communities. Ma'a is a case of unusually stubborn resistance, perhaps over several centuries, to total assimilation by two culturally dominant Bantu-speaking groups.

Structurally, the languages in the two groups differ significantly, though this assertion must be taken with a large grain of salt in view of the small number of examples. In the abrupt type there is a sharp split between the linguistic components taken from the two languages: Michif has French noun phrases (lexicon, phonology, and morphosyntax) and Cree verb phrases and general sentence structure (lexicon, phonology, morphosyntax); Mednyj Aleut has mainly Aleut lexicon and structure (albeit with numerous Russian borrowings) except in the finite verb morphology, which has been imported virtually intact from Russian, replacing the entire elaborate Aleut system of finite verb inflection (see *Intertwined Languages*). A third example, Media Lengua of Ecuador, has an entirely Spanish lexicon and an entirely Quechua structure (phonology and morphosyntax). In sharp contrast, in the gradually developing type of bilingual mixed language, e.g., Ma'a, all parts of the structure and lexicon of the threatened language are influenced by the dominant group's language. In its earliest documented form, Ma'a had a few non-Bantu structural features in different grammatical subsystems; present-day Ma'a has almost entirely Bantu structure, and its non-Bantu material is confined to a large but not numerically dominant proportion of the lexicon, including much or most of the basic vocabulary. Describing Ma'a as a gradually-developed mixed language is still a controversial stance (for a discussion of the controversy and arguments for gradual development, see Thomason 1997a), at least to some extent, but the scenario for absolutely abrupt creation is also controversial (see e.g., Mous 1994 for arguments in favor of abrupt creation).

It has been claimed that bilingual mixed languages consist of the lexicon of one language and the grammar of another (Bakker 1997, Bakker and Muysken 1995). But this scenario doesn't fit several of the few languages that have so far been systematically described in any depth—Media Lengua fits the picture, but Michif, Mednyj Aleut, and Ma'a do not—so that it does not seem at present to be a very promising theory. It is safe to predict that other theoretical controversies will arise as more bilingual mixed languages are discovered and analyzed.

Endangered Languages

L. A. Grenoble and L. J. Whaley

A language is classified as endangered if there is an imminent risk of it no longer being spoken. While the risk to the vitality of a language may arise from any number of factors, often acting in combination, two basic types of language endangerment situations exist. First, many languages are endangered because there has been a measurable decline in the percentage of children who learn to speak them over the course of two or more generations. The trajectory of the decline in the number of people learning these languages is such that at some point intergenerational transmission will cease. At that point, the language is considered moribund and has little to no chance for survival. The second type of endangered language is one that has a small number of speakers overall. Though many such languages are thriving under the social conditions that currently hold, their limited speaker base renders them susceptible to rapid language loss should conditions change.

Within these two broad categories of endangered languages there is a high degree of variation in how close to extinction particular languages are. For example, Orok, an indigenous language of Russia and Japan, has fewer than 100 fluent speakers, none of them children. In contrast, Nenets, another minority language of Russia, has 27,000 speakers, including a sizable number of children, and live in relatively isolated conditions, with limited contact with other languages. Still, there is an obvious trend towards children learning Russian rather than Nenets. While both these languages are endangered, it is all but certain that Orok will cease to exist as a living language within the next 50 years, whereas the prospects for the long-term survival of Nenets, though still not good, are better.

In order to capture the difference between the different types of endangered languages and the relative degrees of vitality among them, several different classifications have been proposed. Though differing somewhat in the details and terminology, all these classifications make at least a four-way distinction. First, 'threatened languages' are those languages for which long-term survival is a possibility, but which are vulnerable to rapid language loss. The vulnerability may stem from a number of factors, e.g., a small population of speakers or social transformations that decrease the necessity for using the language in daily activities. Second, 'declining languages' are those languages that are evincing a steady erosion to their speaker base, primarily due to the fact that fewer and fewer children learn the language in their homes. Third, 'moribund languages' are those languages that are no longer being learned by children as first languages. Short of extraordinary measures to revitalize such languages, they will cease to be spoken fluently by anyone within the span of a generation. Finally, 'extinct' languages are those languages that have no speakers left.

With regard to the fourth category, it is important to identify a crucial difference between the notion of an 'extinct language' and a 'dead language' such as Latin or Sanskrit. While the former describes a language whose loss is brought about by a disruption in intergenerational transmission, the latter is a language that represents a prior historical stage of a living language. For instance, though Latin is no longer spoken as it was in the fourth century, in a very real sense it is still being spoken, though in forms that are now called by different names such as French, Italian, and Spanish. Language change is a natural and constant process; spoken languages are continually evolving. In contrast, moribund and extinct languages generally arise at the point when they are no longer evolving because speakers have shifted to using a different language. Therefore, while extinct languages and dead languages share the property of having no fluent speakers in the contemporary world, the reasons for this are dramatically different (see *Language Maintenance, Shift, and Death*).

1. Statistics on Endangered Languages

Accurate statistics on the number of languages that are endangered, declining, or moribund do not exist. Part of the reason for this fact lies in the differing conceptions of what constitutes a language versus a dialect (see *Language*), thereby making it difficult to establish how many languages there are in the first place. Moreover, inadequate linguistic surveys have been undertaken for some regions of the world, which contributes to the problem of establishing how many languages are spoken. Even so, most experts place the number somewhere between 6000–7000. More significant than the indeterminacy in the overall number of languages, is the paucity of knowledge about how widely they are used and by whom. The single best source of information of this type is found in the *Ethnologue* (Grimes 2000), yet even this source contains only limited data on language vitality.

While precise calculations on the number of endangered languages are not available, good estimates have been made about the current situation. Perhaps the most widely cited figures are those

465

of Michael Krauss (in Hale et al. 1992). Krauss calculates that there are 600 languages in the world that can be considered 'safe,' i.e., not endangered, declining, or moribund. He defines this class as containing those languages with a speaker population of over 100,000 people or with official state support. Assuming there to be 6000 languages in the world, Krauss thus establishes that only 10 percent of languages are safe. He further estimates that of the 90 percent of languages that are not safe, well over half are moribund, though this number is primarily impressionistic.

Statistics such as these must be treated with some care since they are cast in summary fashion and do not take regionally specific variables into consideration. While the claim that 90 percent of the world's languages are endangered, declining, or moribund has been widely accepted, there is some disagreement over what number of these languages is likely to become extinct in the present century. This apparent discrepancy arises because facts about numbers of speakers and language use are ultimately meaningless unless they are interpreted within the context of the regions where the languages are spoken. For example, in the People's Republic of China, a language spoken by most members of an ethnic group numbering in the tens of thousands must be considered in a precarious state since the number of monolingual Chinese speakers living in the same region is proportionately much higher and because China has an educational policy that aggressively promotes Mandarin Chinese over minority languages. However, a language in a speech community of the same size in Papua New Guinea, where there are hundreds of small language groups, would represent one of the larger languages in the country. In this sort of context, one might predict the continued use of the language into the indefinite future.

2. Causes of Language Endangerment

Regardless of whether one puts the number of languages that are likely to disappear from the earth in the next 100 years at 50 percent or 90 percent of the current total, the statistic is alarming. The conditions necessary to bring about this extreme rate of language extinction have their roots in the period of colonization and in the rise of industrialization and the modern nation-state (see Nettle and Romaine 2000 for a good overview). Colonization meant, in many instances, the decimation of indigenous populations around the world due to the spread of disease and conquest. It further entailed the displacement of many indigenous groups from traditional lands. With the onset of industrialization and the formation of nations came governments that implemented educational systems and language policies designed to unify their populations. Either explicitly or implicitly, such efforts included the drive to assimilate indigenous groups. Many of the languages of the world are known to have become moribund as a direct result of these efforts.

Recognizing the effect of such historical trends provides some understanding as to why declining and moribund languages are not evenly distributed throughout the world. In regions of the world where a colonizing group successfully conquered indigenous people and descendants of the colonizing groups now represent the majority culture of a country, an extremely high percentage of languages are moribund or near moribund. Such regions include most parts of the Americas, Russia, Australia, and China, among others. In regions where colonization did not occur, or did not occur in the same way, such as many parts of South East Asia and Africa, the percentage of moribund language is much lower.

The sociopolitical composition of the modern world, and perhaps more importantly its economic systems, do not provide a favorable environment for endangered languages. In many countries, educational policy promotes monolingualism in a nationally or regionally dominant language. This is reinforced by telecommunications technology such as radio, television, and the Internet, that relies on widely spoken languages. The exploitation of natural resources increasingly leads to the displacement of minority populations that speak endangered languages. The ensuing disruption to their cultural patterns often leads to language decline. Civil wars have a similar effect. In many communities where endangered languages are spoken, there are changing attitudes towards material prosperity and subsistence that lead to increasing numbers of young people leaving the community. The majority of the world's population speaks an ever decreasing number of languages. Mandarin Chinese, Spanish, English, Bengali, Arabic, and Hindi are among the most rapidly growing languages, acquiring speakers at the expense of a large array of languages with a smaller speaker base.

The rate of language decline and extinction is far greater now than it has ever been in history. The linguistic diversity of the world will almost certainly be cut in half in the next 100 years, and the modern situation does not paint an optimistic picture for the vitality of countless other languages. For this reason, an increasing amount of interest and research has been generated on the topic of endangered languages in the last several decades. There has been a groundswell of interest by communities that speak endangered and declining languages to revitalize or maintain this aspect of their heritage. As a result, language programs have sprung up around the world. It remains to be seen

whether such efforts can be successful for the long term.

English as a Foreign Language

G. Abbott

The term 'English as a Foreign Language' (EFL) implies the use of English in a community where it is not the usual means of communication, 'English as a Second Language' (ESL) being used where the language has important social functions in the community—as a medium of education or jurisdiction, for example. The terms EAP and ESP refer to contexts in which the adult learner has an academic or other specific purpose. In educational contexts the label EAL (English as an Additional Language) is also used so as to emphasis the value of the learner's first language. The American term TESOL (Teaching English to Speakers of Other Languages) is ousting its British equivalent, ELT (English Language Teaching). All these terms contrast with 'English as Mother Tongue' (EMT) or 'English as First Language' (EL1). Though this article will concentrate on EFL, the other aspects cannot be entirely excluded. It will first review the major reasons for the phenomenal increase in the use of English worldwide and illustrate current uses of EFL as an international language. Some developments in the Teaching of English as a Foreign Language profession (henceforth TEFL) and its associated industries are then described. The final sections deal with three issues likely to be of continuing concern: issues of education, culture, and intercomprehensibility.

1. The Diffusion of English

The first extant textbook for foreign learners of English was written for French Huguenot immigrants by Jacques Bellot, himself a Huguenot. It was published in London in 1580 at a time when English, according to Bellot's contemporary John Florio, was 'worth nothing past Dover' and even within Britain was not understood everywhere. Since then the use of English has spread throughout the world until at conservative estimates, in the late twentieth century, there are 300 million mother tongue speakers, a similar number of ESL users and a further 100 million fluent EFL speakers. The development of TEFL since Florio's time is chronicled in Howatt (1984). The sheer quantity and distribution of English speakers (see Crystal 1987: 358–9) are directly attributable to the rise of two successive world powers, Britain and the USA.

The administration of the British Empire's largely multilingual territories necessitated the use of a common language, and in most cases English was the only feasible choice. Although the use of the vernacular (see *Vernacular*) was encouraged in the first years of primary schooling, the selective secondary schools usually drew multilingual groups from much wider catchment areas. English was therefore inevitably chosen as the medium of instruction.

By the time the British Empire had been dismantled the foundations of the 'English Empire' had been laid. The British Council and the BBC continued the diffusion of English and the USA, by the mid-twentieth century a formidable world power, had her own reasons for encouraging the world to learn English—reasons which were largely ideological. A decision to teach exotic languages to armed forces personnel during World War II had given an impetus to foreign language teaching approaches which were then applied to English, Fries (1945) being especially influential. The ensuring Cold War prompted the US State Department's Foreign Service

Institute to employ applied linguists to produce courses in languages of strategic importance, and the success of the first Sputniks further stimulated this activity. The Center for Applied Linguistics was established and the export of English was supported by the Ford Foundation, the Fulbright Program, the Peace Corps, and the Voice of America radio transmissions.

The growing international status of English was not simply the result of a quest for Empire and a crusade against totalitarianism. Immigration into America, the UK, Australia, and Canada also acted as a spur to domestic ESL provision, which in turn influenced TEFL methodology. However, the emergence of English as an international language probably owes more to a phenomenon observed long before in Bengal.

2. English as an International Language

West (1926: 107) had noted that in the publication of books on technical subjects not only was the combined production of Britain and the USA almost 50 times larger than the local output, but also the continuing expansion of technical knowledge published in English would outpace any attempt to translate it into Bengali. For countries not technologically developed, English was already an invaluable means of access to new scientific, medical, and technical information. By 1980 more than two-thirds of the world's scientists were writing in English and of all the world's electronically stored information, 80 percent was in English (Crystal 1987: 358). Since the First World/Third World development gap appears to be widening, this function of English will probably continue to grow.

Improvements in the technology of travel brought commerce and tourism to a point where a single common language was needed, and the world chose English. Advances in electronics produced global networks for sound and vision providing instant access to the world's news: in repressed societies British, American, and Australian news in English was relied upon for its accuracy. Politically, English became the international language of protest and economic development.

2.1 Restricted Englishes

Restricted forms of English were established for international operational purposes. The speed, volume, and geographical range of modern transport systems had necessitated internationally agreed ways of ensuring that traffic flows were as efficient and hazard-free as possible. In international civil aviation a common language was needed for air crews and ground control staff to exchange messages, and English was the obvious choice. However, natural languages contain potential ambiguities which in certain circumstances could lead to fatal misunder-

standings. The instruction 'Go ahead,' intended to mean 'Proceed with your message,' had on one occasion been interpreted by a pilot as 'Continue your present course,' and his aircraft had crashed. It is therefore a carefully restricted English called 'Airspeak' which, by international agreement through the United Nations, is used by today's world airlines (see Robertson 1987).

Controlling heavy traffic in sea lanes and responding rapidly to mariners' calls for help present fewer problems now that there is an internationally agreed language of ship-to-ship and ship-to-shore radio communication, a disambiguated English called 'Seaspeak' (see Weeks et al. 1988). With the linking of the UK to Europe by means of the Channel Tunnel, another restricted English was needed for the police forces at each end to use when communicating by telephone. This operational English is called 'Policespeak.'

3. TEFL as a Profession and as an Industry

The increasing international dependence upon English as a working language enhanced not only the size but also the status of the TEFL profession in those countries where it is the mother tongue. Here the world's growing need for well-trained teachers was catered for by the establishment of specialist TEFL postgraduate courses, up to doctorate level, both for nationals of the various countries seeking such assistance and for mother-tongue speakers of English wishing to teach EFL/ESL overseas. This in turn necessitated the recruitment of suitably experienced and qualified academic staff.

The incessant demand for tuition in EFL led to a massive growth of provision in the private sector, a development encouraged by US/UK economic policies from the 1980s onwards. In the UK, quality-control systems were set up to award recognition only to establishments found to be of satisfactory standard; participation in such schemes is voluntary, however. Some recognized private institutions undertake teacher education and other high-level training activities both at home and abroad, as well as direct language teaching.

3.1 Publishing

On both sides of the Atlantic, publishers hastened to add TEFL to their repertoires or to expand their existing lists. They now produce a plethora of textbooks, books for teachers, workbooks, visual aids, sound and video cassettes, and computer software. The publication of such materials is in itself a multimillion dollar international industry in which some textbook-writers have become millionaires.

3.2 Testing

The higher education systems of these countries also began to cater for a growing number of applicants from overseas, especially from the Third World, who had to pursue their various fields of study through the medium of English. There was consequently a need not only to provide training in the use of English for academic purposes but also to develop reliable methods of assessment which would determine for each applicant the amount and nature of the tuition needed. The best known of these standardized tests are the TOEFL (Test of English as a Foreign Language) used in America and the IELTS (International English Language Testing Service) developed by the British Council. Another highly profitable industry arose from a demand for certificates of proficiency that would help the holders to obtain employment or promotion, or even to become EFL teachers themselves. In the UK, so many examining boards established their own tests at various levels of proficiency that, in order to help learner, teacher, and employer alike, the English Speaking Union commissioned a framework (Carroll and West 1989) to facilitate comparison of the tests in terms of level, content, and coverage.

3.3 Anglocentrism

A perhaps inevitable consequence of the activity mentioned above was 'anglocentrism,' a tendency to assume that what was suitable for the privileged circumstances of a school in Los Angeles or London was suitable for use in Venezuela or Vietnam. The modern communicative movement in language teaching (see *Communicative Competence*) was developed in circumstances in which well-trained and well-paid teachers taught highly motivated students in smallish groups able to move about in spacious well-equipped classrooms, and usually had access to reprographic facilities and secure storage space. It was sometimes forgotten that, in a worldwide perspective, these were unusually privileged circumstances and that communicative methods had to be modified, sometimes severely, in less favored conditions. Though there has been a resurgence of interest in the issue of large classes, there has been no breakthrough in the problem of how to deal satisfactorily with classes of, say, 200 students—a quite normal feature of TEFL in Pakistan, Burma, and elsewhere.

A welcome development which may counteract anglocentrism was the establishment of professional organizations far from the 'anglocenter.' Teachers' associations such as the USA-based TESOL, TESL Canada, and the UK-based IATEFL were at one time balanced only by RELC (SEAMEO Regional Language Centre) in Singapore, and CIEFL (Central Institute of English and Foreign Languages) in Hyderabad, and even these were not run by teachers. The 1970s and 1980s witnessed the setting up of EFL teachers' associations in various parts of the world. Examples include MELTA (Malaysian English Language Teachers' Association) in Kuala Lumpur and SPELT (Society of Pakistan English Language Teachers) in Karachi. Enthusiasm and commitment are often such that the groups produce their own journals and organize national and even international conferences.

4. EFL as Education

Although state school TEFL in many parts of the world benefited indirectly from the lively professional activity outlined above, research and development tended to focus on postschool rather than in-school needs—in contrast to the ESL context, in which a great deal of useful school work was done (see *Education and Language: Overview*). In 1971 the Council of Europe asked a term of applied linguists to devise specifications for the teaching of languages in the EC member states; the objective was to provide, for those whose employment involved crossing European linguistic borders, syllabus components that were comparable whatever the language being learnt. The outcome was an inventory based upon the predictable workaday language needs of such citizens. This inventory, complied with working adults in mind, was merely copied when a subsequent specification for schools was produced.

While TEFL has seen great advances in the identification and use of the particular language forms and functions needed in a given higher education of course or occupation, no comparable energy has been devoted to the development of a rationale for EFL as a school subject. Where adults have current language needs that are analyzable and imminent needs that are predictable, the EFL learner in school usually has neither; the younger the learner the more TEFL becomes TENOR (the child having 'No Obvious Reason' for studying English) and the more important are one's educational aims in teaching the language. Stern (1984: 10) rightly pointed to 'a lack of contact among applied linguists with curriculum theory in general educational studies.'

The uneducative content of many an EFL textbook was often cited as a case in point. Too often the books contained inconsequential passages, frequently about pseudotypical characters (e.g., 'The Smith Family'), followed by mindless exercises comprising lists of sentences, unrelated except for the grammar point they illustrated. Suggestions for a more educative content were put forward and some have begun to materialize in school teaching materials. They include: teaching another subject through English, as in ESL contexts; imparting facts that are considered important as general knowledge; using

469

the nature of language and communication as a subject of study; and using the pupils' own preoccupations as lesson material. Last, but by no means least in a world of increasing multiculturalism and widening interdependence, such educational objectives as 'awareness of world problems' and 'tolerance of cultural difference' may well prove at least as important as merely linguistic aims. If so, EFL programs in the world's schools will be required to play their part; but for that to happen TEFL needs to be incorporated into a sound framework of educational theory in which it is the needs of the child as a developing person, rather than the demands of the state and the employer, that are paramount.

5. EFL and Culture

To the applied linguist as to the anthropologist, a 'culture' is the sum of learnt systems shared by and defining a social group; it is not limited to the fine arts that the West associates with Culture, an abstraction with a capital C, but embraces all the group's methods of ordering and expressing its way of life, including its use of language, facial expression, and gesture. One normal consequence of teaching any natural language, therefore, is the imparting of elements of the culture that the language reflects. Kramsch (1998) provides a recent overview of the relationship between language and culture which is of relevance to TEFL practitioners. Given the scale of EFL teaching and use, it is not surprising that in many areas of the world uneasiness has been expressed concerning the transmission of Western culture.

Cultural transmission may take place in at least three ways in the language classroom: as lesson content it may be intentional, incidental, or inherent.

5.1 Intentional Transmission

If the passages, dialogues, and illustrations in an EFL program have an EMT setting, e.g., 'An American Family' or 'The British Queue,' it may be assumed that the material is an intentional cultural component of the learning program. (If on the other hand the textbook material were to depict local children in local settings conversing in faultless English, the lack of authenticity would elicit ridicule. Finding appropriate settings can be a problem.) Intentional content may either be left to speak for itself or discussed, through the MT if need be, in contrast to a corresponding component of the learner's culture (e.g., 'Boarding a Bus in London and Lahore'). Texts representing 'high culture' may also be used. EFL programs in the former USSR, for instance, included study of certain poems by Robert Burns and selected passages for Dickens, Jack London, and Hemingway, at which point English Literature was deemed to stop—a reminder that 'culture' includes 'ideology.'

5.2 Incidental Transmission

The expatriate teacher, as a native speaker of English, has a worldview laden with cultural values different from those of his students. These include preconceptions about morality, education, and classroom behavior which color everything that happens in a class, however unaware the teacher may be that this is happening. Educational authorities may prefer local staff to such guest teachers for this reason.

Also included here, though some might prefer to view it as intentional cultural transmission, is the linguistic and nonlinguistic behavior demanded of even local teachers by syllabuses aiming at communicative competence (see *Discourse in Cross-linguistic and Cross-cultural Contexts*). For example, to ask a young woman student or teacher to express strong emotion and to accompany her utterances with body language typical of an EMT community will be seen in Southeast Asian societies as a very embarrassing cultural imposition. On the other hand, learning what to expect in the foreign culture, and learning what to avoid doing, are seen as helpful. People of certain Asian cultures about to depart for the UK will be happy to learn not only how to form grammatically correct questions in English but also that certain questions (*How old are you? How much do you earn?*) are not used on first acquaintance. Comparisons of the MT rules for communicative competence and the English equivalents are improving EFL programs in this respect.

5.3 Inherent Transmission

It has long been accepted that one cannot learn a language without imbibing some of the cultural information it embodies. It was for this reason that regimes diametrically opposed to EMT cultural values used language teaching texts that were merely party ideology translated into English, simple words such as *correct* being made to take on new meanings, and *democracy* meaning opposite things in the two camps. In Eastern Europe, where it was often necessary in public to use a Stalinist dialect which contradicted everyday realities—a situation that has been labeled 'political diglossia'—effects similar to schizophrenia were reported.

Applied linguists agree to differ on how far one's mother tongue influences the structure of one's thinking processes (see *Sapir–Whorf Hypothesis*), but few would deny any causal connection. It seems unlikely that learning to use EFL would greatly influence the mentality of the learner unless English came to replace the mother tongue.

5.4 Cultural Imperialism

Any of these aspects of cultural content in EFL lessons may be seen as neoimperialism, depending on the particular circumstances—the real or perceived

intentions of the teacher, the wishes of the students, the views of their parents, the ideological stance of the education authorities, and so on. There is certainly a danger that some communicative activities might be seen as assimilationist ('You should behave more like us'); common sense and cultural sensitivity are needed on the part of both materials writer and teacher. It has further been suggested by Abbott (1992) that Third World perceptions of the benefits accompanying a command of English may, by undermining indigenous cultures, inhibit the development process. Certainly, an uneasy feeling persists in many quarters that the promotion of TEFL is a form of cultural imperialism (see *Linguistic Imperialism*).

6. Intercomprehensibility

The need to avoid cross-cultural incomprehension or misunderstanding gave rise to the restricted Englishes mentioned above (Sect. 2.1) and to a proposed general-purpose code called 'Nuclear English' (Quirk 1981) which would be culture-free and therefore not perceived as neo-imperialist; but Quirk's proposals were not developed into a usable code. The need worldwide is to ensure comprehensibility among natural Englishes.

6.1. Natural Englishes

Quite apart from the varieties that constitute 'English' in the minds of its native speakers and which Kachru (1985) labels 'the inner circle,' there are also what he calls 'the outer circle' and 'the expanding circle' of Englishes. The outer circle comprises all those forms of English such as Indian English or Nigerian English which, though not indigenous and not the users' mother tongues, have become 'institutionalized' (i.e., part of the nation's working life) and 'nativized' (i.e., modified by the local cultures and thus more comfortable and efficient as vehicles for international messages). Kachru's 'expanding circle' consists of truly foreign Englishes such as Japanese English and Iranian English. Given that nonnative speakers of English already outnumber its native speakers and that the quantity of international communication in English within and between the outer and expanding circles is increasing, there is a continuing need to ensure intercomprehensibility (see *New Englishes*).

6.2 The Learning-model Question

In the expanding circle, the need to have an inner circle standard form of English as a learning-model has not seriously been questioned, Europe traditionally opting for British English and 'received pronunciation' (see *Accent*). In outer circle countries, however, it has been proposed that the standard form of each nativized English should serve as the national model. Nigerians, for example, who rightly regard English as their own (it is their national language), might well find this policy attractive for reasons of national identity and pride. It has been objected that since all nonnative Englishes whether nativized or foreign are subject to mother-tongue interference (see *Language Transfer and Substrates*) they would, in the absence of a shared model, be pulled in different directions, thereby threatening intercomprehensibility.

Where international intelligibility is the aim, there may have to be a high degree of commonality among the models used, and at present only the mother-tongue standard Englishes of the inner circle can satisfy this requirement. The image of non-mother-tongue Englishes held in orbit by the gravitational force of mother-tongue standard Englishes may at first seem neoimperialist; but this maintenance of an optimum distance from the center may be justifiable not primarily because proximity to the center is important but because the greater the radius, the greater the distance between the nonnative Englishes. Increasingly, these Englishes are likely to differ considerably in their vocabularies and vary somewhat in their grammars; but if intercomprehensibility is to be assured, each variety may need to maintain a similar number of systematic phonemic contrasts. Another advantage of such a policy would be the maintenance of a reasonably close relationship between the spoken Englishes and the orthography of English, which allows very little variation in spelling. However, such a vast field may not lend itself to applied linguistic activity at all, and Crystal (1997) believes that a common global dialect, 'World Standard Spoken English' is likely to arise naturally. McArthur (2001) gives an up-to-date overview of the global condition of English.

Though education, culture, and intercomprehensibility have been addressed separately above, they are of course not discrete phenomena in the practice of TEFL. Since attitudinal factors are a significant influence in language learning, the successful education of English-users, whether native or non-native speakers of the language, will include the promotion of positive intercultural attitudes which in turn will facilitate mutual understanding across linguistic boundaries

Ethnolinguistic Vitality

H. Giles

Communication between groups depends not only on the nature of the immediate context in which it occurs, but also on the sociostructural background in which the social categories are historically embedded. In order to explore the latter in (originally) the interethnic sphere as well as relate it to sociolinguistic usage, Giles et al. (1977) introduced the concept of 'ethnolinguistic vitality.' This articulated the main sociostructural features defining a group's relative position to others in society vis-à-vis three principal components. Derived, in large part, from factors found predictive of language maintenance, these were *status* (e.g., economic, historical), *demography* (e.g., numbers, birthrates), and *institutional support* (e.g., representation of the group and its language in the media and education).

Subsequently, scholars have fruitfully analyzed groups' 'objective vitalities,' such as the number of TV programs and newspapers in an in-group's language, and contrasted these with other out-groups' capital. The real challenge of the vitality framework was, however, to provide a *subjective* assessment of how members of ethnic collectivities judged the societal conditions impinging on their own and relevant out-groups. To this end, Bourhis et al. (1981) devised a 22-item instrument (the SVQ) to tap individuals' vitality *perceptions*—and this scale has subsequently been accorded high internal reliability.

SVQ research has underscored the notion that the supposedly same societal conditions can be viewed in different ways by interested parties involved. For instance, Anglo-Australian students in Melbourne polarized vitality differences between their own group and Greek-Australians who, in turn, attenuated them (see Harwood et al. 1994 for a typology of different intergroup vitality profiles). In Hong Kong, a more differentiated intergroup vitality profile emerged where Western and Cantonese students each favored their own in-group on items relating to language status, yet considered their respective out-groups to have significantly more control and power on other scales. Furthermore, and comparing Hong Kong bilinguals' ratings before, with those immediately after, the signing of the Sino-British Treaty (1983), Chinese vitality was perceived to have increased whereas Western vitality diminished. Arguably, little (if any) objective changes accrued during this 18-month period.

Vitality is not then static given but, rather, a malleable social construction depending on social group memberships and fluctuating sociopolitical circumstances. Also, vitality perceptions are a function of which target groups are in the evaluative frame, whether the context is the very local neighborhood community or a larger provincial entity, and so forth. Allard and Landry (e.g., 1986) have extended our conceptions of *general* in out-group vitalities to encompass other related belief systems (e.g., how groups feel the relative positions should be as well as what they could be in the future—their normative and goal vitalities, respectively), and related these to individuals' linguistic networks. The empirical pursuit of which belief system is more predictive of language behaviors than others has engaged

comparative research yet, doubtless, future work will indicate each is potent in different sociolinguistic terrains.

Sociopsychological theorizing about language (e.g., ethnolinguistic identity theory) has accorded vitality an important mediating role in the sense that cognitive representations about it influence sociolinguistic behaviors. It has been argued that the more vitality in-group members believe they possess the more psychological resources they have available to bolster, as well as invest in, a strong sense of ethnic identification. Given that unique linguistic (and other communicative) criteria can be core elements of a valued in-group identity, such feelings could engender linguistic differentiation from out-group members (e.g., dialect divergence) in social interaction. Indeed, high-perceived vitality is proposed to be necessary to preserve a whole range of language maintenance and survival strategies.

Hence, the more vitality another group is seen to possess, the more motivated people are to acquire their modes of communication (see, for example, Cenoz and Valencia 1993). One soldier in Barkhuizen and de Klerk's (2000) study of a South African army camp commented: 'Yes, but I'm a Sotho, because of the majority of the peoples here they are Xhosa speakers, you see. So that is why most of the time I try to learn Xhosa. The Sothos and Venda they try to learn Xhosa' (p. 108). Nonetheless, and as the intergroup model of second language learning suggests, the desire to assimilate towards a highly vital language can be stymied when speaking it threatens learners' sense of group belonging (see Harwood et al. 1994 for related propositions and their schematic 'vitality theory'). Relatedly, perceiving and reading about the ever-increasing vitality of minority out-groups in terms of increased numbers (with political influence) can foster language ideologies among Anglo-Americans, such as the English-only Movement (Barker et al. 2001). Such sentiments can become acute when an out-group's language becomes more and more visible in the 'linguistic landscape' via public and commercial signs.

While such empirical relationships have not always emerged, and *low* perceived in-group vitality can even *mobilize* intergroup linguistic differentiation among very ethnically-identified individuals, work continues to blossom cross-disciplinarily and cross-culturally concerning the descriptive and explanatory roles of vitality (e.g., Atkinson 2000, Ellinger 2000). Indeed, it has been found (among Vietnamese-Australians) that perceived high in-group vitality is an important predictor of non-language outcomes, such as satisfaction with home life, educational achievements, and occupational aspirations.

Although the vitality construct has at times attracted controversy and been subjected to healthy scrutiny (e.g., McCann 2000), its utility extends beyond interethnic encounters into theoretical discussions of between-gender, heterosexual–homosexual, and intergenerational communication. Clearly, the psychological weight afforded the different vitality constituents (and doubtless others to be located) will depend on the particular intergroup context studied—and this is a compelling prospect for future research. Furthermore, what Harwood et al. (1994) refer to as the volume, tone, and focus of 'vitality talk' in their discursive analyses of small group discussions and the newspaper media open up exciting new directions (ethnographic and other) for understanding the critical roles of this construct in diverse sociolinguistic domains.

Foreigner Talk
M. Clyne

Foreigner talk (also known as xenolect) is a variety of a language employed to a person identified as a foreigner, usually in order to ease communication. Like baby talk (motherese), it generally involves a reduction or simplification. The term was devised by Ferguson (1971). Descriptions of foreigner talk in a number of languages are available (including Dutch, English, Finnish, French, German, Russian, and Turkish). Sometimes, foreigner talk may reflect a condescending attitude towards foreigners or frustration with their language proficiency.

1. Linguistic Indices

Foreigner talk is subject to considerable variation between speakers and to variation within one speaker's speech according to the interlocutor and the nature and function of the discourse segment. Explanations and narratives are most susceptible to simplification. Roche (1989) has postulated four levels of German utterances in communication with foreigners: (a) native-type, (b) gravitation towards the standard language, (c) slight grammatical reductions and lexical simplifications, and (d) gross grammatical reductions and lexical simplifications. It is the last level that has been described most frequently.

The major linguistic indices are:

> elliptic sentences, e.g., *soon ready*;
> deletion of grammatical endings, e.g., *she never come*;
> the non-realization of function words such as the copula (*be*), articles, auxiliaries, prepositions and/or pronouns, e.g., *he busy; no start; he nearly finish; how long time take you?*;
> and the simplification of the lexicon, e.g., German *nix gut* ('no (nothing) good' for *schlecht* 'bad'), *mehr schwer* ('more heavy' for *schwerer* 'heavier').
> In some languages, the infinitive form is overgeneralized.

With the absence of inflexions, which provide vital information for comprehension, some word-classes are ambiguous. For instance, the second word in 'No finish' could be interpreted as either a noun or a verb. In German and Dutch, the Subject–Object–Verb (SOV) word order is frequently overgeneralized, e.g., *Heute nix arbeiten?* (Standard German *Heute arbeiten Sie nicht?*).

Apart from being syntactically marked, foreigner talk can be phonologically marked, where the native speaker will attempt to produce more 'foreign' sounds. Some speakers of Australian English will replace English diphthongs by monophthongs, for example, [e:] instead of [ɛɪ] and [o:] instead of [ou]. They will also articulate a trilled [r]. Foreigner talk is also louder and slower than normal native speech, with longer pauses between the crucial items.

The level chosen at the beginning of an interaction is determined by assumptions of foreignness which may sometimes be influenced by extralinguistic factors (racial features, dress). The level is adjusted according to the interlocutor's command and the type of discourse (Roche 1989).

2. Contexts of Foreigner Talk

Foreigner talk is, and has been, used in colonial plantation situations. It is very prevalent today on the factory floor and in service encounters in countries that attract many immigrants, migrant laborers, and tourists. It is also employed in family situations by some children of immigrants to their (grand)parents. Here it usually replaces an ethnic language which the children have not maintained. In such cases it may form the beginning of an ethnolect such as Greek Australian English or Jewish Australian English.

3. Users

Foreigner talk has been described between indigenous children and foreign adults, between indigenous adults and foreign adults, between children of immigrants and their parents and other older members of their ethnic group, and between foreign adults and indigenous adults of a different race (e.g., Tok Masta spoken by expatriate Australians in New Guinea, Mühlhäusler 1981).

4. Relation Between Pidgin and Foreigner Talk

Foreigner talk tends to be used in convergence toward the speech of those with limited competence in the target language and using a pidginized learner variety of it. The question of whether such a variety is promoted and/or reinforced by foreigner talk is controversial (see, e.g., Meisel 1975 and *IJSL* 1981). Such a causal relationship seems to have existed in the early stages of Tok Pisin (Mühlhäusler 1981). In industrial settings, the linguistic markers of foreigner talk and early phases of learner varieties are much the same but represented in different proportions (Clyne 1977). Also, non-native speakers of a language with a native-like competence in it may be reverting to an early stage in their second language development when they use foreigner talk.

5. Methods of Studying Foreigner Talk

Foreigner talk has been investigated mainly through the taping of spontaneous conversations, occasionally with the same native speaker interacting with several foreigners or the same foreigner interacting with different native speakers. Sometimes foreigner talk versions of 'native' sentences are elicited from native speakers. This is supplemented by examples from literature.

6. Use of Foreigner Talk in Literature

A stylized version of foreigner talk, whose function is to characterize foreignness, is to be found in literature, including *Robinson Crusoe*, the German adventure novels of Karl May, *Watership Down*, and the French comic book series *Les aventures de Tintin*. Literary foreigner talk shares some linguistic indices with actual foreigner talk but they diverge in some ways. For instance, the use of the infinitive of auxiliaries and the ungrammatical inflections of verbs and adjectives prevalent in Karl May do not occur in actual German foreigner talk.

7. Future Directions

More empirical studies are needed in as many languages as possible so that universals of foreigner talk can be established. The use of videotape in research would improve understanding of how nonverbal phenomena such as gestures can supplement foreigner talk.

Interlanguage
E. Tarone

The notion of 'interlanguage' has been central to the development of the field of research on second-language acquisition (SLA), and continues to exert a strong influence on both the development of SLA theory and the nature of the central issues in that field.

The term interlanguage (IL) was introduced by the American linguist Selinker to refer to the linguistic system evidenced when an adult second-language learner attempts to express meanings in the language being learned. The interlanguage is viewed as a separate linguistic system, clearly different from both the learner's 'native language' (NL) and the 'target language' (TL) being learned, but linked to both NL and TL by interlingual identifications in the perception of the learner. A central characteristic of any interlanguage is that it fossilizes—that is, it ceases to develop at some point short of full identity with the target language. Thus, the adult second-language learner never achieves a level of facility in the use of the target comparable to that achievable by any child acquiring the target as a native language. There is thus a crucial and central psycholinguistic difference between child NL acquisition and adult second-language (L2) acquisition: children always succeed in completely acquiring their native language, but adults only very rarely succeed in completely acquiring a second-language. The central object of interlanguage research is to explain this difference—essentially, to describe and explain the development of interlanguages, and also to explain the ultimate failure of interlanguages to reach a state of identity with the target language. Thus, some central research questions are: What are the psycholinguistic processes which shape and constrain the development of inter-languages? How are these different from those processes which shape and constrain the development of native languages? How might these differences account for the phenomenon of fossilization?

1. The Interlanguage Hypothesis

1.1 Origins of the Concept of Interlanguage

The notion that the language of second-language learners is in some sense autonomous and crucially distinct from both NL and TL was developed independently at about the same time in the work of several different researchers (see Selinker 1992 for a detailed account of the historical development of this notion). Slightly different conceptualizations of learner language were referred to as 'approximative system' by Nemser and as 'transitional competence' by Corder. However, the notion of interlanguage seemed to be the one which caught on, and which is used in the literature on second-language acquisition in the 1990s.

Prior to the development of the idea of interlanguage, contrastive analysts had asserted that the second-language learner's language was shaped solely by transfer from the native language. Because this was assumed to be so, a good contrastive analysis of the NL and the TL could accurately predict all the difficulties which that learner would encounter in trying to learn the TL. These claims were made on logical grounds and almost always supported only by reference to anecdotal evidence. It is important to note that these claims were not supported by reference to data obtained from the systematic study of learner language itself, but usually only to utterances which analysts happened to have noticed and remembered. Unfortunately, it is all too likely that analysts tend to notice data their theories predict, and not to notice data which do not fit their theories. Learner utterances which were clear evidence of transfer were noticed and quoted, but learner utterances which did not provide evidence of transfer apparently went unnoticed or were classified as 'residue.' Thus, in the late 1950s and the 1960s, there were virtually no systematic attempts to observe learner language and to document scientifically the way in which learner language developed, or to independently and objectively verify the strong claims of the contrastive analysis hypothesis that language transfer was the sole process shaping learner language.

Lado (1957: 72), in an influential statement, explicitly characterized the predictions of contrastive analysts as statements which should be viewed as hypothetical until they could be validated by reference to 'the actual speech of students.'

Error analysis was an enterprise born of the attempt to validate the predictions of contrastive analysis by systematically gathering and analyzing the speech and writing of second-language learners. For perhaps the first time in history, the focus moved from teaching materials and hypotheses about second-language learning problems, to the systematic observation of learner language. The focus was what

scientific study could reveal about the real problems of second-language learners. Preliminary evidence from early studies began to come in, the results of which showed an increasingly large 'residue' of errors which did not in fact seem to be caused by transfer as contrastive analysts had predicted. These errors became an increasingly major source of difficulty for the contrastive analysis hypothesis, a hypothesis which had posed the interesting question of what shapes learner language, but which, increasingly clearly, could not answer that question satisfactorily.

Corder (1967, 1981) was the first and most persuasive scholar to develop an alternative framework: the idea that second-language learners do not begin with their native language, but rather with a universal 'built-in syllabus' which guides them in the systematic development of their own linguistic system, or 'transitional competence.' Thus, the second-language learner's transitional competence is different from either the NL or the TL or even some combination of the two, since it begins with an essential, simple, probably universal grammar. Corder also pointed out that the native language often serves as a positive resource for second-language acquisition, facilitating the learning of TL features which resemble features of the NL. Corder argued that second-language learners' errors were evidence of the idiosyncratic linguistic system which they were building, and so were valuable data for research into the nature of the 'built-in syllabus.' Corder called for research involving the analysis of learner errors gathered longitudinally, proposed a framework for eliciting and analyzing those errors, and posed the goal as one of characterizing the built-in syllabus and the transitional competence of second-language learners. His students and colleagues set about pursuing that enterprise.

The term 'interlanguage' was most persuasively introduced and developed into a set of testable hypotheses by Selinker (1972), after long conversations with Corder and other scholars in the field. The interlanguage hypothesis was intended to, and did, stimulate systematic research into the development of the language produced by adult second-language learners, with a view to objectively identifying psycholinguistic processes (transfer included) which shaped learner language, explaining how learners set up interlingual identifications across linguistic systems, and accounting for the troubling tendency of adult learners to stop learning, or to fossilize.

1.2 Defining Interlanguage

The term interlanguage was defined by Selinker (1972) as the separate linguistic system evidenced when adult second-language learners attempt to express meaning in a language they are in the process

476

of learning. This linguistic system encompasses not just phonology, morphology, and syntax, but also the lexical, pragmatic, and discourse levels of the interlanguage. The interlanguage system is clearly not simply the native language morphological and syntactic system relexified with target language vocabulary; that is, it is not the morphological and syntactic system which would have been evidenced had the learner tried to express those meanings in his/her native language. Just as clearly, it is not the target language system which would have been evidenced had native speakers of the target language tried to express those same meanings. Rather, the interlanguage differs systematically from both the native language and the target language.

Interlanguage is usually thought of as characteristic only of adult second-language learners (but see Sect. 2.1)—that is, learners who have passed puberty and thus cannot be expected to be able to employ the language acquisition device (LAD)—that innate language learning structure which was instrumental in their acquisition of their native language. Children acquiring second languages are thought to have the ability to reengage the LAD and thus to avoid the error pattern and ultimate fossilization which characterize the interlanguages of adult second-language learners.

Central to the notion of interlanguage is the phenomenon of fossilization—that process in which the learner's interlanguage stops developing, apparently permanently. Second-language learners who begin their study of the second-language after puberty do not succeed in developing a linguistic system which approaches that developed by children acquiring that language natively. This observation led Selinker to hypothesize that adults use a latent psychological structure (instead of a LAD) to acquire second languages.

The five psycholinguistic processes of this latent psychological structure which shape interlanguage were hypothesized (Selinker 1972) to be (a) native language transfer, (b) overgeneralization of target language rules, (c) transfer of training, (d) strategies of communication, and (e) strategies of learning. Native language transfer, the process which contrastive analysts had proposed as the *sole* shaper of learner language, still has a major role to play in the interlanguage hypothesis; while it is not the *only* process involved, there is ample research evidence that it does play an important role in shaping learners' interlanguage systems. Selinker (1972, 1992, following Weinreich 1968: 7) suggests that the way in which this happens is that learners make 'interlingual identifications' in approaching the task of learning a second language: they perceive certain units as *the same* in their NL, IL, and TL. So, for example, they may perceive NL 'table' as exactly the

same as TL *mesa*, and develop an interlanguage in which *mesa* can (erroneously in terms of the TL) be used in expressions like 'table of contents,' 'table the motion,' and so on. Selinker follows Weinreich in pointing out an interesting paradox in second-language acquisition: in traditional structural linguistics, units are defined in relation to the linguistic system in which they occur, and have no meaning outside that system. However, in making interlingual identifications, second-language learners typically 'stretch' linguistic units by perceiving them as the same in meaning across three systems. An interesting research issue is how they do this; and what sorts of units are used in this way; for example, they could be linguistic units like the taxonomic phoneme or the allophone, or syllables. Selinker raises questions about the ability of traditional linguistics frameworks, based as they are on assumptions of monolingualism, to handle interlanguage data in which transfer across three linguistic systems plays a central role.

A second psycholinguistic process is that of over-generalization of target language rules. This is a process which is also widely observed in child language acquisition: the learner shows evidence of having mastered a general rule, but does not yet know all the exceptions to that rule. So, for example, the learner may use the past tense marker *-ed* for all verbs, regular and irregular alike: *walked, wanted, hugged, laughed, *drinked, *hitted, *goed*. The overgeneralization error shows clear evidence of progress, in that it shows that the learner has mastered a target language rule, but it also shows what the learner has yet to learn. To the extent that second-language learners make overgeneralization errors, one might argue that they are using the same process as that employed by first language learners.

Transfer of training occurs when the second-language learner applies rules learned from instructors or textbooks. Sometimes this learning is successful; that is, the resulting interlanguage rule is indistinguishable from the target language rule. But sometimes errors result. For example, a lesson plan or textbook which describes the past perfect tense as the 'past past' can lead the learner to erroneously use the past perfect for the absolute distant past—for all events which occurred long ago, whether or not the speaker is relating these to any more recent or foregrounded event, as in the isolated statement, *'My relatives had come from Italy in the 1700s.' These have also been called 'induced errors.'

Strategies of communication are used by the learner to resolve communication problems when the interlanguage system seems unequal to the task. When, in the attempt to communicate meaning, the learner feels that the linguistic item needed is not available to him, he can resort to a variety of

strategies of communication in getting that meaning across. So, for example, if the learner wants to refer to an electrical cord in English and does not know the exact lexical item to use in referring to it, he can call it 'a tube,' 'a kind of corder that you use for electric thing I don't exactly the name,' or 'a wire with eh two plugs in each side.' The linguistic forms and patterns used in such attempts may become more or less permanent parts of the learner's interlanguage.

Strategies of learning are used by the learner in a conscious attempt to master the target language. One such strategy of learning is learners' conscious comparison of what they produce in IL with the NL and a perceived target, setting up interlingual identifications (see the example given above for transfer). Other examples of learning strategies are the use of mnemonics to remember target vocabulary, the memorizing of verb declensions or textbook dialogs, the use of flash cards, and so on. Clearly, such strategies are often successful, but they can also result in error. Memorized lists can get confused with one another, for example, or the mnemonic mediator word may become confused with the TL word. An example of the latter might be that an English-speaking learner of Spanish might use a mediator word *pot* in order to remember that the Spanish word for *duck* is *pato*—but might end up using *pot* in interlanguage references to a duck.

Research evidence was provided to show that all five of these psycholinguistic processes could affect the construction of interlanguages, and a call for more research went out. Many research projects were undertaken in response to this call to investigate each of these hypothesized processes, and the result was a flurry of papers, conferences, and publications, and ultimately something which was referred to as a field of research on second-language acquisition.

1.3 The Relevant Data for the Study of Interlanguage

In his 1972 paper, Selinker stated clearly that the relevant data to be used in the study of interlanguage consisted of utterances produced by second-language learners when they were trying to communicate meaning in the target language. The relevant data were clearly *not* learner utterances produced in response to classroom drills and exercises where the learner was focusing attention on grammar rules or target language form. Just as clearly, the relevant data were *not* the learner's introspections and intuitions about what was grammatical in the target language; such data, according to Selinker, would not provide information about the interlanguage system, but only about the learner's perception of the target language system—and these were different things.

It is important to note that although Selinker was clear about what *he* thought the relevant data of interlanguage study were, there was disagreement on

this point from the beginning. Corder, for example, argued early on and strongly that researchers ought to draw upon a whole range of data sources in exploring learners' language, and learner intuitions of grammaticality were clearly a valuable data source. Others, particularly those investigating the role of universal grammar in SLA, have shared Corder's perspective.

A serious question, however, is this: when one uses different data elicitation techniques in the study of interlanguage, do all those data pools provide information about the same linguistic system? There are, after all, three linguistic systems involved: NL, IL, and TL. If one asks a second-language learner whether a given sentence is grammatical, one cannot be sure whether that learner's response is based upon the NL norm, the IL norm, or the learner's perception of the TL norm; all of these may differ strikingly from the IL norm revealed when one analyzes that same learner's utterances produced in the attempt to communicate meaning. In essence, the most basic research design question involved in the study of interlanguages—what data shall one use to study interlanguage?—raises very complex issues concerning the relationship between intuitions of grammaticality, language production, and language perception, very similar to issues raised by Labov (1970; see *Labov, William*) in sociolinguistic work (see *Applied Linguistics and Sociolinguistics*). This issue is unresolved in SLA research, and in fact is complicated by evidence that interlanguage seems to vary by discourse domain (see Sect. 2.1).

2. Development of the Interlanguage Hypothesis to the 1990s

Soon after Selinker set out the Interlanguage Hypothesis, Krashen proposed the Monitor Model. The Monitor Model initially relied heavily upon the work of a group of researchers (the creative constructionists) who claimed that there was *no* evidence at all of native language transfer in the morpheme accuracy rates of child second-language learners; thus, the contrastive analysts had got it all wrong, at least as far as children were concerned. Where the Interlanguage Hypothesis accords a central role to native language transfer, the Monitor Model does not. The Monitor Model suggests that when second-language learners, adult or children, acquire a second language unconsciously, there will be no evidence of native language transfer; it is only when they consciously learn a second language that transfer effects appear. The study of the role of universal grammar in the process of second-language acquisition, similarly, has tended to downplay the role of native language transfer in that process. One of the contributions of the Interlanguage Hypothesis to the field of second-language acquisition in the 1990s is, thus, a historically-rooted, research-based,

and theoretically-motivated framework for the study of second-language acquisition which can easily account for both the role of native-language transfer and of universal grammar in shaping interlanguage.

2.1 The Revised Interlanguage Hypothesis

By the late 1990s the central claims of the Inter-language Hypothesis remain essentially unchanged, and the intervening years have provided substantial support for them. However, there have been some modifications and expansions since its first detailed proposal in print in 1972. Some of these have been hinted at, and will be expanded upon below.

The original interlanguage hypothesis was restricted to apply only to adults acquiring second languages. However, evidence emerged subsequently that children in language immersion programs, such as the French immersion programs in Canada, also produce interlanguages, in that they evidence apparently fossilized linguistic systems with substantial influence from native language transfer. There appear to be sociolinguistic reasons for this phenomenon; the children receive native-speaker input only from their teacher, and give each other substantial non-native input. They have not usually been given enough opportunity and incentive to produce what Swain calls 'comprehensible output'—attempts to use the interlanguage to communicate meaningfully with significant others. To the extent that these children produce inter-languages in these contexts, there is some question whether they are using their LADs to internalize the target language, or whether they are using those psycholinguistic processes described as more characteristic of adults learning second languages. A great deal more research is needed with this population in order to find out how, if at all, they differ from adult learners.

A second expansion of the IL hypothesis has occurred in response to the growing interest in the influence of universal grammar upon the development of interlanguage. The crucial question here, early on, was this: universal grammar is assumed to be central to the development of natural languages; but is interlanguage a natural language? There have been two positions taken in response to this question. Selinker's initial hypothesis takes the first position: that it is not, at least as the notion 'natural language' has been defined in linguistics. This early position argues: (a) natural languages are produced by language acquisition devices (LADs); (b) language universals exist in human languages by virtue of the way in which the language acquisition device is structured; (c) but interlanguages, unlike native languages, fossilize and evidence native language transfer; (d) interlanguages therefore are a product of latent psychological

structures, not LADs; and (e) so interlanguages do not have to obey language universals. Adjémian (1976), and following him others, took the opposing position that interlanguages *are* natural languages (although, unlike other natural languages, IL rule systems are 'permeable'). As natural languages, interlanguages do have to obey language universals; central to this position is the view that interlanguages are products of the same language acquisition device which produces native languages. In this view, interlanguages fossilize because of complex changes in cases where parameters have already been set for one language, and a second language must be learned. Debate on this issue is certainly ongoing and lively.

A third modification has been a growing emphasis upon something barely hinted at in 1972: the way in which interlanguage development seems to vary in different social contexts, or discourse domains. Increasing research evidence seems to show that learners can produce a significantly more fluent, grammatical, and transfer-free interlanguage in some social contexts than in others. International teaching assistants, for example, may be more fluent and grammatical in lecturing on their academic field than when talking about an everyday topic like favorite foods or bicycling. Key processes such as fossilization may be more prominent for a given learner in one context than in another. This variation in interlanguage production, documented in dozens of studies reviewed in Tarone (1988), is probably related to the problem of data elicitation discussed in Sect. 1.3 above, and certainly has profound implications for data elicitation in research. As suggested above, SLA researchers have argued for the use of a range of elicitation devices in investigating interlanguage. However, if learners do vary at a single point in time in the fluency and grammaticality of the language they produce, depending on variables such as topic, focus on form, interlocutor, and so on, then how are researchers to handle the data they elicit when they do use a variety of tasks? Minimally, when researchers interpret their data, they need to keep the data from each elicitation technique separate, and to keep track of the contextual variables which were in play in each elicitation. Conceptually, this chameleon-like character of ILs raises serious questions about whether and how traditional linguistic notions developed to account only for monolinguals can apply to interlanguages. This is a complex problem for SLA researchers to resolve.

A fourth issue which has occasioned substantial discussion in the literature centers upon the phenomenon of fossilization itself and whether it is inevitable. Selinker argues, essentially, that no adult learner can hope to ever speak a second language in such a way that they are indistinguishable from native speakers of that language. There are inevitable forces which

lead to the cessation of learning. In Selinker's view, there are neurolinguistic reasons for this inevitability. Scovel proposed the Joseph Conrad Phenomenon, in order to draw attention to the very common case where an adult learner's phonological system may fossilize, but the morphology, syntax, and lexicon may not, continuing to develop until reaching full identity with the target language. Scovel (1988), like Selinker, argues that the causes of phonological fossilization are neurolinguistic in nature, and related to the process of cerebral lateralization, which is completed at puberty. But there is certainly disagreement among interlanguage researchers as to both the inevitability of fossilization, and (relatedly) the causes of fossilization. Typically, those who argue that fossilization is caused by sociolinguistic forces (such as the NL group pressure to conform, or one's need to identify with the NL social group rather than the TL social group) also argue that fossilization is not an inevitable process. Such researchers suggest that if learners can identify with the TL social group, or if their need is great enough, they will be able to continue learning the second language until their production/perception is indistinguishable from that of native speakers. This issue also is far from settled, since it relates to matters of human potential rather than humans' actual behavior.

There has been some change in the way in which some of the psycholinguistic processes shaping interlanguage are viewed. For example, native language transfer is viewed as operating selectively; some things transfer from the NL to influence IL, and some things do not. Some crucial questions, therefore, remain: what gets transferred? can we predict in advance what NL characteristics will influence an IL and which ones will not? One promising notion is that of multiple effects: when NL transfer combines with other influences, such as markedness factors, learning strategies, or transfer of training, then there will be greater likelihood of fossilization. So, for example, an early stage of verbal negation common among all second-language learners involves putting a negator (like *no*) before the verb. Learners whose native languages (like Spanish) do negate verbs this way (as in 'Juan no habla' for 'John doesn't talk') will be more likely to fossilize at this stage (producing 'John no talk'). Thus, negative NL transfer has the effect of amplifying the possibilities for fossilization when it interacts with other negative influences. Another psycholinguistic process shaping interlanguage is the learning strategy. A great deal of research has been done (e.g., Cohen 1990), using elicitation techniques such as verbal reports, in order to gain insight into the ways in which learners may consciously set about trying to internationalize aspects of the target language. Some interlanguage researchers have drawn heavily upon the work of cognitive psychologists who have studied the influence of the use of mnemonics on memory. The result of this research has lent itself easily to educational applications, such as the establishment of workshops and even centers to train students in the use of language-learning strategies.

Finally, research of interlanguage has expanded far beyond its original focus on phonology, morphology, syntax, and lexis, to include the sociolinguistic component of communicative competence. Research on interlanguage includes comparative work on the way in which learners execute speech acts across three linguistic systems; Cohen and Olshtain (1981), for example, have studied the way learners attempt to apologize, using their interlanguage, in target language social contexts, and compared this to the way native speakers of both the NL and the TL apologize in the same contexts. Learners' politeness strategies in NL, IL, and TL have been examined on a number of levels by researchers such as Beebe, who have explored miscommunications which have arisen when learners have transferred NL politeness strategies into IL–TL communications.

The Interlanguage Hypothesis provided the initial spark which ignited a field of research on second-language acquisition/learning, and it continues to provide what some feel to be the most productive framework for research. The research questions it originally raised continue to be among the most central and interesting research questions in the field.

Intertwined Languages

P. Muysken

Intertwined languages for a long time have been the subject of heated debate, and in more recent times, as data gathering techniques improved, they have become the object of serious study. The term intertwined was first suggested by Norval Smith, and much work has been done on the subject by Peter Bakker. There is now no doubt that there are intertwined languages, whichever definition is adopted. Three kinds of issues come to the fore in studying them: (a) issues of demarcation and definition; (b) issues of formal properties and structural constraints; and (c) issues of function and genesis.

1. Demarcation and Definition

The question of definition will be approached here in a roundabout manner. In current years there has been an explosion of work in the area of language contact (e.g., Arends et al. 1995, Muysken 2000, Myers-Scotton 1993, Romaine 1995, Sebba 1997, Thomason 1996, 1997). Much of this has been concerned with code-mixing (see *Code-mixing*; *Code-switching: Overview*), the use, within bilingual speech, of two languages in one utterance. Some code-mixed utterances very much look like they belong to an intertwined language, as in examples (1) and (2). Here the italicized inserted elements, glossed bold, are in Dutch, in otherwise Sranan and Moluccan Malay sentences, respectively.

(1) wan heri *gedeelte* de ondro *beheer* fug *ewapende machten*
'One whole **part** is under **control** of armed forces.'
Sranan/Dutch code-mixing

(Bolle 1994: 75)

(2) aku *nog steeds vinden* akan *raar* [kata koe *bellen* aku
1s **still find** it **strange** that 2s **call** 1s
twee keer [*zonder* dapat *gehoor*]]
two time without get **hearing**
'I still find it strange that you called me twice without finding anyone home.'
Moluccan Malay/Dutch code-mixing

(Huwaë 1992)

Intertwined languages differ from code-mixed bilingual speech, however, in at least two ways. In intertwined languages, the mixing is obligatory rather than optional. Furthermore, in code-mixing, the number of elements from a second language is rarely as large as in (1) and (2).

Intertwined languages should also be distinguished from languages with extensive borrowing. Compare utterance (3a) in Media Lengua, an intertwined language with a Quechua morphosyntax and phonology and Spanish root shapes, with utterance (4) in Cochabamba (Bolivia) Quechua, a heavily hispanicized variety of Quechua (a key to abbreviations used occurs at the end of this article):

(3) (a) *uwixa*-buk *yirba nuwabi*-shka
guinea.pig-for grass there.is-not-SD
'There turns out to be no grass for the sheep.'
(b) llama-buk k'iwa illa-shka   (Quechua)
(c) No hay hierba para las ovejas (Spanish)
Media Lengua

(Muysken 1996a)

(4) Chay-manta-qa *niña ni* ima mikhu-na ka-jti-n,
that-AB-TO girl NEG what eat-NOM be-SD-3,

ni ropa ni ka-jte-n-qa *sastre*-mán tukuy ima-ta
NEG clothes NEG be-SD-3-TO, tailor-AB all what-AC

sua-rqa-mu-sqa.
steal-INT-CIS-SD.

'Then when there was nothing to eat, and neither were there any clothes, the girl went to steal everything from the tailor.' Bolivian Quechua

(Urioste 1964)

Even though in (4) all nouns and the negator *ni* are from Spanish, there are quite a few roots from Quechua as well, including the verbs and the function words. In contrast, in (3b) all roots are from Spanish. There is a quantitative leap from 45 percent Spanish roots in heavy borrowing settings to 97 percent Spanish roots in the intertwined language. There is also a qualitative leap from many content words and a few function words (the case of borrowing) to all content and function words that are roots (the intertwined language). In addition, in intertwined

481

languages like Media Lengua the phonetic shapes of the roots are Spanish, while their semantic properties are Quechua. Thus, a new Spanish verb *nuwabi-* is used in (3a), modeled on the Quechua negative existential verb *illa-*. This process is called relexification.

Finally, we should distinguish intertwined languages from spontaneous cases of language mixing, as in the mixed Japanese/English jargon of American Mormon missionaries in Japan, who are practicing their Japanese vocabulary while speaking English:

(5) Hey *dode*, have you *benkyo*ed your *seiten*s for our
       companion   study   scriptures
    sukay today yet?
    meeting
'Hey companion, have you studied your scriptures for our meeting today yet?'
Japanese/English

(Smout 1988)

In contrast to the three language contact phenomena cited so far, the elements from a second language in intertwined languages are (a) systematic; (b) highly frequent; and (c) obligatory. The notion of an intertwined language necessarily then is a diachronic one; the original contributing languages need not be present in the speech community any more in a pure form.

2. Formal Properties and Structural Constraints

If the presence of elements from two languages is systematic, this means that not just individual items from one language are systematically present in another one, but preferably also classes of items. Thus in the Media Lengua example (3a) and in (6), a historically documented example, the roots are from one language, the affixes from another one. (Abbreviations are explained at the end of this article.)

(6) *Heeltemaal*-se *natuur*-a-xu *bedorven*-he   (Basters)
totally-ADV nature-CAS-P rotten-PASS
'totally rotten in nature'
Hoaraga-se =ûb-a-xu gau-he (Nama/Khoikhoin)
Van nature helemaal bedorven. (Dutch)
Basters Hottentot

(den Besten 1987: 23)

However, in Michif, still spoken in parts of western Canada and the neighboring US states, the noun phrases are from French, and the verb phrases are from Cree:

(7) kî-nipi-yiwa *son frère* aspin kâ-*la-petite-fille*-iwi-t
PST-die-OBV.SU 3s.POSS.m brother COMP-the-little-girl-be-3s
'Her brother died when she was a young girl.'
Michif

(Bakker 1997)

In yet other cases, the function words may be from one language, the content words from another,

similar to the code-mixing cases in (1) and (2). What all these cases have in common is a certain asymmetry, analyzed by Myers-Scotton (1993) (see *Code-switching: Structural Models*; *Myers-Scotton, Carol*) in terms of the matrix language/embedded language contrast. The affixes in Media Lengua and Basters Hottentot, as well as the verbal morphology in Michif, may be construed as constituting a functional skeleton for the clausal structure. Thus we can propose the following tentative generalization:

(8) Intertwined languages typically show a matrix/ embedded language asymmetry.

There may well be counterexamples to this, along the lines of Silverstein's (1972) analysis of Chinook Jargon as a multilevel generative system, but they are not frequent. There may be a second possible generalization, which so far has been implicitly in the background; namely that all cases of intertwined languages at least involve systematic lexical mixing. At least lexical elements from different sources are combined, and in addition possibly, but not necessarily, morphological, phonological, and syntactic elements. Thus:

(9) Intertwined languages at least have lexical elements from different sources.

Again, counterexamples are conceivable, perhaps along the lines of the systems drawn attention to by Gumperz and Wilson (1971), where lexicons are distinct but grammatical rules have converged (see *Areal Linguistics*). However, this type of setting generally also involves lexical borrowing.

3. Function and Genesis

Intertwined languages may well have one of three basic functions: they may function as group (mixed) identity markers, as secret languages, and as ritual languages. Group identity languages are e.g., Media Lengua, Michif, and Basters Hottentot. Here the presence of elements from two languages marks the resulting language as reflecting a double identity. Cases of secret languages are the forms of Para-Romani documented by Bakker and Cortiade (1991); here the systematic presence of alien vocabulary made the language incomprehensible to outsiders. Cases of ritual intertwined languages are Ma'a (Mous, in prep.) and Callahuaya (Muysken 1996b). Here the systematic presence of alien vocabulary marks the ritual language as special or sacred. Ritual and secret intertwined languages necessarily are symbiotic (Smith 1995), i.e., spoken in addition to other languages.

As to the genesis of intertwined languages, the psycholinguistic processes involved in their birth are various. On the one hand, these may involve phonetic shapes of lexical items, as in the relexification of Media Lengua. On the other, there may be cases

where processes of code-mixing are frozen and lead to an intertwined language, as in the case of Michif. Whatever process was involved, its outcome was adopted as a fixed code.

Abbreviations in the glosses: AB = ablative; AC = accusative; ADV = adverbial; CAS = case marker; CIS = cislocative (toward the speaker); COMP = complementizer; INT = intensifier; m = masculine; NEG = negator; NOM = nomin-alizer; OBV.-SU = obviative subject; P = postposition; PASS = passive; POSS = possessive; PST = past tense; SD = sudden discovery and narrative tense; TO = topic; 3s = third person singular.

Jargons

P. Mühlhäusler

Whereas in everyday language the term jargon is applied to a wide range of different phenomena, including the specialist register of professionals such as lawyers or sailors, sociolinguists employ terms such as sublanguage, register, or sociolect to most phenomena called everyday jargon. The main technical use of the term jargon is found in pidgin and creole linguistics where it refers to an unstable minimal contact language. Such a variety is unstable both linguistically and socially, showing no consistent pattern of transmission and a tendency to construct the language as the situation requires. Jargons can be located on the idealized continuum of creole development which ranges from jargon to stabilized pidgin, extended pidgin to creole. It is difficult to make nonarbitrary cuts and the boundary between a jargon and a stable pidgin remains ill defined. It seems clear however, that creolization does not require prior stabilization.

Schuchardt introduced the term jargon in a technical sense in 1883. He observed that Philippines Spanish varied from user to user in the extent that Malay influenced Spanish in contrast with the stable situation of Portuguese creole in Macau (Macanese) and Malacca (Kristang). Linguistic instability is a

483

necessary but insufficient attribute for the characterization of jargons. A second one is linguistic impoverishment, i.e., a small lexicon and heavy dependency on contextual information and paralinguistic means of communication such as gestures (cf. Mühlhäusler 1997: 128ff.).

Alternative labels for jargons include 'secondary hybrids,' 'makeshift language,' 'multilingual idiolect,' 'multilevel generative systems,' and the ubiquitous 'broken language.'

Silverstein (1972) emphasizes the macaronic character of jargons, their having multiple grammars, each user group apparently generating sentences from their own grammatical base. Communication is possible because each party strips the complexities of their own grammar and a kind of common core denominator emerges—a strategy that can lead to misunderstanding and communication breakdown.

It has been noted by Ferguson (1971) that the similarities of reduced systems such as foreigner talk or baby talk are much greater than similarities between human languages and it might be that strategies of regression to earlier stages of development is adhered to in communication across language boundaries (see *Foreigner Talk*; *Pidgins and Creoles: An Overview*).

The strategies used when speakers of different languages have to establish verbal communication can vary widely from speaker to speaker with universal transfer and cultural practices such as baby talk playing varying roles. The majority of jargons remain ephemeral, unrecorded, unnamed, and poorly studied. Exceptions are a few longer lasting contact situations, mainly associated with European expansion, which have resulted in jargons such as the Chinook Jargon, Pichingli of the Canary Islands, Tarçanca used by Germans and Turks in tourism, Butler English of servants in British India and Thai Boi of the corresponding group in French Indo-China as well as jargon varieties of Dutch, Swedish, and many others (documented in Arends et al. 1995) that have not developed greater stability in spite of extended use.

Jargons can remain undeveloped or be the first stage of an interlanguage continuum (targeted language learning) or a prepidgin continuum during initial contacts.

The relevance of jargons to sociolinguistics would seem to lie primarily in the complex way in which structural and situational information combines. Records of nonstructural aspects of jargons are rare but with modern recording technology there should be no problems in obtaining observationally adequate data.

Another area deserving sociolinguists' attention is cultural differences in use and tolerance of jargons. Instability, one of their defining features reflects individual solutions to the problems of intercultural communication whereas the emerging stability of pidgins has in part to do with people creating new identities. Mobilian Jargon was unstable only when used between Europeans and Amerindians whilst among different groups of the latter it was a stable Pidgin signaling regional identity.

Impoverishment, again has both an individual aspect—individual learners are in the early stages of L2 learning, but also has a social reason: the topics on which members of different groups are permitted to communicate may be restricted by mutual agreement (in the case of the Hiri Trade language of Papua one was not supposed to discuss women) or by acts of power on the part of one group—foreigners typically are given limited access to esoteric languages. The learning of Danish by non-Europeans appears to have been discouraged by the Danes and no stable pidgin Danish developed in Kristianborg, Gold Coast, or Tranquebar.

The study of jargons raises a number of wider issues including:

(a) The question of the 'locus' of language in individuals or society.
(b) The question of variants and dialects. Are jargons such as Chinook Jargon variants of Chinook or English? This question is particularly important in the case of 50/50 jargons encountered in the early stages of Aboriginal-English contact in Australia (e.g., 'pidgin' Kaurna of Adelaide,) or in the case of Macaronic mixtures.
(c) The question of accommodation and cooperation in conversation—and the extent to which verbal means of communication are involved in successful outcomes.
(d) The question of continuity—in what sense are jargons' earlier stages of later pidgins and creoles and the related matter of?
(e) Reinvention versus diffusion over time and space.
(f) The extent to which jargons reflect innate or natural communication strategies as against culture-specific conventions.

The notion that people communicate because they share a code has come under considerable scrutiny in recent years (Love 1985) and may well turn out to be a much less useful construct than linguists originally assumed. The same can be said for the notion that languages are rule governed, something, which many cognitive scientists no longer subscribe to. Jargons thus may turn out to be at the extreme end not just of the Pidgin and Creole continuum, but extreme examples of the more general human condition that one always has to communicate with others whose knowledge, experience, and ability to express these differs from one's own.

As yet disappointingly little has been done in the area of jargon studies. Instead of further marginalizing them one should see them as a challenge to much current thinking in linguistics and sociolinguistics.

Koinés

R. Mesthrie

The term 'koiné' refers to a language variety that has arisen from contact between dialects of the same language. It originates from koiné, the Greek word for 'common' (in both senses of 'general' versus 'particular,' and 'vulgar' versus 'cultivated'). The term was used in connection with the type of Greek arising in the era of Hellenic unity and the spread of Hellenism (between ca. 450 BCE and ca. 200 BCE).

1. The Greek Koiné

Classical Greek (used up to ca. 300 BCE) had a number of dialects, the main ones being Attic–Ionic, Arcado–Cyprian, Aeolic, Doric, and North-West Greek. Literary dialects took shape from these varieties. (The oldest of these, the Epic or Homeric dialect which goes back to ca. 800 BCE, was an artificial style based primarily on Aeolic, Arcado–Cyprian, and Ionic.) With the spread of Greek influence throughout the Mediterranean region, there arose a tendency toward unification of the dialects. Attic became the form favored by educated Greeks for public discourse.

Thomson (1972) traces the origins of the Koiné to the seaport of Athens, Piraeus, where people from all parts of the Mediterranean mingled. A mixed dialect arose, which was the forerunner of the Hellenistic Koiné (or 'the Koiné') based mainly on Attic, but including elements from Ionic and other dialects.

After Alexander's conquest of Persia (334 BCE), the Koiné became the official language of the Macedonian Empire, which extended as far as the borders of India. Initially it was a second dialect or second language for a majority of its speakers, coexisting in Greece with the other city-state dialects, but no doubt gaining some prestige on account of its association with government and administration. That it was something of an international medium can be seen from its use as the original language of the New Testament, although its composers were largely Aramaic-speaking. Palmer (1980) remarks that the adoption of this Attic-based Koiné by non-Attic as well as non-Greek speakers over a wide area did not lead to profound linguistic change, apart from lexis. The Koiné eventually became a first language, and formed the basis for the modern Greek colloquial dialects.

2. Modern Use of the Term *Koiné*

There is much ambiguity in the modern use of the term, stemming in part from the many properties of the Greek prototype. Each of the following aspects of the original Koiné has been taken as criterial by one or another modern writer:

(a) its development as a new, common variety based on existing dialects of the language (common is taken in the sense of 'shared');

(b) its use as a common (or 'vulgar') medium of communication between speakers with different first languages or speakers from different dialect areas;

(c) its use as the standard/official language of a politically unified region;

(d) changes in its structure on account of its wide use as both first and second language (involving a synthesis of these at some stage).

The Greek Koiné thus embodied formal (a and d) as well as functional properties (b and c). Modern writers show little agreement about which are more basic. One stream of thinking assumes the formal criteria to be primary, leaving the circumstances of origin open; the other takes the use of the language in official or trade domains as primary, and the linguistic characteristics as secondary. The major objection to (b), (c), or (d) alone as a defining

485

criterion is that on its own each defines a language variety or linguistic process that has a well-established label: (b) is synonymous with lingua franca (and the process of language spread); (c) is better described as 'standardization'; and (d) describes the phenomenon of substrate influence in second-language acquisition or in language shift.

For the term koiné to have any significance apart from these three concepts it is necessary to insist on the property of dialect mixing in a contact situation, leading to the development of a new variety. The process of dialect mixing has come to be called 'koinéization,' and the end product of the mixing, a koiné. The importance of criterion (a) over (b) and (c) can be seen in the fact that a speech variety can become a standard language or a lingua franca without necessarily involving koinéization.

Criterion (d) is more problematic. It is not the case that all stable second-language varieties are koinés, nor that koinéization and substrate influences in language shift are synonymous. However, if a number of L2 varieties develop under certain conditions, remain in contact with the superstrate variety, and give rise to a compromise form, then the result may be termed a koiné. Hence some writers have labeled Vulgar Latin a koiné, since it is a synthesis between L1 Latin and related L2 versions. Labeling Vulgar Latin a koiné might appear to contradict the strict definition already offered. This can be easily resolved by allowing the notion of 'related dialects' to include, in special circumstances, L2-influenced varieties arising from language shift.

Given the fuzzy boundary between the terms 'language' and 'dialect,' some flexibility in interpreting the phrase 'related dialects of the same language' is needed. The varieties involved in koinéization should be mutually intelligible for the most part, irrespective of whether they are generally considered different languages or not.

The most salient of the sociohistorical conditions giving rise to koinés (in the narrow sense of (a)) is the convergence of speakers of different dialects (and possibly of some non-native speakers) of a language. Where this takes place in proximity to the original dialects one may speak of a 'regional koiné,' as in the first stages of the Greek Koiné at Piraeus. The opening up of new urban centers may also result in koinéization. In recent world history, however, it is the 'immigrant koiné' which has proliferated, with the movement of speakers of related dialects from one geographical territory to another, often across continents. One might further distinguish between the movements of people associated with colonial powers—administrators, soldiers, missionaries, and settlers—as against subordinate groups moving to fill servile positions in other territories. This forms the basis for a division between a 'superordinate' and a 'subordinate' immigrant koiné.

While the processes involved in koinéization are of considerable interest to the linguist, once a koiné has formed there may be nothing to distinguish it from older dialects of the language. (However, subordinate immigrant koinés do often show a significant reduction in inflections.) Generally, the designation koiné might be appropriate at a particular stage in the history of a language, but loses significance once the variety becomes established as the first language of a new generation. Like any other natural language a koiné may in time develop new regional subdialects, as shown by the history of Greek.

3. Some Examples of Koinés

3.1 A Superordinate Immigrant Koiné—Australian English

The defining feature of this koiné is, as argued above, not that it is the official language of the country or the common language shared by all people of the territory, but that the English developed in Australia shows the effects of contact between various dialects of the UK and Ireland, while not resembling any one in exact detail. Furthermore, the learning of this dialect of English by others in the country (indigenous peoples as well as later immigrants from outside the UK and Ireland) is not a defining characteristic of the koiné since these speakers have not been influential in the koinéizing stage. Australian English is typologically a 'South of England' variety, though the lexical influence of other varieties like Hiberno–English can also be seen. Trudgill (1986) believes its vowel system, probably its most salient characteristic, to be closest to systems characteristic of the vernacular in London and the southeast of England in the eighteenth and nineteenth centuries (for example, the very close Australian vowel in *bid*; [e] in *bed*; [ɛ] in *bad*; and [aː]~[æː] in *path*). Mixing of the features of these dialects probably occurred in Australia, rather than in England itself. This process of koinéization resulted in a new dialect, whose early uniformity has been much remarked upon.

3.2 A Suboridinate Immigrant Koiné—Bhojpuri and Hindi in Former European Colonies

In the nineteenth and early twentieth centuries European colonial powers shipped hundreds of thousands of Indian peasants on indentured contracts to (British) Guyana, Mauritius, Trinidad, Natal, Dutch Guyana (now Suriname), and Fiji. Among people of North Indian descent were speakers of a variety of Indic languages and dialects stretching from the Bay of Bengal well into the interior of northern and central India. The majority of people spoke Bhojpuri (or related varieties) or Awadhi (and related varieties); but there were also speakers of other mutually intelligible forms of eastern or western Hindi, as well as small numbers

Table 1. The past singular of transitive verbs in colonial varieties of Bhojpuri and Hindi, and their sources.

Variety	1st person	2nd person	3rd person
Mauritius	*-lī/-nī*	*-le*	*-lak*
Guyana	*-lī*	*-le*	*-le*
Trinidad	*-lī*	*-le*	*-al*
South Africa	*-lī/-ā*	*-le/-ā*	*-lak/-las/-is*
Suriname	*-lī*	*-le*	*-is*
Fiji	*-ā*	*-ā*	*-ā/-is*

Sources:
1st person: *-lī* Bhojpuri and other Bihari dialects
  -nī some Bhojpuri dialects
  -ā standard Hindi and Awadhi
2nd person: *-le* Bhojpuri and other Bihari dialects
  -ā standard Hindi and Awadhi
3rd person: *-lak* Magahi, Maithili, some Bhojpuri dialects
  -las most Bhojpuri dialects
  -al some Bhojpuri dialects
  -is Awadhi and other eastern Hindi dialects
  -ā standard Hindi

of speakers of distinct languages like Bengali, Rajasthani, Panjabi, etc. In each colony a uniform speech variety developed within a generation, showing the influence of many of the input dialects. In Mauritius, Guyana, Trinidad, and Natal the resultant varieties were closer to Indian Bhojpuri than any other dialect, though they clearly show a blend of features from other sources. In Fiji and Suriname the speech form shows greater resemblance to the interior dialects of Eastern Hindi, especially Awadhi, but the blending of input features is even more clear. In matters of morphological detail, especially, each colonial variety is different from the other and from the parent dialects of rural India. The process of selection can be seen in Table 1, which illustrates the paradigms for the singular of the past tense of transitive verbs in each new koiné, and their sources in Indic dialects:

3.3 A Revived Koiné—Hebrew in Israel

After centuries of use in literary and religious contexts, as no one's first language, Hebrew was proposed for adoption as a vernacular in the 1880s in Palestine. The success of the revival extends to its use as the official language of the state of Israel and as colloquial language of around a million people. Although one particular form of the classical language was aimed at (the Oriental or Sephardic form), general Israeli Hebrew shows influences from the East European (Ashkenazic) and other traditions of pronunciation. The resulting variety, derived from interaction between idiolectal approximations of a classical tongue, has been labeled a koiné (Blanc 1968). Its defining feature is, again, contact between

related versions of the same language (Hebrew), rather than direct interaction between the different languages of the Jewish diaspora. What makes this a very special case, however, is that the contributory dialects were all second-language varieties artificially adapted for use in colloquial domains.

4. Processes of Koinéization

The only necessary process in koinéization (in the strict sense) is that of the incorporation of features from several regional varieties of a single language. In the early stages one can expect a certain amount of phonetic heterogeneity, and possibly differences in phonemic systems, morphology, and syntax. Unification between previously distinct groups (along regional or social lines) results in speech accommodation. The process of accommodation between adult speakers will result in a neutralization of the social meaning attached to linguistic variants. That is, the variation in the early stages of koiné formation will no longer correlate clearly with nonlinguistic factors like region, function, social status, etc. More salient variants will be retained, while minority features will be 'accommodated out.' Forms which are more regular, and therefore more easily learnt (by adults), stand a better chance of being retained. Where several alternatives occur, frequency of a particular form must assume some importance: the more dialects a form occurs in, the greater its chances of survival in the koiné. Accommodation probably does not occur in a haphazard manner: in determining who accommodates to whom, and what forms win out, demographic factors involving proportions of different dialect speakers and relative prestige of groups will clearly play an important role.

In time, as the new town, colony, or region inhabited by new groups begins to assume a new identity, and with the rise of a generation of child language-learners, focusing takes place. Essentially, this results in a reduction of the possible variants of linguistic forms and the stabilization of norms. While accommodation is a characteristically adult process, selection of accommodated forms, and stabilization, are more likely to be associated with child acquirers of the koiné.

These processes are evident in the Bhojpuri diaspora; the illustrations are from the South African variety (Mesthrie 1992):

(a) Variation in the early stages of the koiné can be reconstructed from the speech of isolated rural individuals, whose speech contains morphological markers from some Indian dialects, which are not used in the mainstream of South Africa, Bhojpuri: e.g., a past tense transitive marker *-lis*.

(b) Blending of regionalisms: Whereas Indian Bhojpuri can be broadly subdivided into western and eastern varieties, the distinction

cannot be found in the South African koiné, which is a blend of eastern and western features: e.g., its 3rd person past transitive verb endings follow the easterly pattern, while the 1st person endings follow the more westerly dialects.

(c) 'Accommodating out' of marked, dialect-specific features: e.g., the synthetic negative copula, *naikhĩ*, characteristic of easterly Indian Bhojpuri dialects does not occur in South Africa.

(d) Stabilization and focusing of choices: With few exceptions, regional variants of the parent variety have been leveled out in South Africa. For example, whereas some of the parent dialects have present copula *hai*; others have a form like *bā, bati* or *bānī*; and still others have both *hai* and one of *bā/bāti/bānī*; the South African koiné has only *hai*.

(e) Restructuring of social variation: Gradations in rural dialect pronominal forms and in certain verb paradigms for the purposes of signaling 'respect' have generally been lost in the South African koiné.

(f) Demography: On the whole, the koiné in South Africa has a less westerly character than the one in Fiji, and a less easterly character than the one in Mauritius. This accords well with the patterns of migration, since recruitment of workers to Mauritius occurred first from the northeast regions of India, and then proceeded further into the interior for colonies like Natal (South Africa) and furthest in for Fiji.

Other processes frequently found in, but not diagnostic of, koinéization are simplification, reduction, and stylistic reallocation. 'Simplification' refers to an increase in regularity of structure via-à-vis some other dialects of the language. 'Reduction' denotes the loss of grammatical categories or the development of lexical means of expressing them. These two processes are found in subordinate immigrant koinés, but less so in superordinate ones. Thus, simplification and reduction are uncharacteristic of Australian English, but are present in diaspora Bhojpuri (e.g., simplification in pronoun systems; and reduction in verb paradigms with the nonuse of plural verb forms). 'Stylistic reallocation' refers to the occasional retention of purely regional alternants, with a realignment of functions, one serving as formal, the other as colloquial variant. Thus the *dance* vowel is [a] in northern British English, [æː] in some Midland dialects, and [aː], [aː], or [æː] in the south. The last two forms occur in Australian English, and in the eastern states have social rather than regional significance. That is, [æː] is the more general form, but [aː] occurs in higher sociolects and formal styles.

5. Koinéization in Relation to Other Linguistic Processes

Koinés form a continuum with other types of contact phenomena, some of which they have been erroneously identified with. A brief consideration of the following outcomes of language contact will clarify the essential characteristics of koinéization: dialect convergence; intimate borrowing and code-switching; substrate influences in language shift; convergence; pidginization; creolization.

Dialect convergence denotes a situation in which two or more dialects of a language occur in stable contact along regional or social borders. Mutual influence may occur, without the development of a new variety. Thus, there is no question of koinéization.

In intimate borrowing and code-switching we see the extensive lexical influence of one language upon another. Modern urban vernaculars showing the (primarily lexical) effects of contact between an indigenous language and a world language of prestige (e.g., urban varieties of educated Hindi in India; Town Bemba in the Zambian Copper Belt) have sometimes been labeled koinés. Until genuinely mixed languages of this sort stabilize, there is little need for a new term. In any case, the designation koiné is not appropriate; 'process' terms like intimate borrowing and code-switching will probably suffice.

Substrate influence in language shift: The term koiné has sometimes been used in the context of the acquisition by a community of a second-language associated with a world or regional power, or with trade. The regional language often takes on new characteristics in different regions on account of differential influences from first languages. Thus the Swahili spoken in some parts of Africa (e.g., the central and southeastern parts of the Democratic Republic of Congo) is said to be a koiné. However, the designation koiné is not appropriate for purely second-language varieties. If, in the process of becoming a first language, an L2 retains some features of the former language(s), it is appropriate to speak of substrate influence. It is possible to conceive of a special case where one or more of such substrate-influenced L1's remain in contact with the superstrate variety, giving rise to a new dialect. This has occurred several times in the history of Vulgar Latin, but has to be demonstrated for other putative substrate-influenced koinés.

Convergence of languages which have been in long periods of contact involving widespread bilingualism can lead to mixing at the structural level, while keeping lexicons separate—the paradigm example being Gumperz and Wilson's (1971) study of Urdu–Marathi–Kannada trilingualism in the village of Kupwar in India. One or two writers have considered this kind of convergence to be akin to koinéization,

with the criterion for 'related dialects' generalized to 'typologically similar languages.' However, language convergence of this sort is easily distinguishable from koinéization by the nonappearance of a new variety involving mixing. In Kupwar, for example, the languages have not merged; they continue as three systems, clearly distinguishable at the lexical level.

Pidginization: All writers agree that pidginization involves a far greater degree of simplification and reduction, so that while koinés are structurally continuous with the language varieties they arise from, pidgins are not. The oft-cited condition that a pidgin develops in situations involving more than two distinct languages (i.e., mutually unintelligible or minimally intelligible varieties) is clearly responsible for this state of affairs.

Creolization: Apart from those who link convergence and creolization, few linguists would be tempted to claim similarities between creoles and koinés. The degree of expansion and elaboration that a pidgin undergoes in creolization is not matched in koinéization, since koinéization involves a large proportion of native speakers of the same language from the outset.

6. Conclusion

Although definitions and criteria abound, only the strict sense of koinés being new varieties which develop from mutually intelligible varieties ('related dialects of the same language') is warranted in linguistics. (These dialects may, in special cases, include L2 varieties.) However, other uses of the term persist, which may be better served by labels like 'standard language,' 'lingua franca,' 'official language,' and—less commonly—'language convergence,' 'intimate borrowing,' and 'substrate influence.'

Language Enclaves
K. Mattheier

A language enclave or speech island (German *Sprachinsel*) is a special type of a linguistic minority. As in the case of other linguistic minorities, language enclaves are characterized by the fact that speakers (or groups of speakers) of a dominant language (i.e., the majority language), and speakers of a minority language live together within an administrative and/or sociohistorical unit.

1. Types of Linguistic Minorities

Linguistic minorities can be understood in different ways (see *Minority Languages*). Statistical minorities exist in those cases where there are a certain percentage of speakers of a second (non-dominant) language within a speech community. More important however, is the concept of a sociocultural linguistic minority. This refers to a specific sociolinguistic constellation, which is characterized by the fact that speakers of a different language form a relatively homogenous settlement and a linguistic community within a certain geographical area or territory, and usually show an awareness of their linguistic, cultural, and ethnic identity. Within this constellation one can distinguish two societal types of linguistic minorities. On the one hand, there are those groups, which are linguistic minorities in the strict sense of the term. These are isolated, small (or very small) linguistic communities, which are situated

within the territory of a dominant speech community. Examples are, the settlement area of the Westslavic Sorbian speech community in the southeast of Germany, and the Breton speaking community in the west of France. In these cases there exists no additional political or geographical region where the minority language is spoken (possibly even as a dominant language), outside of the particular settlement area. If however there exists in addition to the minority settlement something like a 'language homeland,' then we use the term 'language enclave' or 'speech island.' Examples of such language enclaves are the Bhojpuri/Hindi speech communities in Mauritius and Fiji, the Venetian/Italian-speaking communities in Mexico, the 'Hunsrückisch' (a Middle German dialect) and 'Plautdietsch' (Mennonite Low German) speaking groups in the south of Brazil and in Russia, and the Pennsylvania Dutch (i.e., German) speaking groups all over North America.

2. General Characteristics of Language Enclaves

The concept of language enclaves or speech islands is particularly common in German linguistics and dialectology, where it has a research tradition of more than 100 years (cf. for example, the investigation of the German-speaking communities in Russia and Siebenbürgen, Romania). The study of the linguistic and historical connections between language enclave and 'language homeland' initially focused largely on questions of ethnic origin. However, more theoretical implications relating to sociolinguistic variation can be detected from as early as Viktor M. Schirmunski's seminal work on the German dialects in Russia during the 1920s. Outside of Germany the relationship between the languages of homeland and the isolated external settlements has typically been considered from the perspective of linguistic minority research. However, there are a number of factors which suggest that it is useful to consider language enclaves as specific types of linguistic minorities. On the one hand, there exist deep historical and social relations between the language enclave and the homeland. Occasionally such relations have been reinstated after decades or even centuries, when—as, for example, in many parts of the US—folkloristic traditions of the homeland are again cultivated. Moreover, there can exist, over long periods of time, on-going immigration from the native country to the language enclave. There are also cases in which the native country fulfills more or less extensive governmental/administrative responsibilities. These can include educational provisions and the supply of teachers for mothertongue instruction, cultural support, and even the legal protection of minority rights. In Germany, these responsibilities are extended to include the right of return for descendants of the original settlers (many of whom had left Germany during the eighteenth century).

Finally, language islands are often characterized by a national or ethnic sense of belonging to the native country. This sense of ethnic belonging can inhibit identification with the new surrounding society (see *Ethnicity and Language*). With regard to the German-speaking minorities in Hungary this has been described as a 'floating identity.'

All these factors are absent in the case of a linguistic minority in the strict sense of the term. Language enclaves and linguistic minorities therefore exhibit different developmental tendencies. However, there also exist situations in which a language enclave largely breaks off contact with the native country after its foundation. In such historical constellations the status of a 'speech island' is conceptually problematic, as in the case of the Pennsylvania Dutch language enclaves which had no contact with their area of origin (the Palatinate in Germany) in 1775.

The origin and development of language enclaves depend on a specific sociohistorical and sociolinguistic constellation, which has so far attracted little comparative research. Such a constellation was given in different areas at certain times during history, such as the large-scale migrations caused by religious conflicts, which took place after 1550 in Europe, or the colonial expansion of European nations in the seventeenth and eighteenth centuries. In all these cases a prerequisite of the process is a motivation of members of a community to leave the social structures of their regional or national homeland as a group. Such motivations can be found in the conditions of the natural environment (e.g., great natural catastrophes) and in the ethnic-political context of the dominant society; moreover they can be of a religious kind or simply economic. The migrations themselves are often based on settlement plans and organized voyages, which significantly shape the settlement structures in the 'new homeland' and which support the formation of ethnic or religious solidarity in a clearly specified territory. The latter constitutes a prerequisite for the development of an independent identity in opposition to the new majority society. Moreover, in the process of establishing the new society one often observes activities of divergence and dissociation by members of the speech enclave as well as by members of the majority society.

Such constellations have been common and are still common in many regions. Examples are the language enclaves of Turkish migrants in Germany or Sweden, and those of South Asian (Indian, Pakistani, Bangladeshi, and Sri Lankan) or Caribbean groups in England. In most of these cases, the language enclave only survives for a limited time and the development usually concludes with the abandonment of the heritage culture. For example, most of the many Middle-Low German language enclaves which had emerged since the fourteenth century due to the activities of the *Hanse* (an important trade

organization) around the North Sea and the Baltic Sea, had already disappeared in the eighteenth century.

3. Definition and Research Perspectives

Taking into account the considerations outlined in the previous section regarding the general socio-historical and sociolinguistic conditions of the phenomenon 'language enclave,' the following definition can be formulated:

> A language enclave (or speech island) is a communication community which is separated geographically from its 'language homeland,' and exists as a linguistic minority within a linguistically/ethnically different contact society, whose language dominates within the territory (German *Überdachung*). The language enclave keeps itself apart from the contact society (and is kept apart by the contact society) because of a number of objective characteristics or factors which define the special status of its members. This supports the emergence of a special sociopsychological disposition or mentality of the language enclave, which can explain the prevention or retardation of full linguistic-cultural assimilation to the contact society.

Within the language enclave we thus find a number of objective factors (circumstances and influences) which work together in creating what one might term a 'language enclave mentality' or a 'language enclave identity' among the members of the community. The existence of a 'language enclave consciousness' is the reason why the normal process of intergenerational assimilation to the foreign language of the new environment is interrupted or retarded. Outside of language enclave constellations, this process of linguistic-cultural assimilation and acculturation usually takes place within three or four generations (see *Language Maintenance, Shift, and Death*).

The comparative study of language enclaves—also in contrast to linguistic minorities in the strict sense of the term—should focus on exactly this relationship, that is, on the combination of a number of objective (i.e., economic, demographic, administrative, and general social) factors and the developing ideas of an identity within a language enclave, which make possible the separation from the outside world. Furthermore, research should study the reactions of the contact society towards these developments. For example, in many of the economically motivated, rural, dialect-dominant, German language enclaves in the US and Canada, the use of three varieties (a German dialect as well as the German standard language and—within limits—English) had consolidated by the late nineteenth century. There were hardly any signs of language shift and several indications of the development of a local German-American language mentality. The spread of industrialization into the rural areas and especially the outbreak of World War I shattered this identity; the process of linguistic assimilation towards American English started with increasing force, and came to an end in most language enclaves three generations later.

The selection of the range of objective factors, which are crucial for the formation, and development of a language enclave has been debated time and again in the literature (cf. Clyne 1985, 1994, Kloss 1966). In these discussions several language maintenance factors have been emphasized. Of central importance is the field of demography, in particular in connection with the language and variety profile within the language enclave and its environment. It is not entirely clear in this context how small language enclaves can be with regard to their demographic structure. One also needs to pay attention to the regional expansion of language enclaves, especially their degree of compactness. Pennsylvania Dutch-speaking groups in the central counties of Pennsylvania never constitute a group of more than 18 percent of the total population. Thus one cannot speak of a compact settlement. Other formative influences can be found in the economic structure, the legal-administrative structure, the social structure (such as the degree of endogamy), and the sociolinguistic structure of language and variety use. First comparative analyses of these factors and their effect on language maintenance and language loss show that, for example, in the German-based language enclaves language maintenance is indicated reliably by only one factor: the religious orientation of Anabaptist groups. Only within the conservative groups of the Old Order Amish, the Mennonites, and the Old Colony Mennonites, which live in isolation from 'the world,' is the local dialect (Pennsylvania Dutch and Plautdietsch, respectively) not endangered. Language maintenance factors other than those linked to the field of religion are of little relevance when assessing the development of these language enclaves. On the other hand, it is methodologically difficult to adequately understand phenomena such as language enclave identity or mentality. Here comparative analyses of diverse language enclaves with different heritage languages and contact or target languages can help to refine our theoretical ideas and to differentiate between different language enclave constellations.

Language Loyalty
R. Mesthrie

Language loyalty is a term one occasionally encounters in the literature on language maintenance and shift. That it is intended in a non-technical, self-evident sense is evidenced by the lack of a definition in books and articles carrying the term in their titles. The term was first used by Fishman, a pioneer in the field of language maintenance and shift (see *Fishman, Joshua*; *Language Maintenance, Shift, and Death*). His book *Language Loyalty in the United States* deals with 'the maintenance and perpetuation of non-English mother tongues by American ethnic and religious groups' (to quote its sub-title). Fishman (1966: 15) does not define the term 'language loyalty,' but styles the book as 'a study of the self-maintenance efforts, rationales, and accomplishments of non-English speaking immigrants on American shores.'

As such the term loyalty may be taken to be the impulse behind language maintenance (or its opposite, shift). Indeed Fishman (1966: 21) writes that 'language maintenance, prompted by one or another variety of language loyalty has frequently been a component—and, at times, a catalyst' in the efforts of ethnic minorities to maintain themselves. Fishman's own work and that of his successors makes it clear that the equation 'loyalty = maintenance; disloyalty = shift' would be simplistic and incorrect. The reason for this is that the term loyalty itself covers conscious, practical manifestations (e.g., recognizing the danger of shift and setting up counter-measures like special language classes outside mainstream schooling) as well as more vague and unconscious attitudes which underlie language choices (see *Attitudes and Behavior*).

In many communities undergoing shift loyalty to the ancestral language is frequently avowed overtly; yet unconscious (or covert) language choices made by community members often favor the incoming dominant language. The terms 'overt' and 'covert' are here borrowed from the better known dichotomy set up by Labov (1972) between overt and covert prestige to explain why, despite openly articulated professions of the superiority of a standard or dominant variety, speakers of a (stable) vernacular (see *Vernacular*) nevertheless are happy to persist with their lower status speech within their own social networks. In her study of language shift from Gaelic to English in East Sutherland, Scotland, Dorian (1981: 104) noted that such a conflict between attitudes and behaviors:

> It is *not* acceptable to behave as though one did not know Gaelic oneself, but it *is* acceptable to do nothing to see that one's children know it.

It would probably be a case of blaming the victim to style such behavior as disloyalty: rather it seems a mix of 'symbolic loyalty' (to the ancestral language) with pragmatic allegiance (to the dominant language). In language shift we thus have a reversal of the roles of 'overt' and 'covert' prestige, with overtly stated allegiance to a (lower status) ancestral language accompanied by covertly sanctioned use of the dominant language (the new vernacular). The variety that once had covert prestige now has attachments of 'symbolic loyalty' (or overt professions of worth and prestige).

This is perhaps an oversimplification of the complex and frequently poignant dynamics of language shift (see *Language Maintenance, Shift, and Death*), but it is necessary to unpack the implications of the term 'language loyalty' which turns out to be more complex than the lay sense after all. Language loyalties may underpin maintenance efforts but are in some circumstances also outcomes of the maintenance-shift dialectic. Speakers readjust loyalties according to changing power dynamics of the linguistic market (see *The Linguistic Marketplace*). Loyalty therefore seems destined, like its counterpart 'prestige' in sociolinguistics (to which it is closely tied) to remain a useful but undertheorized term.

Language Maintenance, Shift, and Death
R. Mesthrie

Language shift and death are overlapping terms used to describe situations in which a language ceases to be used by a speech community. *Language shift* occurs when a new language is acquired by a community with the concomitant loss of its erstwhile primary language. If that community is the last (or only) one to use the obsolescent language it is possible to speak, in addition, of language death. *Language death* may also describe a situation in which a language is lost without a new one replacing it. This is occasioned by the destruction of the speech community itself. *Language maintenance* denotes the continuing use of a language in the face of competition from a regionally and socially more powerful or numerically stronger language.

1. History

The extinction of Cornish in England in the eighteenth century is an example of language death as well as shift (to English). The demise of an immigrant language like Norwegian in the USA exemplifies shift without death, since the language survives in its original setting in Norway. (Some commentators might, however, speak of the death of this immigrant dialect of Norwegian.) Language death without shift is exemplified by the fate of Tasmanian, whose speakers were almost entirely wiped out just 73 years after the first contacts with British settlers in 1803. The last speaker of Tasmanian is said to have died with her own language intact, and with no knowledge of English, save for a few loanwords (Swadesh 1948).

Although, in popular parlance, languages like Latin, Ancient Greek, and Sanskrit are referred to as dead languages, this use of the term is inapplicable within the framework of this article. Languages like these gradually evolved by continuous intergeneration transmission into dialects which gave rise to autonomous and eventually standardized speech forms. At no stage was there a sharp break from one colloquial speech system to another. On the other hand, it is accurate to speak of the death of ancient languages like Pictish, Etruscan, and Gothic.

Hebrew provides the unusual example of a language which did die as the medium of everyday conversation, but was revived with considerable effort in the late nineteenth and early twentieth century.

It is estimated that in the period 1490–1990 about half of the world's languages disappeared. However, one scholar (Brenzinger 1992) is of the opinion that for East Africa, at least, language shift and death are not necessarily more frequent today than before—they have been side effects of migrations and expansions of ethnic groups over the last 5000 years.

In the last twentieth century, Aboriginal languages of Australia were greatly in decline. It is estimated that of the 200 languages of precontact Australia, fewer than 50 have viable communities in which children are able to speak the language. In the USA the fate of Amerindian languages is not much better, although at least one language—Navajo—is thought to have had as many speakers at the close of the twentieth century as it had at any stage of its history. (However, allowing for population growth and the fact that not all children from the community are acquiring Navajo, there seems little room for complacency.) In Europe the Celtic languages struggle to survive against English and French. In Southern Africa languages of the Khoi and San families have been the victims of shift and death. Generally, minority languages on the African continent have given way to other more prestigious African languages rather than languages of European colonialism.

2. Causes of Shift

For a large number of cases involving indigenous languages in Australia and the Americas the causes of shift and death are clear. Once viable and autonomous speech communities were either destroyed or deprived of their traditional land and resettled with other groups who did not always share the same language. Eventual reorientation to a new westernized society further attenuated the viability of traditional forms of the surviving languages among the young (see *Endangered Languages*).

It is one of the few points of agreement in studies of minority and immigrant languages that there is no single set of factors that can be used to predict the outcome of language maintenance efforts. Causes of shift are generally multiple and interrelated. Kloss (1966) has pointed out that many of the factors may even cut both ways. Thus, no uniform or predictable consequences for language maintenance or shift are derivable from (a) absence or presence of higher education in the dominated language, (b) relatively large or relatively small numbers of speakers of the dominated language, (c) greater similarity or greater dissimilarity between groups speaking the dominant and dominated languages respectively, and (d) positive or hostile attitudes of the dominant group to the minority.

The factors that are most often discussed in individual cases of shift can be grouped as follows: economic changes; status; demography; and institutional support.

2.1 Economic Factors

Economic changes are by far the most salient of the factors leading to shift, though the relation is neither necessary nor sufficient. The juxtaposition of different speech communities is frequently brought about by invasion, seeking of refuge, immigration of workers, or trade. All of these (except, perhaps, for refuge) have an underlying economic motive. In many countries modernization, industrialization, and urbanization often lead to bilingualism in a vernacular language and a more widespread regional language associated with the economy. In conjunction with other factors (discussed below) these may lead to shift.

Jones (1981) traces the beginnings of language shift in Wales to the creation of an upper ruling class from the Tudor period onwards, which became increasingly Anglicized as it grew more and more drawn to the social, economic and cultural sphere of London. The second phase in the decline of Welsh involved immigration of English speakers into the coalfields of south-east Wales in the second half of the eighteenth century. With respect to Scots Gaelic, Thomson (Haugen et al. 1990) argues that the exodus of people from the Scottish Highlands in search of work in English-speaking areas in the nineteenth century was a key factor in its eventual decline. Economic factors thus counteracted the efforts of the Gaelic Schools Society to foster stable Gaelic–English bilingualism.

Less commonly, economic changes can positively affect a threatened language. Paulsen (1981) describes the case of the Ferring dialect of Frisian spoken in the North Sea islands of Föhr and Amrun. After the decline of traditional herring fishing a school was founded in the sixteenth century to teach navigation skills to boys, who subsequently found employment in the new Dutch overseas shipping companies. Speaking Ferring was an advantage and immigrants had to learn it if they wished to become members of this closed seafaring community. This was one of the main factors enhancing maintenance of a previously threatened language.

2.2 Demographic Factors

Numbers of speakers do have a bearing on successful language maintenance: it might seem obvious that the smaller the size of a community, the stronger the threat of language shift and death. However, it is not possible to specify a 'critical mass' of speakers necessary for the survival of a language. Brenzinger et al. (1991) cite the case of Bayso, an Eastern Cushitic language of southern Ethiopia, which has resisted language replacement for over 1000 years although the number of its speakers has always been small (in 1990 in the region of 500).

Apart from absolute numbers, or proportions of speakers of dominated language to dominating

language, the distribution of speakers is of some significance. Enforced or *de facto* segregation of immigrant communities would appear to offer better chances of language maintenance, all other things being equal. Li (1982) found that third-generation Chinese Americans residing in Chinese-dominant neighborhoods ('Chinatowns') were less likely to have adopted English as their mother tongue than their agemates outside the Chinatowns. Endogamy within an immigrant group will also improve chances of a family language being transmitted to offspring. Brenzinger cites intermarriage between the Yaaku and Maasai of north central Kenya as one of the main factors leading to a shift in economic practices among the former (from hunter-gatherers to pastoralism), and to an eventual shift in language.

2.3 Institutional Support

The use of a minority language in education, religion, the media, or administration may assist attempts to bolster its position. But for minorities, this can only be done at great cost. There are limits to the extent to which a nondominant immigrant language (or, more usually, languages) can be used in schools. A majority asymmetry exists between use of a minority language in educational settings (associated with formal and standard norms of a language) and the hypercolloquial and localized use characteristic of a language in its dying stages. The role of German in the religious sphere among the Old Order Amish and Mennonites is considered to be a primary cause of maintenance of Pennsylvania German, though other factors are also implicated (endogamy, resistance to economic and social change, etc.). For many communities religious activities demand an archaic form of their language or a register far removed from colloquial speech.

2.4 Status

Some writers consider a group's self-esteem and the status of their language (oral or written, vehicle for scared texts, major regional language elsewhere in the world, etc.) to play a role in maintenance or shift. These are not entirely separate from economic and class factors, however. Thus, Arabic is a high-status language in the Middle East, but not in Europe, where it is mainly connected with immigrant working-class speakers.

In his review of the field, Fishman (1972) emphasizes the ambivalence of generalizations that might seen to have obvious validity. Thus, language maintenance is not necessarily a function of intactness of group membership, particularly of such ideologized expressions of group loyalty as nationalism. Urban dwellers are not necessarily more prone to language shift than rural dwellers. It is not always the case that the more prestigious language displaces

the less prestigious one. Women may be in the rearguard of shift in some instances, men in others.

3. The Course of Shift

It is obvious that a shift from one language to another cannot be effected without an intervening period of bilingualism. In the initial phases of the relationship the languages may show characteristic distribution patterns over specific domains. More formal domains may, by force of circumstances, be allotted to the dominant societal language; more informal domains like the home to the minority language. Language shift involves the progressive redistribution of the languages over these domains—the home, religion, folk songs and tales usually being the last bastions of survival for the dominated language.

Many shifts involve more than one minority language, whose positions are weakened not only by the dominant language but by each other. Immigrant communities from different areas of origin may develop close associations in the workplace and neighborhood, which demand the use of a lingua franca. The most expedient or neutral choice is often the dominant societal language. A similar ethos among different Amerindian groups in the USA, and Aboriginal groups in Australia forced into reservations, has accelerated the pace at which English developed as a lingua franca, often to the detriment of the indigenous languages.

The process of shift is often gradual, involuntary, and unconscious. While the circumstances of the shift may be centuries in the making (as with Welsh, Irish, Scots Gaelic, etc.), there are instances of languages which have been demographically stable for several centuries experiencing a relatively rapid shift. Dorian (1981: 51) (see *Dorian, Nancy*) characterizes this as a sudden 'tip,' after which the demographic tide flows strongly in favor of some other language. Two examples recently cited include the tip from Nubian to Arabic in Egypt, and from Scots Gaelic to English in Cape Breton, Nova Scotia in the 1930s and 1940s.

Leap (1981) believes that there have been no instances, historical or contemporary, where an Amerindian community has intentionally allowed ancestral language fluency to disappear. Although this would appear to be the general norm worldwide, there have been a few instances of shift which have been deliberately hastened by members of the speech community. Eidheim (1969) discusses the case of the Saami fjord community which aspires to full participation in the public network, as it is defined by Norwegians. Many families have taken the drastic decision of preventing their children from learning Saami. Brenzinger et al. (1991) describe the conscious decision made by the Yaaku of East Africa in the 1930s to give up their language in the face of social, economic, and linguistic pressure from the dominant

Maasai. After adopting the value system of the pastoralists, the Yaaku considered the Maasai lifestyle and their language to be superior and to have higher prestige than their own 'hunter-gatherer' language. They discouraged the use of the old language even within their own community, insisting that the Yaaku language with its semantic emphasis on hunting was unfit for a cattle-breeding society.

The shrinkage of domains in the course of shift is paralleled by receding generational competence in the outgoing language. In its last stages speakers may exhibit an age-graded range of competence from full command to zero. In between these are the competences of young fluent speakers, semispeakers and passive bilinguals (Dorian 1981). *Young fluent speakers* are those who have native command of the ancestral language, but who show subtle deviations from the fluent older speakers' norms. *Passive bilinguals* have full receptive skills in the ancestral language, but are unable to use the language in productive speech. *Semispeakers* are those who have had insufficient exposure to the ancestral language, but continue using it in an imperfect way some of the time, out of a high degree of language loyalty. Dorian characterizes the semispeakers of Gaelic in East Sutherland, Scotland, as having relatively halting delivery, speaking in short bursts and exhibiting linguistic deviations of which older speakers are mostly aware. On the other hand, they are able to build sentences and alter them productively, a trait which distinguishes them from the passive bilinguals.

Other scholars draw finer distinctions between reasonably fluent semispeakers (who are still able to interact with older speakers despite lack of full proficiency) and weak semispeakers or terminal speakers (whose interaction arises mainly out of necessity of clarifying things for older monolingual speakers, rather than out of language loyalty). A finer distinction can also be made between passive bilinguals and 'rememberers.' The latter exist in the last stages of shift, when a group of older fluent speakers no longer exists with whom to exercise their receptive and productive skills. That is, passive bilinguals interact within the community of ancestral language users, rememberers cannot.

Some language death situations give no evidence of the semispeaker phenomenon. Swadesh (1948) reports on the extinction of the Yahi language of northern California, whose last speaker's competence he characterizes as 'flawless.' This man, Ishi, learnt English only in his last years, after being taken to the University of California in 1911. The Californian languages, Luiseño and Cupeño, whose obsolescence involves shift and death, apparently have no semispeakers. People either speak fairly well or not at all (Dorian 1981: 115). The emergence of semispeakers might seem to hinge on the rapidity of death or shift: protracted shift allows for semispeaker

competence (and a command of the new language): rapid shift (or 'tip') and death do not. However, this generalization, like much else in the field, admits of many exceptions—Luiseño and Cupeño are cases in point (languages with a relatively protracted period of shift, but no semispeakers).

Dorian attributes the existence of semispeakers (rather than young fluent speakers or passive bilinguals) in East Sutherland to the following factors.

(a) Late birth order in a large, relatively language-loyal family. In such a family the eldest might emerge as a fluent speaker, whereas the last two or three children may emerge as semispeakers. Although their parents might continue addressing the last two or three children in Gaelic, the influence of elder siblings who bring back English from the school and play ground is stronger.

(b) A second factor is strong attachment to one or more grandparents (most often a grandmother), who usually use far more Gaelic than one's parents. Less commonly, it is the influence of aunts and parents that encourages the semispeaker phenomenon.

(c) Temporary absence from the community often fosters a reawakening of loyalty to the dominated language, which may be first achieved as semispeech if there are fellow exiles who share those feelings.

(d) An inquisitive and gregarious personality might also lead some young people to participate in conversations with elders in Gaelic. Presumably, such outgoing individuals actively wish to conduct conversations in the preferred language of the other party, irrespective of the possible stigma of their own errors.

4. The Linguistics of Obsolescence

Where the actual effects of incomplete acquisition histories on linguistic performance are concerned, equal diversity is found in case studies. An early hypothesis was that dying languages might undergo many processes reminiscent of pidginization. In dying languages and pidgins, for example, vocabulary is relatively restricted, inflections are simplified or generalized, and movement rules lost. A preference for more analytic syntax (compared to the base languages) is another common feature of pidgins and dying languages. Pidginization often involves a degree of language mixing that was thought to hold for semispeaker speech as well. A second hypothesis saw semispeech as a kind of creolization in reverse, since pidgins become creolized by entering into the primary socialization of children, whereas dying languages

case to be used for primary socialization (see *Pidgins and Creoles: Models*).

The pidginization hypothesis has not stood up to close scrutiny. Unlike pidgins, dying languages do not show a tendency to uniformity in word order. Nor are there any reports of the kind of wholesale breakdown of morphology in dying languages that one finds in pidgins. In connection with dying East Sutherland Gaelic, Dorian maintains that allomorphic variety does not undergo substantial change (see below), that word order is unchanged, embedding handled with ease, and certain categories which have marginal or indirect semantic significance persist. None of these is suggestive of processes of pidginization.

Dressler (1972) suggests that languages die on account of rule loss, rule simplification, and the like. Denison (1977) rejects this line of reasoning, claiming that languages become obsolete when speakers no longer deem it worthwhile to communicate with children in a particular variety, and children are no longer motivated to acquire an active competence in that language. In the same vein, Mohan and Zador (1986) place a question mark over exactly when a language may be said to be dead, claiming that the language of semispeakers is not the prelude to death, but the visible signs of an event that has already come to pass. They suggest that the biological metaphor of death is apt in implying a state, not an ongoing process and that languages die intact and earlier than suggested by other writers.

Part of the controversy, and other inconsistencies in pinpointing the characteristics of semispeech, can be resolved by taking into account the amount of exposure that the semispeaker has had to the ancestral language as a child, and of opportunities for its use early on. As Menn (1989) emphasizes, a learner who has encountered the language in question through heavy exposure to ritual language will display rote or formulaic language, but rarely preconventional speech involving overgeneralization of words, morphemes, and constructions. A learner who has had good exposure to the ancestral language till school-going age, and little further opportunity, will lack a formal register in that language. Such speech can be expected to lack embedding and other constructions that are rare in care-taker speech. On the other hand, overgeneralization of morphemes by analogy is to be expected.

Some characteristic features of individual dying languages will now be considered. These must be taken as examples of individual out-comes, rather than of a grand design. One of the problems facing researchers is that the kinds of changes that dying languages undergo are not qualitatively different from ordinary, contact-induced change in

'healthy' languages, and even from language-internal developments, in noncontact situations. It is the quantity of such changes in a relatively short timespan in dying languages that is the distinguishing factor.

Breatnach (1964), describing obsolescent dialects of Irish, claims that the effects of disuse are evident at all stages mainly in the vocabulary, and secondarily in morphological, phonological, and syntactic patterns. The purely phonetic character of the language resists influence to the end.

Dorian's (1978) characterization of the morphology of East Sutherland Gaelic will be taken as a more detailed exemplification of the linguistics of language obsolescence. Among the ways of forming the plural of nouns in the traditional dialect of the area are the following:

(a) Suffixation of the ending -*en* to some nouns
(b) Final mutation (e.g., $t^h \rightarrow \check{c}^h$)
(c) Suppletion (e.g., $t^h\varepsilon$ 'house' (sg) versus $t^h ro{:}r$ 'houses')
(d) vowel alternation (e.g., mak^h 'son' (sg) versus mik^h 'sons')

There are still other ways of forming the plural of specific nouns, involving combinations of the above processes (e.g., final mutation plus suffixation; vowel alternation plus final mutation plus suffixation, etc.).

In semispeaker performance some degree of simplification is present. There is the notable rise of suffixation (especially the use of a 'favored' suffix by individuals), which leads to grammar simplification. However, a great deal of the original complexity remains. Final mutation, vowel alternation suppletion, quantity change, subtraction, and zero formation are still in use among semispeakers, though to a lesser extent than among fluent speakers. Dorian (1978: 608) concludes that 'East Sutherland Gaelic may be said to be dying, at least with regard to noun plurals and gerunds, with its morphological boots on.'

Mithun (1989) outlines the characteristics of an obsolescing polysynthetic language—Cayuga (an Iroquoian language) of Oklahoma. There is a shrinkage of the lexicon, with specific terms being lost before more general ones. Words for objects no longer observed have been forgotten (e.g., animal terms like 'moose,' 'beaver,' 'mink,' 'weasel'). Other changes that do exist in obsolescent Cayuga are quite subtle. Although the inventory of affixes is unchanged, speakers rarely combine several affixes within a word. The reluctance to combine morphemes within single words extends to noun incorporation. In terms of phonology and syntax there are no major changes, leading Mithun to remark upon the nearly complete retention of an amazingly complex morphological and phonological system under limited opportunities to use it.

5. Conclusion

Studies in language maintenance and shift are clearly of great importance, for their potential to contribute to language planning on a societal level as well as for theoretical linguistics. The experience of sociolinguists in this area can be used to help beleaguered language communities to stabilize their languages in the face of the encroachment of major regional and world languages (see *Salvage Work (Endangered Languages)*). From the internal viewpoint of linguistics, the study of dying languages has insights for the historical linguist concerned with substrate influences in language change. Furthermore, the study of semispeech has the same potential to contribute to linguistic theory as other instances of marginal language use—aphasic speech and pidgins. This potential has yet to be fully realized.

Language Spread
R. Mesthrie

The term *language spread* was used by Cooper (1982: vii) (see *Cooper, Robert Leon*) to denote a process whereby the 'uses or the users of a language increase.' More formally he defines it as 'an increase, over time, in the proportion of a communication network that adopts a given language variety for a given communication function' (1982: 6). In modern times this phenomenon applies to languages like English, French, Spanish, Swahili, Russian, Amharic, Hindi, and many more. Such languages are known as 'Languages of Wider Communication' (or LWCs for short). In eras gone by language spread applied to Sanskrit, Greek, Latin, Arabic, and so forth. 'Language spread' is a rather apolitical way of describing what is often the result of language imposition by a greater power, creating new linguistic relations in particular territories (Phillipson in press). It is also somewhat metaphorical insofar as languages cannot spread without human agency and a degree of acceptance (or tolerance) by human subjects. However, since not all cases involve political force or coercion but may involve relatively peaceful diffusion (as with the increase of uses and users of Tok Pisin in Papua New Guinea) the term is perhaps a useful one.

Wardhaugh (1987: 6) stresses that a necessary (but not sufficient) condition for a language to spread is that there be the geographical opportunity for one language to spread into the traditional area of another language or languages. These opportunities may be provided by rivers, seas, or traditional trade routes and in the modern era by air travel. Tourism for example may afford niches for some dominant languages, even if there hadn't been colonial domination previously. The Ancient Greeks spread their language via colonization of the Mediterranean area (see *Koinés*), which typically in colonization came to represent authority and administration, but also culture and religion. Wardhaugh (1987: 6) discusses the case of Amharic as follows:

> In the nineteenth and twentieth century speakers of Amharic spread themselves through Ethiopia largely as a result of military conquest but it was the availability of road systems and towns on those systems that enabled them to spread their language and consolidate the position in the newly acquired domains.

Once imposed by colonization or military conquest a language may remain in an area well beyond the term of conquest. Post-independent African states find it

useful to retain a European colonial language like French, Portuguese, or English for certain functions. The field of language spread is clearly an important one for sociolinguistics and political sociology. It is also of some significance in historical linguistics (see *Borrowing*; *Language Transfer and Substrates*). Cooper had hoped to found a coherent theoretical area within sociolinguistics that would examine what individual cases of spread have in common:

> What are the psychological, social, and linguistic phenomena which, in interaction, account for language spread? Do languages spread in the same way as single items of vocabulary, pronunciation, or grammar? Do languages spread according to the same laws of innovation more generally? (1982: 5).

Such questions remain largely unanswered. One reason for this is that the questions may be too broad and ambitious. Sociolinguists have thus concentrated on more specific aspects of the field, as the discussion of the following topics in this encyclopedia will show: *Linguistic Imperialism*; *Language Conflict*; *Linguicide*; *New Englishes*; *Language Diffusion Policy*; *Contact Languages*; *Pidgins and Creoles: An Overview*.

Language Transfer and Substrates
T. Odlin

1. Introduction

Terms such as *language transfer* and *cross-linguistic influence* often denote myriad factors at work when either the native language or some other previously (and perhaps imperfectly) learned language affects the acquisition of a new language. (The use of *native language* henceforth should be understood as shorthand for any previously acquired language.) Other recently used terms denoting more or less the same phenomenon include *mother-tongue influence* and *substrate influence*, with the latter especially common in discussions of cross-linguistic influence in historical studies of language contact, as seen below. Whatever the descriptor employed, the phenomenon designated is distinct from other types of cross-linguistic influence including cases where a second language affects knowledge and/or use of one's native language (sometimes called *borrowing transfer*) and cases of code switching among bilinguals highly proficient in two different languages. Still two other terms sometimes used to characterize the phenomenon of language transfer are *language mixing* and *interference*, but both have serious drawbacks. Although the effects of one's native language on the acquisition of a second can indeed be seen as mixing, so can borrowing transfer and code switching. The notion of interference likewise seems applicable in undesired cases of borrowing transfer as well as in undesired influence from the native language. A further problem with the term *interference* is that it implies a psychological construct distinct from what sociolinguists sometimes call *convergent influences*, as when, for example, English learners of French note the lexical similarity between *difficult* and French *difficile*. In second language research, such convergences are often called *positive transfer*, as opposed to *negative transfer*. Even though the latter two terms have their liabilities, they correctly suggest that the underlying psychological factors involved in the two kinds of transfer have something in common.

The use of *positive transfer, negative transfer*, and simply *transfer* has sometimes led linguists to conclude that such notions are necessarily linked to some form of behaviorist psychology. However, the use of *transfer* as a term and a concept independent of behaviorism goes back to the nineteenth century and continues to the present. Apart from the behaviorist controversy, work on language contact and second language acquisition has had no shortage of people skeptical about the reality or the

499

importance of cross-linguistic influence. When controversies about such influence do arise, three arguments are often made either implicitly or explicitly:

(a) Psycholinguistic argument: transfer is (sometimes) impossible.
(b) Sociolinguistic argument: (individual) transfer will not alter the language of a speech community.
(c) Methodological argument: transfer is (sometimes) impossible to determine.

As Odlin (1992) notes, the strong form of each of these arguments—the versions when the parenthetical qualifiers are dropped—is not at all credible. At various points to follow, evidence refuting the strong forms of the first two arguments will appear, and the next section will take up the issue of methodology. On the other hand, the weaker form of each argument can be true in particular language contact situations, and the plausibility of the 'weak' arguments in these situations show many of the difficulties inherent in developing a thoroughly satisfactory account of substrate influence.

2. Methodology

A good understanding of the neurological basis for cross-linguistic influence seems a long way off, but facts about the performance of second language learners leave no doubt about the reality of such influence—or about the existence of a sound methodology to determine such influence. The acquisition of English in Finland has offered a convenient, though not unique, opportunity to employ convincing methods. One book-length study of the Finnish situation (Ringbom 1987) compares the performance of two groups having highly different native languages: Finnish and Swedish. The vast majority of Finnish citizens (some 93 percent) speak the former as their mother tongue although a minority of about 6 percent speaks Swedish. While speakers of both languages often learn some (often a great deal) of the language of the other community, the native language difference shows up clearly in how well students in the two communities acquire English. The 'Swedes' (to use Ringbom's term) tend to do better on global measures of proficiency even though both groups have highly comparable socioeconomic and educational backgrounds and even though some 'Finns' are highly successful. The difference in performances is consonant with the fact that Swedish, a Germanic language rather similar to English, allows many more opportunities for positive transfer than does Finnish, a non-Indo-European language. Other research points to a similar advantage for the Swedes (e.g., Sjöholm 1995), and Jarvis (2000) has extended the methodology by looking at the performance of Swedes and Finns in their native languages in a film narration task: specific differences in their use of Swedish or Finnish show up in the English patterns of the two groups.

Not all language contact situations allow for the systematic comparisons seen in the Finnish research, but sometimes researchers can use the implications of such methods to make convincing arguments about cross-linguistic influence. The use of so-called *after* perfects in Ireland and Scotland offers one such example. Speakers of English in some parts of both regions often use *after* to mark temporal meanings involving 'hot news' and other notions: e.g., *I'm after forgetting all that lot now* (= *I have forgotten all that now*) (Sabban 1982: 155). Close translation equivalents can be found in both Irish and Scottish Gaelic, and the likelihood of transfer is all the greater because *after* perfects rarely if ever appear in learner varieties of English in places outside the Celtic lands. One can argue whether it was positive—as opposed to negative—transfer that led to the spread of *after* perfects in the days when English was still new in many parts of Ireland and Scotland (especially in the eighteenth and nineteenth centuries). In either case, however, the pattern illustrates a likely instance of cross-linguistic influence. It is not only in cases of explicit comparisons such as the difference between the English of Finns and of Swedes that allow for good inferences about transfer. Instances such as the *after* perfect constitute comparisons no less sound between contact in the Celtic lands and contact elsewhere, cases which may be called *implicit comparisons*.

3. Transferability

As the discussion in Sect. 2 indicates, the strong version of the methodological argument against substrate influence ('Transfer is impossible to determine') is not credible. The other two arguments in their strong form likewise fail empirically, though at the same time it must be said that researchers have not always found cross-linguistic influence in every case where it is imaginable. For instance, it is conceivable that Chinese learners of English might try to create a system of lexical tone in their interlanguage since their native language employs such a system. Such attempts, however, are either very rare or completely nonexistent in a fairly copious research literature about the difficulties encountered by Chinese learners. In such cases, it seems reasonable to posit constraints on language transfer. Yet although such constraints appear plausible in many cases, empirical work shows that learners actually ignore some supposed constraints and draw on their native language to try to make sense out of the target language.

One supposed constraint that has had longstanding appeal involves bound morphology. In its strongest form this constraint would have it that learners never rely on either the inflectional or

derivational system of their native language in acquiring grammatical categories in the target language. Somewhat weaker versions have focused on putative constraints involving inflectional systems. However, Jarvis and Odlin (2000) have discussed empirical work that refutes any strong claim about the nontransferability of inflectional morphemes. One study (Orr 1987) indicates a very different level of success of speakers of an Indo-European language (Gujarati) and speakers of a Bantu language (Ngoni) in learning the complex inflectional system of noun prefixation in Chichewa, another Bantu language—not too surprisingly, the speakers of Ngoni generally had an easier time with the target language prefixes in comparison with the speakers of Gujarati, a suffixing language. While the Orr study shows clear evidence of positive transfer, Jarvis and Odlin have identified unambiguous cases of negative transfer involving prepositional choices by Finnish learners of English, choices that show influences from the inflectional system of the Finns' native language. For example, in recounting events in a film several Finns described a scene where two people sit on a lawn with the predicate *sit to the grass*, which reflects an allative case suffix in Finnish. The likelihood of this interpretation is very high since a comparable group of learners whose native language was Swedish never used the predicate *sit to the grass*, and instead chose prepositional constructions compatible with those in Swedish. Moreover, a number of Finns writing in their native language used the allative case to describe the same referent in the same discourse context (i.e., *nurmikolle*, 'to the grass'). The studies by Orr and by Jarvis and Odlin thus indicate that either positive or negative transfer can occur in some situations even though there may be some rather specific constraints on the transferability of bound morphology.

Some work on the acquisition of syntax likewise shows strong evidence of native language influence. The domain of relativization has attracted several transfer researchers, and their investigations suggest that the variation in relative clause patterns of the first language can result in highly different interlanguage patterns of relativization. Work on the acquisition of English and of Swedish discussed by Odlin (1989) makes clear that pronoun retention is one possible outcome as when, for example, speakers of Persian might say in English, *I know the woman that John gave the potato to her*, which reflects the argument structure of Persian. A study by Mesthrie (1992) shows still other relativization strategies affecting interlanguage patterns. One involves word order reflecting the prenominal modification strategy favored in Dravidian languages as in the sentence *People (who got working-here-for-them) sons, like, for them nice they can stay* ('It is nice for people who have sons (who are) working for the company, since

they are allowed to stay on in the barracks'). In the case of some speakers of Indic languages, however, Mesthrie found a different relativization strategy involving correlated elements as in *But now, which-one principal came here, she's just cheeky like the other one*. ('The principal who arrived recently is just as stern as the previous one.') Yet another relativization strategy that can lead to varying interlanguage patterns is seen in the specific choice of a pronoun. In a recent study Odlin and Jarvis (2000) found that speakers of Finnish chose *what* in relative clauses normally calling for *who*, *whom*, or *that* as in *But same lady what he meet come to police car too*. A comparable group of native speakers of Swedish did not employ *what* in such cases. The evidence reviewed in this paragraph thus suggests that transferable relativization strategies include pronoun retention, constituent order, correlation, and pronoun choice. Not only do relative clauses appear to be highly transferable; each of these particular strategies seems a likely candidate for transfer in structural patterns not involving relativization. For example, Filppula (1999) has seen evidence for Irish influence in pronoun retention in the English vernacular of Ireland called Hiberno-English in structures other than relative clauses, and Keesing (1988) has shown likely transfer patterns of personal pronoun distinctions from Oceanic languages into Melanesian Pidgin.

4. Social Diffusion of Transfer Patterns

The cases of transfer involving bound morphology and relativization constitute an important part of the evidence refuting any strong claim about the psycholinguistic impossibility of transfer even in the controversial domains of morphology and syntax. However, not all the research cited so far has focused on cases where cross-linguistic influence has led to widespread social diffusion. Thus in the case of Finland, for example, the differences between Swedes and Finns in using English as a second (or third) language do not seem to have much of an effect on English more generally. Although English is indeed used as a lingua franca between Finns and Russians, for instance, there seems to be only a minimal impact of Swedish and Finnish on the structure of English as used in Europe (much less the rest of the world). If all cases of transfer had the limited social scope seen in the Finnish context, the strong sociolinguistic argument cited above ('Transfer will not alter the language of a speech community') might seem viable. However, evidence from contemporary and historical cases of language contact suggests that cross-linguistic influence can sometimes have a lasting impact on the diachrony of a language, the impact often being termed a *substrate*.

The clearest cases of substrate influence arise in situations where there are still bilinguals more proficient in one language than in another (see

Bilingualism and Language Acquisition). For example, Sabban (1982) found that older Gaelic/English bilinguals in the Scottish Hebrides showed more frequent retention of tense, modality, and aspect patterns influenced by Gaelic in comparison with younger bilinguals. Filppula (1999) similarly found differences in the frequency of cleft and absolute constructions parallel with ones in Irish, with these structures being especially common in regions of Ireland where bilingualism was until recently very widespread. Although some types of cleft and absolute constructions appear in most varieties of English, some occur almost exclusively in the Celtic lands, and as these structures have counterparts in Irish and Scottish Gaelic, they provide further support for Filppula's substrate analysis. For example, Odlin (1997) notes the co-occurrence of a reflexive pronoun and a cleft construction as in *It was himself that told me that up in a pub*, with such cases reflecting the common use of reflexive pronouns in cleft structures in Irish and Scottish Gaelic. One methodological problem that arises in the Celtic regions has also complicated the study of language contact elsewhere; a pattern said to be unique to a region can sometimes have its source in a nonstandard superstrate (target language) variety. However, the studies cited in this paragraph have taken such possible effects into account. As long as accurate information about nonstandard superstrates is available, it will sometimes be possible to determine the relative contribution of substrate and superstrate influence (cf. Odlin 1991).

Studies of pidgins and creoles have frequently invoked substrate influence as an explanation for the development of particular structures. Although such explanations have often proved highly controversial, some cases leave little doubt that there have arisen language transfer patterns in historical cases of language contact. For instance, the pronoun systems of many Oceanic languages have frequently grammaticalized dual and trial number as well as inclusive/exclusive distinctions. With the development of Pacific pidgins (see *Pidgins and Creoles: An Overview*) using mainly English vocabulary, pronoun systems quite different from the superstrate have emerged in various places such as the Solomon Islands (Keesing 1988), where duels are part of the pronoun system (e.g., the dual *iutufala*, literally you-two—fellows, 'you two,' in contrast to the plural *iufala*, literally you fellows, 'you'). This development is certainly not characteristic of all pidgins and creoles worldwide, nor is it characteristic of second language acquisition in other settings (even though one might imagine learners engaging in some kind of creative construction of new pronoun categories). This example from language contact in the Pacific conforms, then, to the methodological point made before of where researchers can sometimes use an implicit

comparison as strong evidence of cross-linguistic influence.

The cases of language contact in the Celtic lands and in the Pacific discussed in this section come from recent history. Not surprisingly, the farther back in time one goes the greater the uncertainties. For instance, the use of the auxiliary *do* in English may reflect an early Celtic substrate, one that presumably developed the wake of the conquest of much of Celtic Britain by the Anglo-Saxons. Poussa (1990) has made interesting arguments for just such a scenario, but inevitable problems make it unclear whether historians of Old and Middle English will concur on the substrate explanation in this case. Such difficulties arise from a lack of any bilingual speech samples from the time, as well as from uncertainties about just what shape the substrate pattern in Welsh and Cornish took, not to mention uncertainties in interpreting existing written evidence relevant to the problem.

In the case of the Old English period, there is at least some certainty about what languages were spoken in a contact situation, which no doubt existed. The linguistic evidence gets thinner in some cases where researchers in other fields seem reasonably sure about identifying distinct populations that would have been users of substrate and superstrate languages. For example, the archeologist J. P. Mallory (1999) argues that the simplification of the more highly inflected Ogam Irish to Old Irish reflects a language contact situation in Ireland existing some time between 2000 to 3000 years ago. In this interpretation, the superstrate language is a known variable, but not the substrate. Still more ambitious are the distinctions that some DNA researchers see between older and newer populations. Looking at the distribution of a Y-chromosome in Western Europe and the Middle East, a team of geneticists has argued that inhabitants in the West of Ireland share the chromosome most clearly with inhabitants of the Basque region of Spain, a commonality that may reflect a settlement pattern stretching back 4000 years (Hill et al. 2000). Although it is tempting to deem Basque the substrate language, there is no certainty on that point (or, of course, on what Basque might have been like four millennia ago). In the absence of linguistic methods hard to conceive of now, it will remain a hazardous venture to make strong claims about the language contact situations of prehistory.

5. Conclusion

This article has considered the strong form of arguments against the possibility of language transfer (a.k.a. substrate influence) and found all three of them (the methodological, the psycholinguistic, and the sociolinguistic) to be empirically unsound. Yet while the strong form of each argument is insupportable, it would be wrong to conclude that transfer

operates in every conceivable situation. Much empirical work remains to be done before researchers can specify the precise conditions under which transfer does or does not operate (see further Odlin 2002).

Lingua Franca

M. Barotchi

The term *lingua franca* (plural *lingue franche* or *lingua francas*) is used to refer to any form of language serving as a means of communication among speakers of different languages, for example, Swahili in East and Central Africa or English worldwide. The terms 'common language' and 'auxiliary language' are also used to refer to such a language.

1. Origin of the Term

The Italian term *lingua franca*, means literally 'French' or 'Frankish language,' apparently an adaptation of the Arabic phrase *lisan alfiranj*, 'language of Western/Latin-speaking Europeans,' (Zago 2000). It originally referred to a vernacular Romance tongue spoken along the Mediterranean coast between Marseils and Genoa, an early relative of modern Italian and Provençal. This was adopted as an auxiliary language among the Crusaders—who spoke different languages—and became mixed with Arabic, Greek, Spanish, and other elements. In time

this Crusader language became extinct but the name *lingua franca* survived as a general term of any comparable language. *Sabir* and *Petit Mauresque* are nineteenth-century versions of Lingua Franca used during the French colonization of Algeria and North Africa (Corré 2000).

2. Definition and Application

In the 1953 UNESCO Conference on Vernacular Languages, *lingua franca* was defined as 'a language which is used habitually by people whose mother tongues are different in order to facilitate communication between them' (UNESCO 1953). This definition applies also to pidgins and creoles, perhaps more to Creoles because of the requirement of habitualness (see *Pidgins and Creoles: An Overview*). Samarin 1968 points out that while all pidgins are lingua francas, not all lingua francas are pidgins. The term covers not only pidgins and creoles but other

503

natural languages and specially devised artificial auxiliary languages (see *Artificial Languages*).

3. Types of Lingua Franca

Samarin 1968 recognizes three types of lingua franca: 'natural,' 'pidginized,' and 'planned.' The 'Koiné' or Common Greek is one of the earliest known natural language lingua francas, spread as a result of the conquests of Alexander the Great, Greek colonization, and the dissemination of the Eastern (Orthodox) Christianity (see *Koinés*). Latin was another early lingua franca, associated with the rise of the Roman Empire and, for long after the fall of this Empire, with the Roman Catholic Church.

It could be argued that the 1953 UNESCO definition of a lingua franca quoted above makes it difficult to include pidgins as lingua francas in that pidgins are used only for restricted purposes and hence, it could be contended, are not used habitually. Since pidgins are quite clearly auxiliary languages used to facilitate communication between speakers of different languages, one might suggest that the word 'habitually' could be removed from the UNESCO definition.

The third type of lingua franca is artificial in the sense of being planned; languages such as Esperanto, Frater, and Interlingua fall into this category, being devised respectively by Ludovik Zamenhof, Pham

Xuan Thai, and a team of scholars belonging to the International Auxiliary Language Association. Though they are comparable to pidgins in possessing a mixed lexicon and a simplified syntax, they differ from them in being deliberately designed, sometimes indeed for specific uses, as is the case with Loglan, devised for use among certain scientists for restricted purposes.

Migrants and Migration

A. M. Pavlinić

1. The Origin of the 'Problem'

The Europe of the second half of the twentieth century has been characterized by multinational, plurilingual states, and cultural heterogeneity, with the exception of the linguistically homogeneous and monolingual Iceland and Portugal. The fusion of nations, cultures, and languages has been greatly accelerated by the migration of people coming from the underdeveloped and rural regions of Greece, Italy, Turkey, Spain, Portugal, the former Yugoslavia, North Africa, South and Southeast Asia, etc. in search of more lucrative employment or a better life in highly developed industrial and urban areas.

The migration situation during the economic boom of the early 1970s, before the oil crisis, could best be understood by applying the *Gastarbeiter* model of rotating migrant workers. It implied a temporary employment in the host country, and a return to the

home country as soon as the migrants' services were no longer necessary or when their material interests were satisfied. Castles, an expert in the political economy of migration, was among the first to use the 'subclass' denomination to describe the position of migrant workers being reduced to their working role. With their settlement on a more permanent basis, the ensuing process of so-called family reunification and of migrant family reproduction in the recession period, their developing new communities in most major European cities and industrial centers, and their gradual insertion in social and societal processes which do not stem solely from labor, it became more appropriate to refer to their position as 'ethnic minorities' (generally meaning newer minorities resulting from migration, as opposed to traditional ones). Suddenly, faced with the growing problems of migrants and their families, the countries of immigration became aware of the fact that, to paraphrase

Max Frisch, 'labor was invited, but there came people.' Consequently, immigrants' adaptation and integration (assimilation) became crucial issues in the richer communities of Europe in the 1970s, and have remained important, especially where 'second-' and 'third-generation' migrants are concerned, and in view of the global integration of Europe, which officially started in 1992.

It is well-known that a profound sense of attachment to their homeland is preserved by most migrant workers, sometimes also serving as some kind of protection in their new environment. However, they also develop strategies of integration with their adoptive setting in capitalist industrial society. But there is a social distance, very difficult to overcome, between the indigenous population and immigrant groups, even between foreign workers and native ones. A crisis such as an economic one (growing scarcity of primary goods available, particularly employment and housing, loss of purchasing power, reduced social welfare and funds for special purposes, including mother-tongue tuition) has an impact on relations between various sociocultural groups (in the form of growing nationalism, rising xenophobia, and the shutting in of immigrant and native communities on themselves). Class relations are underlined through social and economic segregation: internal and interclass conflicts are further deepened. The indigenous working class generally adheres to the country's sociopolitical system and immigration policies, which keep its members assured that the system of discrimination is necessary so that their own interests, seemingly threatened by the presence of foreign workers, can be protected. The political integration of foreigners is not even at issue, unlike their sociocultural integration, because no such sociocultural–political order has been created in which they would have a say. By 1990 only three European host countries had granted immigrants the right to participate in (municipal only) elections: Belgium, Sweden, and the Netherlands.

1.1 How to Define a Migrant?

The term 'migrant,' pregnant with connotations, changes according to whether it is viewed from a legal, economic, sociological, anthropological, psychological, pragmatic, or political point of view, especially if the term is used to refer to the children of migrants (or former migrants). A most comprehensive and acceptable definition can be found in the Council of Europe's *Project No. 7* (1986):

— when defined **BY HIS PAST**, a migrant is *someone uprooted from his homeland*, from his community and his 'rural society,' through 'economic violence' (lack of means of livelihood) or 'political violence' (refugees): this context has a profound effect on his present and his plans for the future, and it is one with which he maintains a relationship; as *someone with a given nationality*, he is perceived as different by the society of the country of residence (which is associated with historical, economic, political, cultural factors); the differential treatment and perception of identity strengthen his tendency to identify with his ethnic group (ethnic cohesion); as a *carrier of linguistic and cultural codes*, his daily behavior is governed by this fact; coding may relate to time, space, cooking, clothes, religious practices, etc., revealing a number of cultural factors that are 'universal';

— when defined **BY HIS PRESENT**, he is a *settler* ('resettler'), who has resided in a given country, sharing the problems and interests of the local community; he has civic communication needs and social communication needs (system of predominantly accepted norms and values); as a *worker*, he has a specific role to play within the national production system and within the framework of the international distribution of labor; he lives on new class loyalties shared with indigenous workers; as a *non-citizen*, he has no political rights and a precarious residence status; he is, sometimes, a *member of a minority* (where his group often has negative connotations in relation to the society of residence); 'immigrant minorities' are to be distinguished from all other minorities on account of their origin, history and present positon; as a *deprived person*, he lacks means of communication, particularly linguistic means, he belongs to a disadvantaged social category (lack of schooling and vocational training), and is liable to social discrimination;

— if defined **BY HIS FUTURE**, he is a 'mutant' or *cultural traveler* caught in a 'transit' situation (being forced to change his 'cultural spectacles' on account of his new social itinerary); as an *agent of social and cultural change*, he is engaged in a process of reaction to a new setting which is itself influenced by his presence; the 'transplanted' immigrant changes in and with settings which themselves change; as a *progenitor*, he is a producer of new generations marked by his economic, social and cultural experience; he tries to pass on his language of origin, his models of behavior and values; he projects on his offspring his own aspirations, but he also transfers his own frustrations to them; as a *child of immigration*, not only does he undergo the socialization and cultural influence of his family, but he is increasingly marked by the new socializing and educational influences outside the family (school, district, recreations, media, peer groups, etc.), refusing to confine himself to the cultural profile of his parents. This is how migrant workers' offspring, especially 'second-generation' (most often, but not invariably defined as those who were born in the country of emigration and came to the receiving country to join their parents, complete their education, and eventually find employment there themselves), even 'third-generation' migrants (those who were born in the country of immigration) are most frequently referred

505

to: as *carriers of bipolarity*, their sociocultural integration in the host community being limited by influences and feelings pertaining to the country of origin, and, vice versa, their acceptance of sociocultural patterns, structures and values pertaining to the adoptive country meaning their 'sacrificing' their indigenous characteristics, originality and self-reliance.

It is clear who is the controller, and who the controlled in the world of immigration.

2. Factors Affecting the Integration of Migrant Workers' Children

According to some estimates, there were probably 20 million migrant workers in the world at the beginning of the 1980s. It has also been estimated that in the year 2000, one-third of the population under the age of 35 in highly developed Europe is of immigrant background. The young foreign population can therefore be considered as the new Europeans, carrying the variety of different cultural expressions emerging from their own national or regional cultures. It is a tremendous challenge for those in control of cultural and educational policies to recognize this potential, and provide the opportunity whereby they can be made an asset for European unity, understanding, and progress.

While migrant parents have been the target of selective integration (the able-bodied, skilled, very healthy, communicative, and ambitious are favored), their children lend themselves more easily to full integration (assimilation, 'cultural homogenization'), for both objective and subjective reasons, especially if the process started at the earliest age, from birth.

Migrant children permanently undergo and deal, more or less successfully, with the conflicting impact of factors related to their education, personality development, and culture: the home and family on the one hand, and the school as a purveyor of knowledge, cultural heritage, achievements, value orientations, norms of behavior, relating to the majority society on the other. It is probable that 'third-generation' migrants will find it easier to cope; 'second-generation' migrants are in a specially vulnerable position, because they were first socialized in a different sociocultural milieu, by means of a different language, and the switch may have left permanent scars on their psychosocial life.

The school success of young foreigners is, naturally, crucial to their sociocultural integration and for their future standing in the labor market (economic integration). Their majority language (L2) competence is the most important instrument for achieving a good school career as well as a key opening the door to a successful integration. In an early article on migrant children's language problems, Trim remarked:

> A language course which aims at a generalised competence and has no social context is likely to prove ineffective....
> We should in our teaching try to analyse a hierarchy of social problems, and then look for the language which will *enable the young migrant to assert his social rights within the problem areas*, developing his ability to do so in an order of priority which results from the magnitude of the problem, taking into account both long and short term aims.
>
> (Trim 1977: 217–8)

The earliest objective of keeping the language (LI) and culture of origin alive in the host countries was encouraged by the hope of the (re)integration of migrant children in the school should they return to their home country. Although an important conclusion has been reached in recent years, namely, that a pupil's knowledge of his origin enhances his (her) ability to integrate in either of the two (or more) societies, a top-down focus of the host country's power structures and majority language teachers has remained on L2 acquisition, often combined with a rather negative attitude toward maintaining L1. Indeed, stress is sometimes put on preserving (ethnic) culture rather than the language, as if one could exist free from the other. There is a matching bottom-up focus of dominated groups (including minority language teachers) and of the countries of their origin on mother tongue and ethnic culture maintenance, for the purposes of bridging a gap between the parents and the children, building and preserving ethnic identity, and acquiring L2 more successfully (see Sect. 3). A consensus of opinion about the weight of the two languages in the school curriculum has not been reached yet despite a long debate and despite contrary claims on the policy level.

In addition to the migrant home and the host country's school as the two crucial sources of the children's culture, there are also other influences to be taken into account in view of their integration in the dominant society. An important factor is the institutions (including migrant associations, mass media) that encourage the cultures of the country of origin or of the adoptive country. (There is usually a lack of such institutions, or a lack of 'official support for cultural and language maintenance,' as it is generally called.) The importance of the peer group also deserves to be stressed in this context, especially when socialization in childhood, as well as in adolescence, is concerned. Last but not least, one internal factor should not be overlooked: *Selbst-Aktivität* (to use the German term meaning 'self-activity') is known to have performed miracles in individual instances. It may be defined as a person's strategies to make the best of his (her) heredity- and

society-related dispositions, although either or both can be adverse, in direct or in indirect consequence of migration.

2.1 The Political Lever in Operation

It has been argued so far that migrant children's problems should be viewed as a consequence of migration-related phenomena (in addition to their possibly being, as far as some aspects are concerned, children's universal problems), that their causes should be sought in the community of origin and/or the receiving community, and that the linguistic aspects of their school achievement problems cannot be separated from the economic, cultural, and political aspects of their situation. This last factor deserves to be dealt with by itself, because it is unavoidable in the past, present, and future of migrants' lives.

It may be called the *political lever*, a concept which includes immigration and emigration policies alike, educational and language policies, and language planning. Examples of the political lever in operation are numerous. Compared with other European policies, the UK was early in adopting a new terminology, substituting the word 'minorities' for 'migrants' in the early 1970s. Among other things, such a change enables the host society to distinguish itself in a new way from the new cultural and linguistic groups; also, it makes a reception and integration policy possible which does not depend on the assumption of a return home or departure, as is often the case elsewhere in Europe; it also gives the white population a particular identity enabling it to call itself the 'majority' (Bottani 1989: 39). The European Community ensures for its members greater mobility within and between its more developed countries, better employment conditions, more flexible school conditions for the pupils, etc., which leaves the non-EC members outside, void of comparable provision. The Elementary Education Act in the Netherlands (1985) has reduced the number of classes per week spent on language and culture of origin instruction (in Dutch, OETC or 'onderwijs eigen taal en culture'), and made such tuition obligatory for pupils only at the request of their parents. Churchill (1987: 67) has made an interesting general remark concerning what he calls 'strong political interventions': that the response of the educational system to problems presented by the education of linguistic and cultural minorities is always confined within the bounds of what is tolerable for dominant (majority) opinion; stepping beyond these limits usually results in strong political interventions that can override what educational policy makers have done. Churchill also reports (1987: 80), however, a positive development in the OECD countries: most of their jurisdictions have eliminated negative stereotyping of different cultures and ethnic groups from their school textbooks and their official educational culture; also,

the right or need of the minority to learn about its own history and customs is recognized, so the teaching of 'culturally relevant' topics such as social studies, history and geography, may occur in the minority language.

One of the very few books dealing with the question of power in language and the language of power is J. Mey's *Whose Language? A Study in Linguistic Pragmatics* (1985). This very question is implied in its title: 'whose language' do people speak, the language of the colonizer, or that of the colonized? The author's point of departure is his acute awareness of the fact that the powerful in society, as well as the less powerful and the powerless, all depend on the socioeconomic conditions in that society. Consequently, he believes that for a socially oriented theory of language use a detailed analysis of such conditions is absolutely necessary. The book is also an answer to the question that has been the author's preoccupation for a long time concerning the role of science in society and, more specifically, the role of linguists and linguistics. It is both a political statement and a contribution to science. (Some politicized issues pertaining to migrants' mother tongues can also be found in Dabène et al. 1983.)

3. A Brief Overview of Minority-related Linguistic Issues and Some Selected Literature

With immigrants and their families establishing themselves in the receiving societies came the realization that the speech communities had acquired a new repertoire of *varieties*, whether registers, dialects, diatypes, or languages (see *Language*; *Dialect and Dialectology*; *Register*). Labov defined a speech community as a group of speakers who share a set of social attitudes towards language. It has been supported by sociolinguistic theory and successfully proven by the same author that some of the elements that set off variation, i.e., the choice of alternative linguistic forms and switching (see *Code-switching: Overview*) between varieties in general, come from conditions external to the speaker and others from internal states (for studies of this nature see also articles in Pride and Holmes 1972). 'Communicative competence' is an important step on an abstract, theoretical level, in the development of sociolinguistics as a science, and on a concrete level, as a contribution to the study of the language problems of disadvantaged children (see Hymes in Pride and Holmes 1972). It indicates some major dimensions: the capacities of persons, the organization of verbal means for socially defined purposes, and the sensitivity of rules to situations. (See *Language in Society: Overview*.)

The concept of 'diglossia' has been taken to refer to any two languages in contact as well as to cases where two or more varieties of the same language are

507

used in different social settings (see Grosjean 1982: 131–2). As diglossia concerns the social allocation of functions to different languages or varieties, it can be applied to immigrants' communication, with a distribution of functions between their mother tongue/diaspora language (See also *Minority Languages*; Grosjean 1982: 179 ff.).

In the diaspora context, the acquisition and use of the dominant language (L2) is in the focus of interest of migrants; if theirs is a minimalistic approach, they want to maintain their mother tongue at least to keep up language-links with the country of origin. Psycho- and sociolinguistic research on ethnic minority groups is also oriented towards the second language. Far less attention is given (for various reasons) to the dominant language (L1), although it is recognized at least as the expression of a person's primary identity and the language through which initial concept formation takes places (cf. Pattanayak 1986: 7). With various issues in the debate on inter- and multicultural education being increasingly accompanied by contradictions, hesitation, uncertainty, and backtracking (cf. Bottani 1989), and within a more global minority language revival trend in Europe, the 'mother tongue' concept has been receiving growing attention (see Denison et al. 1986, Ringbom 1987).

Bilingualism (see *Bilingualism, Individual*) is a characterization of individual and societal linguistic versatility; a bilingual person has skills (within the range from minimal to maximal) in two languages. Bilingualism in the context of migrants in present-day Europe is the subject of an edited collection by Extra and Verhoeven (1999). Skutnabb-Kangas (1984) (with a comprehensive bibliography) is an important work, especially on bilingualism relating to the education of minority children; for minority education issues see Skutnabb-Kangas and Cummins 1988 (See also *Cummins, Jim*).

If active, balanced bilingualism, that is (at least theoretically) as 'complete' a bilingualism as possible, can be discerned at one end of the continuum, (double) semilingualism—insufficient competence in both languages—might be seen at the other end (see Skutnabb-Kangas and Toukomaa 1976, Wande et al. 1987; see also *Semilingualism*).

The three most important linguistic contributions to the (gradual) establishment and promotion of bilingual education in multicultural, plurilingual settings seem to be:

  (a) the claim that all languages are the same in value;
  (b) research findings about the positive (cognitive) effects of bilingualism (see e.g., Baker 1988);
  (c) Skutnabb-Kangas's research findings (1976 onward), together with Cummins's interdependence hypothesis.

At the core of the hypothesis is a distinction between CALP (cognitive/academic language proficiency) and BICS (basic interpersonal communicative skills); Cummins claims that both L1 CALP (L1 competence and performance) and L2 CALP are manifestations of the same underlying dimension. Both Skutnabb-Kangas and Cummins are keen proponents of mother tongue medium maintenance education for minorities (L1 as the main medium of education, at least during the first six years of schooling, if not longer, with the major language as a second language).

4. The Definition of Language in Migrant Situations

When all considerations concerning the situation of migrant workers and their children are taken into account, a definition of language may be proposed:

  (a) from the majority perspective;
  (b) from the minority perspective; first, as the tool for controlling society in a field of tension between 'me/us' and 'you/them' is language; second, as the tool for becoming adapted to the controlling society in a field of tension between 'me/us' and 'you/them' and for making the best of the adoptive world is language.

5. Efficient Multicultural Education Program: A Desirable and (In)accessible Goal?

Mackey (see Grosjean 1982) was among the pioneers to propose a complex typology of educational programs, ranging from monolingual education in the majority language through bilingual education in both languages to monolingual education in the majority language (for programs that lead to linguistic and cultural assimilation and those that lead to linguistic and cultural diversification see Grosjean 1982: 208–22). Despite later work by other scholars, really efficient multicultural education programs and policies have not yet been drawn up. There is the mass of evidence pertaining to inter-/ multicultural (education) experience, but on the implementation level, still much to be desired. The main obstacle to more efficient bilingual education programs seems to be the notion of 'one language–one culture' still imbedded in the educational systems of former nation states in Europe.

Research in some Scandinavian countries and elsewhere has been directed at language transfer, interlanguage syntax, and similar issues (cf. Færch 1983, Færch and Kasper 1987, Hyltenstam 1987, Ringbom 1987).

An approach with more pragmatic goals, in that it is aimed at improving minority students' school careers, is that of Cummins (1990); his point of departure is that minority students are educationally

508

disempowered in very much the same way that their communities are disempowered by interactions with societal institutions. In other words, minority students are 'empowered' or 'disabled' as a direct result of their interactions with educators in the schools, and the 'problem' cannot be located within themselves. These interactions are mediated by the implicit or explicit role definitions that educators assume in relation to four institutional characteristics of schools. These characteristics reflect the extent to which: (a) minority students' language and culture are incorporated into the school program; (b) minority community participation is encouraged as an integral component of children's education; (c) the pedagogy promotes intrinsic motivation on the part of students to use language actively in order to generate their own knowledge; and (d) professionals involved in assessment become advocates for minority students by focusing primarily on the ways in which student's academic difficulty is a function of interactions within the school context. Each dimension can be analyzed along a continuum: one end reflects an intercultural orientation (role definition); the other reflects the traditional dominant-group-superiority orientation (cf. Cummins 1990: 165). The former serves the purpose of empowering students; the latter contributes to disabling them.

Missionaries and Language

P. Lewis

Missionaries of all religions have long had a strategic interest in language. As pioneer communicators of the message of their faith, missionaries have inevitably confronted linguistic barriers and have sought ways to deal with them. Missionaries have a very practical motivation to engage in the study of

language: linguistics, language acquisition, applied linguistics (translation, literacy), and sociolinguistics, and they have been at the forefront of linguistic data gathering, analysis, and application. Missionaries have also contributed to the development of linguistic theory, primarily as a foundation for achieving their practical ends.

1. Religious Ideology and Approaches to Language

Although missionaries are universally concerned with language and with the communication of their message, not all religions have approached language from the same perspective. Differing theological perspectives on the nature of deity and the relationship of that deity to the world result in different communicative strategies and religious language policies.

Judaism is nonproselytizing in nature and is closely associated with a biological and ethnic membership in the group. Converts to Judaism are generally expected to learn some Hebrew, the language of the Bible and of worship, but translations of the Hebrew writings are freely available and readily used.

In contrast, Islam holds that the only valid linguistic medium for divine revelation is the Koran in the original Classical Arabic. Translation of the Koran is therefore not a high priority. Instead, the general approach of Islamic missionizing has been through mass conversion and the arabicization of entire populations, at least in the religious domains of language use.

Hinduism, while not overtly proselytizing ideologically, has had at least segments of its practitioners who have undertaken the translation of the Hindu sacred writings and other religious materials for the purpose of making the teachings of Hinduism more widely accessible. As a prime, and perhaps extreme, example of this missionary spirit is Swami Vivekananda (1863–1902), a disciple of Ramakrishna, founded in India the Ramakrishna Mission or Vedanta Society. It was devoted particularly to philanthropic activities but also to the idea of a worldwide religion founded on a *Vedanta* adapted to the needs of modern societies. Vivekananda traveled extensively in the West expounding his views and has been called the 'St. Paul of the movement' (Pitt 1955: 46–7). Another Hindu missionary movement, the Arya Samaj, had as its slogan 'back to the *Vedas*' and linked Indian identity closely to adherence to Hinduism, resulting in a program aimed at converting Muslims and Christians in India to Hinduism. The linguistic consequences of such missionizing have been the propagation of Hindu sacred writings in the vernacular languages, while at the same time maintaining the Sanskritic tradition among the more educated.

Consideration of missionary activity is most often focused on Christianity, with its large corps of missionary personnel (over 400,000 worldwide by some estimates). The Christian theology of mission is founded firmly on the 'Great Commission' spoken by Jesus which commands Christians to 'go into all the world and make disciples.' It is also rooted in an ideology that the Christian Scriptures (the Bible) are the basis for faith and godliness and therefore must be adequately and accurately understood.

From its earliest days Christianity has been characterized by a drive to translate the Bible as a means of providing a basis for the preservation of orthodoxy and an accurate recounting of the life and teachings of Jesus. In practice, Christian missionaries generally see the need to lay the groundwork for the reception and use of the translated Scriptures as well. Thus, a range of applied linguistics activities frequently accompanies Bible translation. In cases where a language is unwritten, missionaries would consider it appropriate to develop an adequate orthography (e.g., Cyril, Methodius, Stefan of Perm). Where there are no readers, missionaries would consider it important to facilitate access to the Bible through literacy instruction and the production of other reading materials. Often missionary linguists also provide phonological, morphological, syntactic, and semantic descriptions of languages, and may also produce pedagogical grammars, dictionaries, and other linguistic materials. Linguists and scholars have benefited greatly from the linguistic, anthropological, and sociolinguistic data that missionaries have collected in thousands of languages in all parts of the world.

2. Missionaries and Language Identification

Because of the Christian mandate to go into all the world, Christian missionary linguists are preoccupied with the identification of the world's languages. Scholars, missionary and non-missionary alike, have made attempts to begin inventories of the languages of the world and to track the progress of Bible translation. The *Ethnologue* (Grimes 2000) is one of the most comprehensive catalogs of the languages of the world and relies heavily on field research done by missionary linguists and others.

The work done by missionaries in identifying the languages of the world has contributed to the development of the notions of language and dialect, inherent intelligibility, the role of language attitudes in intelligibility and language identification, and ethnolinguistic vitality (see *Ethnolinguistic Vitality*). In addition, missionary linguists have been pioneers in the development of techniques for the investigation of dialect intelligibility, language proficiency assessment (particularly in the less commonly used languages), and the investigation of language attitudes and use. Current work in language identification includes

research in pidgins and creoles, signed languages, and other nonstandard varieties used widely alongside national or regional standard languages.

3. Missionaries and Bible Translation

The list of Bible translators is long and colorful. As Christianity spread across, and then outside of the Roman empire, the Bible was translated into more and more languages. The earliest translations were the Aramaic and Syriac versions. The Vulgate translated (into Latin) by St. Jerome (340–420) was commissioned by Pope Saint Damasas I and completed in 405 CE. Ulfilas (311–382) devised an alphabet and translated the Bible into the Gothic language. He omitted the Old Testament books of the Kings, however, feeling that they were 'too bellicose to be edifying for a people already extremely fierce and warlike' (Shelley 1982: 173–4).

One notable example of a missionary as a linguist from the eighteenth and nineteenth century is William Carey (1761–1834), who set sail from England for India in 1793 and, though untutored, became a specialist in Oriental languages, particularly Sanskrit, Marathi, and Bengali. By the time of his death he had, with assistance from his colleagues, translated the Bible into 44 languages of South Asia and also had produced dictionaries and grammars in many of those languages.

At the forefront of modern Bible translators are two large interdenominational organizations, the United Bible Societies (a consortium of national Bible distribution and promotion agencies) and Wycliffe Bible Translators International (comprised of national and regional organizations around the world). They are joined by a number of smaller organizations, which are generally associated with a specific church body or denomination. Wycliffe Bible Translators works closely with SIL International, a Christian language development organization, which engages in linguistic research, literacy work, and translation.

Missionaries have contributed significantly not only to the production of Bible translations in numerous languages of the world, but also to the development of translation theory and practice. Nida (1947) (see *Nida, Eugene Albert*), Beekman and Callow (1974), Larson (1984), and others have developed practical translation methodology based on linguistic and sociolinguistic models of language and communication.

4. Missionaries and Applied Linguistics

Missionaries are motivated to engage in applied linguistics as a means of facilitating access to the Bible and other religious materials. They have been contributors to both theory and practice in applied areas such as language learning, orthography design, literacy instruction and instructional materials, writer

training, translation theory, bilingual education, and language development in general.

5. Missionaries and Sociolinguistics

Missionaries have had a small but important role in the development of sociolinguistics as a separate area of academic specialization. Early on, missionaries were aware of the important role that nonlinguistic factors played in the communicative process and recognized that language is very much situated in, and part of, culture. They have had a healthy respect for the importance of ethnographic aspects of language, although anthropologists and ethnographers have not always reciprocated that respect towards missionary anthropologists and linguists.

Kenneth L. Pike (1912–2000), early in his training as a linguist, recognized the importance of an holistic approach to language and culture and developed tagmemics, a theoretical model for linguistics, based on the recognition of three universal structural features: contrast, variation, and distribution. As Pike attempted to apply this approach to larger and larger units (first phonological and grammatical units, then entire languages) he realized that 'The English language was distributed into culture and was a part of culture' (Pike 1997: 211). This work led to his *Language in Relation to a Unified Theory of the Structure of Human Behavior* (Pike 1954) which is a summation of how language and society relate to and affect each other. A decade before sociolinguistics as such, was formally constituted – 1964 is the year of the birth of sociolinguistics in the United States according to most sources, (cf. Paulston and Tucker 1997)—Pike was struggling with variation and recognizing that the conditioning environment for much of the variation that linguists noted had to be social rather than linguistic. That concept would not be widely accepted and written about for another decade.

Eugene A. Nida of the United Bible Societies also wrote extensively on the sociolinguistic aspects of translation and the role that social structures play in communication.

The majority of missionary investigators who are writing in sociolinguistics are producing sociolinguistic descriptions of language communities, which include in-depth analyses from the perspectives of the sociology of language and linguistic anthropology. So far, missionaries have not done much work in microsociolinguistics, particularly in the area of variation analysis.

Several missionary sociolinguists are making substantial contributions to the development and application of Relevance Theory (Blass 1990, Gutt 1991). Semantics, pragmatics, discourse analysis (cf. Longacre 1983) and social network theory (see *Social Networks*) are also of considerable interest to the missionary community, since they have direct application to translation.

511

6. Missionaries and Endangered Languages

Perhaps the most controversial topic regarding missionaries in the last several decades has been language endangerment and the role that missionaries have had in regard to the status of endangered language groups. Critics accuse Christian missionaries of fomenting language and culture loss through their introduction of a message, which is culture changing and often associated with Western values and worldview.

Many missionaries, on the other hand, see themselves as champions of the use of the vernacular languages and argue that their interventions in communities where the language and culture is already endangered because of increasing contacts with outsiders often slows the pace of language shift, promotes a sense of self-esteem, and in some few cases has even preserved the use of a dying language. They argue that the introduction of literacy equips preliterate peoples to defend themselves in the encroaching literate world. In addition, missionary linguists, working with the last few elderly speakers of a language have preserved knowledge of those now-extinct languages. That knowledge is valuable both to the academic world and to the descendants of those speakers.

Native Speaker

A. Davies

1. The Native Speaker: Myth or Fact

The native speaker, like Lewis Carroll's snark, is a useful and enduring linguistic myth; again, like the snark, itself a product of the debate over idealism in philosophy, it must be taken with a large pinch of salt. Linguists may have

given a special place to the native speaker as 'the only true and reliable source of languages data' (Ferguson 1983: vii), but there is little detailed discussion of the concept, which is often appealed to but difficult to track down. Full-length treatments of the topic (Coulmas 1981, Davies 1991, Paikeday 1985) have yet to attract much comment. Ferguson's argument has to do with language use rather than with language knowledge:

> much of world's verbal communication takes place by means of languages which are not the users' mother tongue but their second, third or nth language, acquired one way or another and used when appropriate. This kind of languages use merits the attention of linguists as much as do the more traditional objects of their research.
>
> (Ferguson 1983: vii)

It is possible to agree with Ferguson's desire that linguistics pay more attention to language use without agreeing with his dismissal of the native speaker: 'In fact the whole mystique of native speaker and mother tongue should preferably be quietly dropped from the linguist's set of professional myths about language.'

2. Theoretical Issues

Theoretically, the 'native speaker' concept is rich in ambiguity. It raises, quite centrally, the issue of the relation between the particular and the universal. Chomsky, as a protagonist of the universalist position, conveys to Paikeday's questioning approach about the status of the native speaker (Paikeday 1985) the strongest possible sense of the genetic determinants of speech acquisition, which, as he sees it, means that to be human is to be a native speaker.

Chomsky equates language development with other normal development, finding no interest in questions about developmental states or stages, which he regards as contingent. In the same vein, Chomsky finds distinctions between synchronic states of language or languages and dialects uninteresting: 'the question of what are the "languages" or "dialects" attained and what is the difference between "native" and "non-native" is just pointless' (Chomsky quoted in Paikeday 1985: 57). Chomsky's whole argument depends on a rationalist opposition to 'incorrect metaphysical assumptions, in particular the assumption that among the things in the world there are languages or dialects, and the individuals come to acquire them' (Paikeday 1985: 49). And so Chomsky must conclude that 'everyone is a native speaker of the particular language states that the person has "grown" in his/her mind/brain. In the real world, that is all there is to say' (1985: 58). This is a major thread in the range of views on the native

speaker, and will recur later. Chomsky's view is uninfluenced by any social factor or contextual constraint. Variety and context, he seems to argue, are trivial. This is a thoroughgoing 'unitary competence' view of language in which language use is contingent and the native speaker is only a realization of that competence at linguistic and not at language level. For Chomsky, like many theoretical linguists, is not interested in languages: what he studies is language.

3. Educational Issues

Halliday (see *Halliday, Michael Alexander Kirkwood*) appears not to use the term 'native speaker'; however, what he says about the mother tongue is very relevant. He comments:

> Opinions differ regarding the uniqueness of the mother tongue ... for very many people ... no language ever completely replaces the mother tongue. Certain kinds of ability seem to be particularly difficult to acquire in a second language. Among these, the following are perhaps most important in an educational context:
> (a) saying the same thing in different ways,
> (b) hesitating, and saying nothing very much...
> (c) predicting what the other person is going to say...
> (d) adding new verbal skills (learning new words and new meanings) when talking and listening.
> It is not being suggested that we can never learn to do these things in a second language ... Nevertheless, there are vast numbers of children being educated through the medium of a second language, and of teachers trying to teach them, who have not mastered these essential abilities.
>
> (Halliday 1978: 199–200)

To what extent educational disadvantage can be attributed to not being a native speaker is debatable, especially since a similar argument of lacking adequate language resources is made for certain groups of native speakers who, it has been claimed (Bereiter and Engelmann 1966), suffer from a language deficit (see *Code, Sociolinguistic*). The basic question here is which code (whether language or dialect) one is supposed to be a native speaker of.

A contrary view to Halliday's is given by the American linguist, Leonard Bloomfield, author of *Language* (1933) and student of Native American languages in the anthropological tradition of early twentieth-century American linguistics. Like Halliday, Bloomfield does not use the term 'native speaker' but writes instead of 'the native language':

> The child growing up in the province, say, in some mountain village, learns to speak in the local dialect. In time, to be sure, this local dialect will take in more and more forms from the standard languages ... The child, then, does not speak the standard language as his native

513

tongue. It is only after he reaches school, long after his speech-habits are formed, that he is taught the standard language. No language is like the native language that one learned at one's mother's knee: no-one is ever perfectly sure in a language afterwards acquired. 'Mistakes' in language are simply dialect forms carried into the standard language.

(Bloomfield 1970: 151)

In another context, Bloomfield does refer to the native speaker: 'The first language a human being learns to speak is his native language; he is a native speaker of this language' (1933: 43). Bloomfield makes the obvious point that children learn to speak as they learn to do everything else, by observation, participation, and interaction with the people around them.

4. Psycholinguistic Issues

Katz and Fodor, more concerned with the relation between language and the mind, argue that 'The goal of a theory of a particular language must be the explication of the abilities and skills involved in the linguistic performance of a fluent native speaker' (1962: 218). In this way, the native speaker becomes central to the interests and concerns of linguistics, with the native speaker being the relevant example of natural phenomena for scientific study. Chomsky refers to the native speaker as being both the arbiter of a grammar and (when idealized) the model for the grammar: 'A grammar,' he says, 'is ... descriptively adequate to the extent that it correctly describes the intrinsic competence of the idealized native speaker' (1965: 24).

Chomsky thereby neatly compounds one of the central ambiguities of the 'native speaker' idea, using it to refer to both a person and an ideal. Or, as Coulmas says, 'The native speaker leads a double life in Chomsky's work, (a) as a creature of flesh and blood, that is the linguist himself, (b) an idealization' (Coulmas 1981: 10). Richards et al. in their *Dictionary of Applied Linguistics* (1985) and Crystal in his *First Dictionary of Linguistics and Phonetics* (1980) emphasize the importance of intuition in defining the native speaker, Crystal helpfully pointing to the need to take account of bilinguals who are native speakers of more than one language.

5. The New Englishes

Tay's contribution to the discussion is original in that she comments on the status of the native speaker in relation to the so-called New Englishes (see *New Englishes*), that is, the English of Singapore, India, and so on. She refers to the lack of clarity of most definitions, and notes that the two factors usually appealed to are priority of learning and an unbroken oral tradition. She comments that both are unsafe

criteria; the first because of bilingualism, the second because an adult may have shifted dominance from one first language to another or because a second learned language may have had as much influence on a first learned as the other way around. Tay therefore proposes that a native speaker of English who is not from one of the traditionally native-speaking countries (e.g., the USA or the UK) is:

one who learns English in childhood and continues to use it as his dominant language and has reached a certain level of fluency. All three conditions are important. If a person learns English late in life, he is unlikely to attain native fluency in it; if he learns it as a child, but does not use it as his dominant language in adult life, his native fluency in the language is also questionable; if he is fluent in the language, he is more likely one who has learned it as a child (not necessarily before the age of formal education but soon after that) and has continued to use it as his dominant language.

(Tay 1982: 67–8)

These views indicate the accuracy of Coulmas's statement that a tension exists between the flesh and blood and the idealization definitions.

6. Practical Issues

The practical importance of the term is emphasized by Paikeday (1985), pointing to the employment discrimination against those who lack the 'ideal' native speaker attributes: 'native speakership should not be used as a criterion for excluding certain categories of people from language teaching, dictionary editing, and similar functions' (1985: 88).

Paikeday's own solution seems to be to separate the ideal and the operative meanings of native speaker, making proficiency the criterion for employment, and personal history the criterion for ideal membership. Such a rigid distinction is difficult to maintain when it comes to judgments of grammaticality which Paikeday wants to associate with the 'proficient user' meaning of 'native speaker' rather than with the 'ideal member' use: 'the people we refer to as arbiters of grammaticality are not really so because true arbiters of grammaticality are proficient users of languages, not just native speakers' (1985: 53).

The challenge which Paikeday sets is essentially which native speaker to choose, and lurking behind all such choices is undoubtedly his dilemma of whether a new model (which can be supported by acknowledged proficiency) outweighs a distant 'historically authentic' model; for example, Indian-English models or Nigerian-English models versus British or American models. However, this dilemma is just one example of the more general case. There is a dispute between the British and American models just as there is among other metropolitan models,

and just also as there is between any Standard and other dialects. The important choice of a model therefore raises issues of acceptability, of currency, and of intelligibility. It is in part for this reason, that Paikeday's distinction between the 'ideal' native speaker definition and the 'operative' one is not finally tenable.

Nevertheless, the distinction is of practical importance in the institutionalized activities of publishing and examining, in the written language, and of selecting radio and television newsreaders in the spoken. There has generally been consensus in favor of a model type being used. It is also usual for a particular type of native speaker (or native-speaker-like non-native speaker) to be chosen—the prestige model. However, the prestige model has been rejected by some influential groups. In 1991, the large, international organization, Teachers of English to Speakers of Other Languages (TESOL), issued a statement (Forhan 1992) condemning any action which 'supports the exclusion of individuals who are nonnative speakers of English from employment opportunities within the profession.'

The term 'native speaker' is used in two distinct (but related) senses in relation to the prevailing consensus. The first is that in some way the native speaker is taken to represent an idealized model. The second is that an individual native speaker is him/herself used as an exemplar of such a model.

In academic settings, requests for native speakers to come forward (to take tests, to act as informants) may cause offense. First, what is not stated is that what is typically being referred to (in the UK or USA) is being a native speaker of English; second, it is ignored that everyone is a native speaker of some code; and third, it is denied that a highly proficient nonnative speaker may also have acquired both linguistic and communicative competence and be, therefore, in terms of what is required in formal higher education, indistinguishable from a native speaker.

7. Racism

What is also ignored is the racism of such remarks; what is so often meant by native speaker in the above context is the deliberate exclusion of those who are in with a chance. A Singaporean, a Nigerian, or an Indian might see him/her as a native speaker of English but feel a lack of confidence in his/her 'native speakerness.' The counterargument is that, in all such cases, it is really up to the individual to identify him/herself; no one else can do it. Where there is doubt, people define themselves as native speakers or as nonnative speakers of particular languages. As far as English is concerned, the problem is peculiarly one for those who belong to the postcolonial communities, such as Singapore, Nigeria, or India, where the

New Englishes are in use. Membership as native speakers is largely a matter of self-ascription, not of something being given; it is in this sense that members decide for themselves. However, those who claim native-speaker status do have responsibilities in terms of confidence and identity. They must be confident as native speakers and identify with other native speakers. That is precisely what is required in acquiring any new ethnicity.

8. Related Terms

To be the native speaker of a language means, in a definition cited in Sect. 3, to speak it 'from your mother's knee' (Bloomfield 1970) as your mother tongue or first language (L1). Such a definition is not straightforward and is difficult to uphold. It is not wholly clear, for example, what is meant by mother tongue and by first language. Other terms used to indicate a claim to a language by an individual are 'dominant language' and 'home language' (Stern 1983, Davies 1991).

8.1 Mother Tongue

The 'mother tongue' is literally just that, the language of the mother, and is based on the reasonable view that a child's first 'significant other' is the mother. However, it is not always straightforward: the role of 'mother' may be taken by some other adult; similarly, the mother, biological or not, may provide bilingual or multilingual input for the child, either because the 'mother' is herself bilingual or because the role of mother is shared by several adults who use more than one language in speaking to the child. To what extent the child's own developing idiolect is identified as that of the mother rather than that of the child's own peer group is a matter for empirical investigation (Ochs 1982).

8.2 First Language

'First language' refers to the language which was first learned. Again, this seems straightforward. One's first language is the language ('tongue') learned from one's mother, biological or not. However, many people live in multilingual societies, and everyone lives in multidialectal society. In such cases, the mother tongue and the first language may be different: it may be that the mother tongue is influenced by peers as well as by parents, or it is more than one language and then it is not easy to decide which one is first; it may be that what is the first language changes over time. For example, a young child for whom Welsh is the mother tongue, and the first language in the sense of time of learning, may gradually come to use English more and more and relegate Welsh to a childhood experience: it may not be completely forgotten but is in some sense no longer as useful, no longer generative or creative, and therefore no longer *first*. For the large number of

515

people in this category, the mother tongue is no longer the first or dominant language. Alternatively, such people may claim to have more than one first language. In the case of the bilingual or multilingual or dialectal mother, if it is accepted that one's mother tongue is the code of the individual mother and is not isomorphic with any one or more language, then it may be surmized that what mothers speak is either an interlanguage (see *Interlanguage*) (Selinker 1992) or a set of semilingual (see *Semilingualism*) codes (Martin-Jones and Romaine 1986).

8.3 Dominant Language

The term 'dominant language' is linked because of the underlying assumption that what was one's first language can change over time and another code take its place as one's first language. This must be the case of the child speaking a localized language who moves through education or some other major life-change into a situation in which they use English, French, or some other language of wider communication for most if not all purposes. In such cases, it is English or French which is dominant outside the home while the mother tongue is still dominant at home. In other words, the child has more than one dominant language, each language being dominant in certain areas of life (see Singh 1998).

8.4 Home Language

The 'home language' is the language of the home (and may, as with mother tongue, in reality be a mixed language or a set of languages/dialects) (see *Code-switching: Overview*; *Intertwined Languages*). Home language is defined negatively in terms of what it is not, since it is perhaps easier to define the public code, which often is a recognized (and described) standard English, French, and so on. The home language then is—for many children—what is left after the public, standard code has been removed. At the same time, for some children, the standard code is also the home language. Thus, in the case of middle-class native English speakers, the home language may well be largely identical with official Standard English, which is used as the medium in schools and is taught to foreigners (this applies equally in the UK, the USA, Australia, and other metropolitan, native English-speaking countries).

All these terms can be defined in relation to what they are not: first language in relation to a second language; dominant language in relation to the language it has superseded; home language in relation to the official code; and mother tongue in relation to what one's peers are speaking. The term native speaker tends to be used in each of these ways, for having language X as one's mother tongue, as one's first language, as one's dominant language, or as one's home language.

8.5 Linguistic Competence

Other terms invoked as being relevant to the native speaker are 'competence,' both linguistic and communicative, and '*langue*,' an older term. Saussure's use of *langue* (Saussure 1966) was an attempt to define not the native speaker but what it is that is shared by a language community.

The related notion of competence was introduced by Chomsky (1965) both to specify the knowledge of an indiviual which enables language acquisition to take place and also to signify the goal of linguistic theory. The notion of linguistic competence moves the argument one stage onwards, in that it seeks to answer the question of whether competence needs to assume a community langue.

There are two answers to this question. The first is that competence is about idealized speakers; indeed, Chomsky's definition of linguistics as being about the idealized native speaker in a homogeneous speech community is of obvious relevance. Such an approach is not a social one; it takes no account of situation, purpose, domain, or variety. It is psycho-linguistic or cognitive–scientific and linked to the computer analog for the brain. However, even so extreme and rigorous a view must take some account of limited social aspects, since any eliciting of data, and even the concept of the idealized native speaker, must mean that there is some account being taken of the speaking world. Otherwise, it would be possible for someone who does not know the language or whose speech is full of performance errors of a severe kind or who is aphasic to be used for elicitation, and clearly that is not what happens. So, even here, there is a tacit assumption that the world is made up of speech communities of more than one person. Or, to use Coulmas's image, the double life of the native speaker does come together on occasion; the idealization can put on flesh and blood (Coulmas 1981: 10).

The second answer to the question of whether competence needs to assume langue is that it does because language itself needs an explanation as to how it is that (native) speakers understand one another. In other words, what competence sets out to do is indeed to provide a description of langue.

8.6 Communicative Competence

Chomsky's insistence on examining competence without social factors has been challenged by such anthropologically minded linguists as Halliday (1978) and Hymes (1970, 1989). Hymes proposed the term 'communicative competence' (see *Hymes, Dell Hathaway*; *Communicative Competence*) in order to point to the learned knowledge of cultural norms which is crucial to language use. The position taken up by communicative competence is that knowing what to say is never enough; it is also necessary to

know how to say it. By 'how' here is not meant the performing of the speech, that is, getting the words out, but rather, the using of the appropriate register, variety, code, script, formula, tone, and formality. Once again, the issue for consideration is to what extent such cultural knowledge can be acquired late, and to what extent getting it right, that is, using the appropriate forms, privileges native speakers.

8.7 Second and Foreign Language

The discussion above, of defining the mother tongue and the first and dominant language in opposition to, for example, the 'second language,' suggests that one might hope to define in separate and perhaps rigorous ways the second language and the foreign language. However, a second language is in fact defined in terms of a language which is learned after the first language (Stern 1983). Thus, it remains impossible to define the first language except in terms of what is earliest acquired.

A distinction is perhaps useful between the language acquired by a bilingual (or multilingual) child in the home, or in an environment where more than one input is available, and that of the child who acquires a nonhome or nonintimate language in a more public setting (Romaine 1995, Hamers and Blanc 2000). Such a setting is often education, and the term second language is sometimes used to define a situation in which the child is being educated in a language medium which is not the home language. Not that the second language has to be the language of education—it may be the lingua franca of the public environment in which the child begins to grow up (e. g., English in Nepal). What seems to underline the use of the term second language is that it indicates a command which is less than that of the first language, but stronger than that of the foreign language.

Foreign languages, then, seem to be acquired in order to interact with foreigners, that is, groups outside one's native environment. That also seems to imply that a foreign language does not carry with it the kind of automatic grasp of its systems that are appealed to in terms of the first language and are suggested in some areas of the second language. A foreign language has not been, it can be surmized, internalized in the same way that a first (and perhaps a second) language has. A foreign-language speaker cannot be appealed to for authoritative pronouncements about the language's rules and its use. First-language speakers, of course, can be, and this is the problematic and very interesting issue about second languages: whether control of a second language can become as internalized as the first; whether being a native speaker and being a first-language speaker (or a mother-tongue speaker) are synonymous; and whether a second-language speaker can be a native speaker of that second language.

9. Defining the Native Speaker

To attempt a definition, the native speaker may be characterized in six ways. The native speaker:

(a) acquires the L1 of which they are a native speaker in childhood;

(b) has intuitions (in terms of acceptability and productiveness) about their idiolectal grammar;

(c) has intuitions about those features of the standard language grammar which are distinct from their idiolectal grammar;

(d) has a unique capacity to produce fluent spontaneous discourse, which exhibits pauses mainly at clause boundaries (the 'one clause at a time' facility), which is facilitated by a huge memory stock of complete lexical items (Pawley and Syder 1983); and in both production and comprehension the native speaker exhibits a wide range of communicative competence;

(e) has a unique capacity to write creatively (and this includes, of course, literature at all levels from jokes to epics, metaphor to novels);

(f) has a unique capacity to interpret and translate into the L1 of which they are a native speaker. Disagreements about an individual's capacity are likely to stem from a dispute about the standard language.

In considering the extent to which the L2 learner can become a target-language native speaker, one can again consider the six criteria.

(a) *Childhood acquistion.* The second-language learner, by this definition, does not acquire the target language in early childhood. If they do, then they are a native speaker of both L1 and the target language (TL).

(b) *Intuitions about idiolectal grammar.* It must be possible, with sufficient contact and practice, for the second-language learner to gain access to intuitions about their own idiolectal grammar of the target language.

(c) *Intuitions about group language grammar.* Again with sufficient contact and practice, the second-language learner can gain access to the standard grammar of the target language. Indeed, in many formal learning situations, it is exactly through exposure to a TL standard grammar that the TL idiolectal grammar emerges, the reverse of the L1 development.

(d) *Discourse in the language classroom and pragmatic control.* This may indeed be a descriptive difference between a native speaker and a nonnative speaker, but it is not in any way explanatory—that is to say, it in no way argues that a second-language learner cannot become a native speaker.

(e) *Creative performance.* With practice it must be possible for a second-language learner to

517

become an accepted creative writer in the TL. There are, of course, well-known examples of such cases, for example, Conrad, Beckett, Senghor; but there is also the interesting problem of the acceptability to the L1 community of the second-language learner's creative writing. This is an attitudinal question, but so too is the question of the acceptability to the same community of a creative writer writing in an alternative standard language (e.g., Scots).

(f) *Interpreting and translating.* This must be possible even though international organizations generally require that interpreters should interpret into their L1.

All except (a) are contingent issues. In that way, the question of whether a second-language learner can become a native speaker of a target language reduces to whether it is necessary to acquire a code in early childhood in order to be a native speaker of that code. To answer that question is to ask a further question, about what it is that the child acquires in acquiring his/her L1. However, that question has already been answered in criteria (b)–(f) above, and so the question again becomes a contingent one.

No doubt there is a need to ensure in addition a cultural dimension, that is, (b) and (c) above, since the child L1 acquirer does have access to the resources of the culture attached to the language and particularly to those learnt and encoded or even imprinted early. Still, there are always subcultural differences, for example, between the Scots and the English; different cultures with the same standard language (e.g., the German-speaking European nations); and different cultures with different standard languages (e.g., the British and the American). There is also International English, and isolated L1s in multilingual settings, for example, Indian English. Given such interlingual differences and the lack of agreement and norms that certainly occur among such groups, it does appear that the second-language learner has a difficult but not impossible task to become a native speaker of a target language.

10. Coppieters's Results

Such a conclusion is probably more sociological than linguistic or psychological. For, in addition to the tension referred to between the ideal and the flesh-and-blood approaches to the native speaker, there is a further opposition between the sociological and the psychological views; they are not easily reconcilable. Coppieters points out the lack of fit in his account of a grammatical judgment experiment (Coppieters 1987). He took a group of 27 non-native adult speakers of French who had 'so thoroughly mastered French that it was no longer clearly possible to distinguish them from native speakers by mistakes which they made, or by the restricted nature of their

choice of words and constructions' (1987: 544). For baseline data, he took 20 native speakers of French, matched with the experimental group as far as possible. He used 107 sentences illustrating various aspects of French and asked his subjects individually for acceptability judgments. His results indicated that the two groups belonged to two different populations, with no overlap between, even at extremes. Even so, he accepted an argument in favor of identity theory (Tajfel 1981): 'A speaker of French is someone who is accepted as such by the community referred to as that of French speakers, not someone who is endowed with a specific formal underlying linguistic system.'

However, for Coppieters, such an argument is strongly sociological, and, in his view, competence must include a psychological dimension. He continues: 'it is also clear that the variation between native speakers and non-native speakers cannot simply be subsumed as a special case of the variation among native speakers: that is non-native speakers have been found to lie outside the boundaries of native speaker variation' (1987: 545). Native speakers, reports Coppieters, 'did not need the help of an explicit context. No matter how skilful non-native speakers might be at deriving the appropriate interpretation of a sentence in context, their inability to do so in the absence of an explicit context indicates a fundamental difference between their knowledge of the language and that of native speakers' (1987: 566–7).

Given the idiolectal and dialectal differences among native speakers themselves, Coppieters's claim is a strong one: his argument for cognitive rather than formal dissonance between native and non-native speakers concerns the grammar of the standard or common language learned before the critical period (Lenneberg 1967). His view is widely shared among psycholinguists and second-language researchers (Gass and Varonis 1985).

11. The Native-speaker Myth

Coppieters represents the uncompromising psychological view. According to that, the native speaker is defined by early acquired knowledge. Bartsch (1988) takes the more sociological view, allowing for the importance of attitude and identity. Although both views concern control of the standard language, they are probably not reconcilable. Nevertheless, the concept of native speaker is used entirely appropriately in these quite different ways. It is probable that what is most enduring about the concept has nothing to do with truth and reality, whether or not individuals are native speakers; what matters most is the enduring native speaker myth combining both knowledge and identity: in that myth, the two views have an equal role.

But there are those who disagree; Birdsong (1992) disputes the claim that the learner's 'ultimate attainment' can never be equal to native speaker

competence, concluding from his partial replication of Coppieters' study that 'ultimate attainment by nonnatives can coincide with that of natives' (1987: 739). Such non-natives are, of course, exceptional learners, but the fact of their success indicates that the native speaker is as much a sociolinguistic construct as a developmental one. Birdsong's conclusion is supported by Bialystok (1997) who queries the role of maturational factors in second language acquisition.

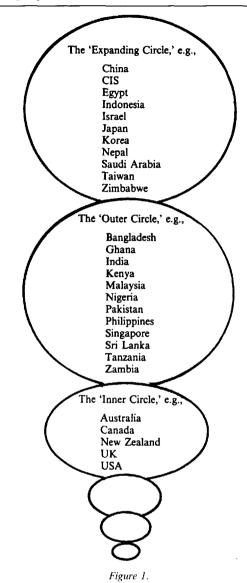
New Englishes


B. B. Kachru

The 'New Englishes' are the result of the global spread of English during the Colonial period. It was during this period that English gained the status of an international language and left other competing natural and artificial languages behind (e.g., French and Esperanto). There are now considerably more non-native users of English than native users, and it is the non-natives who have become the instruments for the continued spread of the language.

1. The Diffusion of English and Its Concentric Circles

The diffusion of English is best captured in terms of three concentric circles: the Inner Circle, the Outer Circle, and the Expanding Circle. The Inner Circle

519

Figure 1.

represents the traditional historical and sociolinguistic bases of English in the regions where it is used as a native or first language. The Outer Circle represents the regions of the world formerly colonized by Britain and the USA; in those regions English was the language of empire building. The Expanding Circle includes the areas in which English is primarily a foreign language (see Fig. 1).

2. Terminology

The term 'New Englishes' is primarily used for the varieties of English which have developed in the Outer Circle. All such varieties—which exist in

practically every continent—are transplanted and have therefore also been labeled 'diaspora' varieties (Kachru 1992a). The use of the term 'new' is a misnomer; in a historical and linguistic sense these varieties are not new. In South Asia, English was institutionalized in 1835 with the Minute of Thomas B. Macauley (1800–59). English also has a long his-tory in parts of Africa and Southeast Asia. The 'new-ness' of these varieties lies in the recent recognition of their linguistic and literary institutionalization.

From the 1960s these varieties attracted the serious attention of scholars working in the fields of linguistics, sociolinguistics, lexicography, language acquisition, and literature. The New Englishes have a long history of acculturation in geographical, cultural, and linguistic contexts, quite different from the developments of English in the Inner Circle.

The term 'World Englishes' is a synonym for 'New Englishes,' one which I now prefer. It symbolizes formal and functional variation, diverse sociolinguistic and pragmatic contexts, and canons and canonicities that the English language embodies in its global multilingual and multicultural contexts. The emphasis is on pluralism, not on the dichotomy between 'us and them,' 'native and non-native.' This perspective demands re-evaluation of traditional theoretical, methodological, literary, and ideological conceptualizations of the study of the English language. The term is not to be confused with World English, used earlier by Tom MacArthur among others. World Englishes implies 'the democratization of attitudes to English everywhere in the globe, in the process questioning the received model of the English as Native Language, English as Second Language, and English as Foreign Language nations...This is a more dynamic model than the standard version... [which] suggests mobility and flux and implies that a new history is in the making' (MacArthur 1993: 334).

3. Users and Functions of New Englishes

An estimated 130 million speakers in the Outer Circle use English with one or more other languages. This conservative figure considers only 10 percent of the total population in this circle as English-knowing. The term 'English-knowing' is rather tricky, since there is a cline of competence in the use of English. One end of the cline includes users of educated English; at the other end are those whose English has been characterized as 'broken.'

All the countries in the Outer Circle, for example, India, Nigeria, Singapore, Zambia, and the Philippines, are multilingual and multicultural, and English has official status in their national language policies as a language of wider communication across ethnic and linguistic groups. The Indian Constitution recognizes English as an 'associate' official language; in Nigeria and Zambia, English is one of the state

languages; and in Singapore and the Philippines, English continues to be a major language of education, the legal system, and administration. In all these regions English, in various forms, plays an important role in interpersonal interaction and in literary creativity.

The New Englishes have thus penetrated deep into the societies of the Outer Circle. This societal penetration has resulted in the development of several subvarieties, ranging from educated to pidginized, e.g., Nigerian pidgin in West Africa, basilectal or colloquial English in Singapore, Hong Kong, and Malaysia, and Babu English and Butler English in India and Pakistan. In these countries English also plays a vital *intra*national communicative function as a link language; the *inter*national role, though important, is secondary.

The New Englishes continue to have an instrumental function in higher education, particularly in science and technology, and as a pan-regional language. They have a regulative function in national and intranational trade and commerce, in the network of national administrative and military service, and in the higher legal system. English is an important language for the media and for sociopolitical discourse.

4. The New Englishes as 'Contact' and 'Interference' Varieties

In the literature, two other terms are used to refer to the New Englishes: 'contact' varieties and 'interference,' varieties (see *Language Transfer and Substrates*). The term 'contact' highlights the multicultural and multilingual contexts in which these Englishes are used, and the impact of local sociolinguistic contexts on these varieties. The impact—or to use a more precise term 'transfer'—manifests itself in pronunciation, lexis, grammar, discourse, speech acts, and stylistic strategies. The new Englishes have thus acquired distinct linguistic and cultural identities. This has resulted in the expansion of the literary and sociocultural canon of English. These distinct canons of the New Englishes are not identical to the Judeo–Christian canon, traditionally associated with English literature and language (Kachru 1992a).

The degree of localization of English determines the depth of impact at various linguistic levels in each variety of English. The resultant linguistic processes have been termed, for example, the 'Africanization' and the 'Indianization' of the English language. The major contact varieties of English include South Asian English, West African English, Singapore English, and Philippine English (see Bailey and Görlach 1982, Kachru 1986).

The term 'interference' varieties is another way of describing the phenomenon of language contact: it refers to the linguistic readjustments in the bilinguals' use of English. The bilinguals' readjustment shows in the transfer of features of a dominant language on pronunciation, grammar, vocabulary, and discoursal features. Quirk et al. (1985: 27–8) consider interference varieties of English '... so widespread in a community and of such long standing that they may be thought stable and adequate enough to be institutionalized and hence to be regarded as varieties of English in their own right rather than stages on the way to more native-like English.' Each variety thus has stable identificational features.

4.1 Identificational Features

The identificational features of the New Englishes are of two types: those which entail transfer from a local language into English, and result in distinct phonetic, grammatical, or discoursal characteristics, and those which are essentially lexical and result in lexical transfer. The earlier research on transfer was primarily restricted to pronunciation and vocabulary. However, in recent research, the concentration has been on syntax, discourse, and interactional contexts (Smith 1987), the aim being to investigate variety-specific nativization (e.g., Nigerian English) and area-specific characteristics (e.g., African English, South Asian English). In certain ways all the New Englishes share several productive processes (Platt et al. 1984). The following characteristics are illustrative.

4.1.1 Pronunciation

The native varieties of English generally use stress-timed rhythm, i.e., stressed syllables occur after identical intervals. On the other hand, the New Englishes in South Asia (e.g., India, Pakistan, Sri Lanka), Southeast Asia (e.g., Singapore, Malaysia, Hong Kong), and West Africa (e.g., Nigeria, Ghana) generally use syllable-timed rhythm, i.e., an arrangement of equal numbers of syllables per unit of time. This difference is one of the factors which causes problems in intelligibility.

4.1.2 Grammar

A number of grammatical features are typical of a variety and of a region. In South Asian English there is a tendency to form interrogative questions without changing the position of the subject and auxiliary items (e.g., *What you would like to eat? When you would like to go?*). In South Asian and African English *isn't it?* is used as a universal tag (e.g., *He isn't coming, isn't it? You are not going tomorrow, isn't it?*). The use of articles and complementation also shows several differences in the new varieties (see Bailey and Görlach 1982, Cheshire 1991, Kachru 1992a, 1992b).

4.1.3 Lexis

The lexical features are of two types. The first type includes those items which are borrowed (see *Borrowing*) from the local languages. A small number

of such lexical items are shared with British and/or American English (e.g., *pundit, nirvana, guru*). In local varieties of English, however, such items are used extensively (e.g., in South Asian English *jantā* 'people,' *gāḍī* 'train'; in South African English *kloof* 'ravine, valley,' *skorokoro* 'jalopy'; and in Singaporean/Malaysian English *makan* 'food,' *kampong* 'a small settlement'). The new Englishes make frequent use of such items in conversation, newspapers, and in creative writing. The second type includes hybridized items, in which local language items are mixed with English to create new words (e.g., *lathi charge* 'charge with baton,' *tiffin carrier* (*tiffin* 'snack,' 'light meal') in South Asian English *dunno drums* 'a type of drum,' *kraal family* 'family sharing the same enclosure' in South African English).

4.1.4 Collocations

These include translations of contextually appropriate local words into English. This type of lexical innovation marks the functional acculturation of the New Englishes in local—that is African and Asian—sociocultural contexts. For example, the use of *twice-born* 'one who has been initiated as a Brahmin,' *co-brother-in-law* 'wife's sister's husband,' *cow-worship* 'worship of cows' in South Asian English; and *cry die* 'wake, funeral rites,' *head tie* 'head scarf,' *throw water* 'offer a bribe,' and *co-wife* 'the second of two wives' in African English.

4.1.5 Idioms

A vast number of idioms and comparative constructions are translated from local languages, e.g., *to whisper together* 'to talk privately,' and *to have no shadow* 'to have no courage,' in African English; and *as honest as an elephant* and *as good as kitchen ashes* in Indian English.

4.1.6 Discourse and Style

This refers to the use of localized speech acts, and discoursal and stylistic strategies. The innovation of such culture-bound discourse strategies in interaction and in literary creativity has given a distinct identity to the New Englishes (Kachru 1986: 159–73, Smith 1987) (see *Discourse in Cross-linguistic and Cross-cultural Contexts*).

4.1.7 'Mixing' and 'Switching'

The processes of code-mixing and code-switching (see *Code-switching: Overview*) are distinctive markers of the multilinguals' creativity in New Englishes. Mixing entails hybridization by using words or larger units from local languages in the stream of discourse in English (e.g., English–Hindi mixing in *der ho rahī hai, let us lagāo khānā* 'It is getting late, let's set out the food'). Code-switching involves changing from one language to another (e.g., English to Swahili). The motivations for mixing and switching are varied, e.g., marking identity, function, participants, settings.

4.2 Varieties within a Variety

The varieties of New Englishes are not homogeneous. Institutionalization over an extended period and various societal functions of the variety have resulted in a cline of varieties. The institutionalized New Englishes have an educated variety, and several other subvarieties. The subvarieties are based on proficiency (e.g., Butler English or Bazaar English in South Asia, Nigerian Pidgin in West Africa); societal level (e.g., basilect or colloquial English in Singapore and Malaysia); ethnic identity (e.g., Anglo–Indian English in India, Igbo English in Nigeria, Burger English in Sri Lanka); geographical area (e.g., Bengali English); and schooling (e.g., Convent English in South Asia).

5. Norms and Models for New Englishes

The question of norms and models has become a major concern with the universalization and consequent diversification of English. The issue has several dimensions: pedagogical, attitudinal, pragmatic, social, and linguistic (Kachru 1992b).

There are three types of speech fellowships of English: the norm-providing (the Inner Circle); the norm-developing (the Outer Circle); and the norm-dependent (the Expanding Circle).

In the Outer Circle, endocentric norms have well-recognized linguistic, literary, and cultural identities. The controversy, however, has not completely abated. In this Circle there is an ongoing debate between the appropriateness and pragmatics of local and external norms—a conflict between language behavior and attitude. In the Expanding Circle, the pedagogical models (norms) continue to be external, the choice being primarily between the general American and the educated British varieties.

6. Literary Creativity in New Englishes

The New Englishes have vibrant and fast-developing literary dimensions (King 1980). This literary tradition has developed in all the countries in the Outer Circle. The nativized literary traditions are now considered part of the local literary tradition and national literatures. This body of literature includes various genres: novel, short story, poetry, essay, and journalism. The localized identity of these literatures is reflected in modifiers such as Nigerian English literature, Indian English literature, and Singaporean English literature. In such creativity, various types of linguistic and stylistic experiments and innovations are made. These literatures are primarily the result of linguistic and sociocultural contact of two or more languages and cultures, and are thus appropriately considered as products of bilinguals' creativity (Kachru 1986). In designing such texts the linguistic

resources of two or more, related or unrelated, languages are used. This is often done consciously as in Chinua Achebe, Salman Rushdie, and Raja Rao.

There are two ways in which the institutionalized contact literatures in English reveal their distinctiveness: 'nativization' and 'acculturation.' Nativization refers to the formal textual features of such creativity, and acculturation to the thematic or contextual localization of such writing. Nativization contributes to linguistic processes which are localized and provide an identity to the text. Indian philospher-novelist Raja Rao's *The Serpent and the Rope* is an example of the Indianized text; and Gabriel Okara's *The Voice* is an example of an Africanized text. On the other hand, acculturation of texts is a matter of cultural identity which English acquires by its Africanization or Indianization. The two processes together mark the New English literatures as being distinct and give them identities separate from the canons associated with British and American literatures. It is in this sense that the New Englishes have expanded the literary and cultural cannons of English. These literatures have received international recognition: Wole Soyinka of Nigeria received the Nobel Prize in literature (1986) as did Derek Alton Walcott of the West Indies (1992), and Raja Rao of India received the Neustadt International Prize (1988).

Contact literatures in English have been studied within three paradigms: linguistic, literary, and padagogical. In linguistic studies, though belated, the shift is from an 'interference-oriented' model to a model based on comparative (contrastive) discourse. Creativity is seen as innovation within non-Judeo–Christian, non-Western contexts (Smith 1987). The emphasis is on the underlying contextual reasons for style shifts, change in lects, and strategies for nativized speech acts and discourse. These stylistic experiments invariably involve transfer from the style repertoire—literary or oral—of local languages. Such creativity in English is now recognized as such by the national literary academies (e.g., in India, Pakistan, Singapore) as an extension of local literary traditions. Padagogical uses of such writing are discussed in courses on stylistics, and in cross-cultural uses of English.

7. Ideology and Methodology

The development of New Englishes, and their distinct identities raises a string of ideological, theoretical, and methodological questions (Kachru 1988). These questions have come into the forefront for two reasons: the use of sociolinguistic models for the study and understanding of New Englishes and attempts to relate innovations to their social meaning; and the study of the New English literatures as extensions of the local literary traditions. There is a

trend toward breaking away from the Eurocentric approaches, and new creativity is essentially considered in local and particular contexts. Achebe (1975: 11) argues, 'I should like to see the word *universal* banned altogether from discussions of African literature until such a time as people cease to use it as a synonym for the narrow, self-serving parochialism of Europe.'

What is the relationship between the medium and the ideological message? Do the New Englishes represent the Western or local cultural ethos? Can the medium be localized and molded to have new cultural and ideological identities and develop new canons? In other words, what are the processes used for the 'decolonization' of English (Thumboo 1988)? These questions continue to be debated. In methodological terms, one asks: how insightful are the research methodologies used for monolingual societies and their creativity for understanding the innovations and creativity of linguistically and culturally pluralistic societies?

All these questions are invariably related to a wider question of the power and politics of English and various manifestations of such strategies for power (Kachru 1986, Phillipson 1992, Tollefson 1991) (see *Linguistic Imperialism*).

8. Current Issues

The major issues concerning the New Englishes relate to four aspects. First, the implications of 'pluricentricity' and 'diversification' of English on international and intranational intelligibility and its implications for the English language and literature. Second, strategies for codification and its consequences. Third, attitudes toward the diversification and 'multi-identities' of Englishes. Fourth, the implication of new literary and linguistic canons and their impact on mutual intelligibility.

9. Resources

The period following the 1980s has been the most active period for research and debate on World Englishes in general and the New Englishes in particular. An overview of such research is provided in compilations (Cheshire 1991, Kachru 1992b, Viereck et al. 1984); and in state-of-the-art surveys (e.g., Kachru 1992a).

Pidgins and Creoles: An Overview
L. Todd

In 1953, the pidgin English of Papua New Guinea was described as 'inferiority made half articulate' and its grammar was criticized as 'crude and incredibly tortuous' (French 1953). In the last decade of the century, the same language is called Tok Pisin (Talk Pidgin): it is the chosen language of debate in Port Moresby's parliament; it is employed for news and entertainment on the media; it is officially recognized in the constitution as one of the country's national languages; it is used in official speeches by visiting dignitaries; and it is spoken as a mother tongue by over 20,000 Papua New Guineans and as a lingua franca by an estimated 1.5 million people. The change in the status of Tok Pisin resembles the change in attitude towards pidgin and creole languages generally. In the period between 1950 and 1975, these languages stopped being described and dismissed as 'marginal languages' and 'bastardized jargons,' and became central to linguistic discussion on acquisition of language linguistic universals, and language change.

1. Definitions

It seems likely that 'pidginization,' a process of simplification and hybridization, is as old as contacts involving speakers of different languages or dialects. Many contemporary pidgins and creoles can, however, be traced back to European 'discoveries' in the sixteenth and seventeenth centuries, a period of linguistic procreation, when new languages came into being, languages which are lexically related to Dutch, English, French, Portuguese, and Spanish, and which are spoken in the late twentieth century, in some form, by perhaps 100 million people. (It is not easy to estimate the number of speakers of pidgins and creoles, but this figure may be seen as conservative when it is pointed out that Afrikaans, a semi-creolized Dutch, is spoken by over 5 million, Cape Verde Crioulo by over 3 million, Haitian Créole by over 5 million, Nigerian pidgin English by over 20 million, and Tok Pisin by 1.5 million.)

The origins of the word 'pidgin' are still debated. It is possible that it derives from *Pidian* (South American Indian), from a Chinese pronunciation of

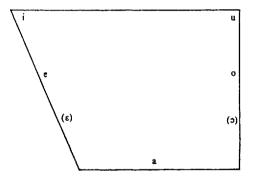
524

English *business* or Portuguese *ocupaçao* (business), from Hebrew *pidjom* (barter), from Portuguese *pequeno* (little, and suggesting baby talk), or from a combination of any of these, reinforced by English *pigeon*. The term is applied to a lingua franca which develops as a simple means of communication between people speaking different languages. 'Creole' derives ultimately from Latin *creare* (to beget) and more immediately from Portuguese *crioulo*, Spanish *criollo* and French *créole*. The term 'creole' was applied to Europeans who were born in the New World, then to Africans born there, to both, to people of mixed race, to the forms of language spoken by people in the Americas, and eventually, to any pidgin which has become a mother tongue for a community.

2. Social Attitudes

Pidgins and creoles used to be stigmatized. There are three main reasons for this. First, their speakers were usually non-Caucasian, slaves or servants, and their low prestige was transferred to the languages they spoke. (The metaphors used to describe the languages provide insights into the asymmetry of the human relationships. Individual languages were described and dismissed as a 'barbarous dissonance,' a 'bastardized language,' and a 'mongrel lingo.') Second, they tended to be spoken only, and therefore lacked the status of languages with long literary traditions. Third, many were recognizable as varieties of European languages, and were presented as simplified or corrupted versions of these. The technique of using modified European orthographies for pidgins and creoles reinforced the notion that they were imperfect versions of metropolitan languages:

> Littee Jack Horner
> Makee sit inside corner,
> Chow-chow he Clismas pie;
> He put inside t'um,
> Hab catchee one plum,
> 'Hai yah! what one good chilo my!'
>
> (Leland 1876: 75.)

3. Widespread Nature of Pidgins and Creoles


As has been shown, many pidgins and creoles can be traced to the period of European exploration and colonization, but others evolved outside such contacts. Pidgins and creoles have developed in multilingual societies in every continent. In Papua New Guinea, for example, Hiri Motu came into being prior to European contacts to facilitate trade between speakers of Motu and other Papuan languages; in Indonesia and Malaysia, the so-called 'Bazaar Malay' has had widespread currency among travelers and traders for at least four centuries; in

India, in the State of Assam, which recognizes 13 distinct languages, Naga Pidgin, a form of Assamese, continues to have value in interlingual contacts; in the Central African Republic, Sango arose from contacts between speakers of mutually unintelligible African languages; in England, Anglo-Romani, a creolized form of Romani, has evolved; and in America, there is evidence of pidginization of Amerindian languages. It seems likely that a form of Chinook Jargon (see *Jargons*) existed as a link language between speakers of Chinook and Nootka before it was used as a lingua franca by speakers of French and English. Pidginization is widely found in all contacts involving speakers of different languages; marginal pidgins develop when simple communications across linguistic barriers are regular but superficial; elaborated pidgins come into being to facilitate long-term but non-intimate communications between people; creoles arise when pidgins become mother tongues.

4. Characteristics of Pidgins

Pidgins and creoles are found throughout the world and are lexically related to languages from virtually all the world's language families. They are classified together because of sociological and linguistic criteria. Stable pidgins share the following characteristics:

(a) Phonologically, they are simpler than any of the languages involved in their evolution. Often, they have a five- or seven-vowel system, as shown below.

Nasalized and rounded front vowels are avoided, as are dental and lateral fricatives and clicks, even if they occur in one or more of the donor languages.

(b) They have a small vocabulary, drawn mainly from the language of the socially dominant group. English-based pidgins, for example, derive as much as 90 percent of their lexicon from English:

English	Kamtok (Cameroon)	Tok Pisin
arm, hand	*han*	*han*
back, return	*bak*	*bak(im)*

become pregnant	*gɛt bɛlɛ*	*gatim bel*
blood	*blɔd*	*blut*
stomach, seat of emotions	*bɛlɛ*	*bel*
come	*kam*	*kam*
give	*gif*	*gifim*
go	*go*	*go*

(c) Most words are polysemous. Kamtok's *hia* (<hear), for example, means 'hear,' 'sense,' 'understand.'

(d) Most words are multifunctional. Kamtok's *bad* (<bad) can function as an adjective:

tu bad pikin (two bad children)

as a noun:

Wi no laik dis kain bad. (We do not like this kind of badness.)

as an adverb, modifying a verb:

A laikam bad. (I like it very much.)

as an adverb, modifying an adjective-verb:

I gud bad. (He's very good.)

as an adjective-verb:

Di pikin bad. (The child is bad.)

(e) Emphasis is often indicated by reduplication:

Kamtok	*big* (big)	*big big* (enormous)
	luk (see)	*luk luk* (stare at)
Petit Nègre	*gran* (big)	*gran gran* (enormous)
	vwa (see)	*vwa vwa* (stare at)

(f) They often have a small number of prepositions, sometimes as few as two, one to indicate location, another to indicate possession. In Tok Pisin, for example, the two most frequently used are *long* (<along) and *bilong* (<belong):

Mi stei long Mosbi. (I live in Port Moresby.)
haus bilong mi (my house)
haus bilong wanpela meri (a woman's house).

(g) Abstractions are often indicated by compounds. In Kamtok, for example, one finds:

big ai (<big + eye) = greed, greedy
drai ai (<dry + eye) = brave, bravery (in a man), brazen, brazenness (in a woman)

and in Tok Pisin, there is:

big maus (<big + mouth) = conceit, conceited
drai bun (<dry + bone) = tough, toughness.

(h) Word order is rigid. In many pidgins, including Kamtok, it follows the pattern of:

(Adjunct) + Subject + Predicate + (Object) + (Adjunct)
Las nait wi bin si wi papa fɔ haus

Last night we saw (visited) our father in his house.
Wɛti yu di fain jɔsnau?

What are you looking for now?
Wuna go kwik kwik.
Go immediately.

(i) Inflection is nonexistent or minimal:

Kamtok	Tok Pisin	English
wan man	*wanpela man*	one man
tu man	*tupela man*	two men
a go	*mi go*	I go
i go	*em i go*	he/she/it goes
wi go	*mipela go*	we go
yu bin go	*yu go pinis*	you (sg) went
wuna go go	*bai yupela go*	you (pl) will go
a go go?	*bai mi go?*	Shall I go?

(j) Temporal and aspectual distinctions are indicated by context, by an adjunct, or by a set of auxiliaries which occur in a fixed order:

ɛni dei ɛni dei, a mek chɔp. (Every single day, I cook.)
Las nait, a mek chɔp. (Last night, I cooked.)
Wɛti a bin du? A bin mek chɔp. (What did I do? I cooked.)
A bin di soso mek chɔp. (I was invariably cooking.)
Smɔl taim a go mek chɔp. (In a little while, I'll cook.)

(k) Negation is usually indicated by placing a negator before the verb:

Kamtok	Tok Pisin	English
Kam	*Kam*	Come
No kam	*No kam*	Don't come
I no kam	*Em i no kam*	He isn't coming/hasn't come

Multiple negation is common as a form of emphasis.

No man no laik mi no smɔl. (Nobody likes me at all.)

When a pidgin is creolized, its simple structure is often carried over, but a mother tongue must be able to fulfill all its speakers' linguistic needs and so the vocabulary expanded, polysemy reduced, additional prepositions introduced, and the syntax made less dependent on context.

5. The Origin of Pidgins

Each pidgin and creole derives most of its vocabulary from a single language. Those that share their core vocabulary with English are called 'English-based' or are said to have English as their 'superstrate' or their 'lexical source language.' If one looks at phonological or syntactic data, however, the classification is much less easy. French is the lexical source language for Haitian Créole, for example, but if one compares some of its structures with those of Kamtok, one sees that they share similarities not shared by French and English:

Li bel. = Il/elle est beau/belle. (lit. 3rd person pronoun (pers pron) + lovely)
I fain. = He/she/it is handsome/pretty. (lit. 3rd pers pron + lovely)

Li bel? = Est-il/elle beau/belle? (lit. 3rd pers pron + lovely + rising intonation)

I fain? = Is he/she handsome/pretty? (lit. 3rd pers pron + lovely + rising intonation)

Li te kone... = Il/elle connaissait... (lit. 3rd pers pron + past time marker + base form of verb)

I bin sabi... = He/she knew (lit. 3rd pers pron + past time marker + base form of verb)

Li pa te kone... = Il/elle ne connaissait pas... (lit. 3rd pers pron + negator + past time marker + base form of verb)

I no bin sabi. = He/she didn't know (lit. 3rd pers pron + negator + past time marker + base form of verb)

Li gro pas u. = Il/elle est plus gros que vous (lit 3rd pers pron + big + pass + you)

I big pas yu. = He/she is bigger than you (lit. 3rd pers pron + big + pass + you).

In addition, some of the pidgins which are lexically unrelated to European languages share structural features with English-based pidgins and creoles:

Ewondo Populaire	Krio	English
Me bo	*A du*	I do
Me ke bo	*A nɔ du*	I don't do
Me nga bo	*A bin du*	I did
Me ke nga bo	*A nɔ bin du*	I didn't do.

The classification of pidgins and creoles causes three main problems. First, the vocabulary points unequivocally to one parent language, whereas the syntax does not. Second, the process of pidginization of European languages has resulted in the wholesale discarding of concord, inflection, and morphology, and these are the very features that are used in showing linguistic relationships. Third, the sound changes which words have undergone in being adopted into pidgins imply a greater passage of time than is actually the case. This point suggests that one must be careful in the rigid application of the findings of glottochronology to language change in the past.

Many theories have been advanced to explain the origin of pidgins, but the three most comprehensive are monogenesis, polygenesis, and linguistic universality.

Monogeneticists suggest that all pidgins related to European languages derive ultimately from *one* Mediterranean trade language, which may have been a form of *Lingua Franca* or *Sabir* (see *Lingua Franca*), the medieval link language between Muslims and Christian Crusaders. This language is referred to many times in books of exploration dating from the seventeenth century. It may have formed the basis of a maritime 'Sailors' Jargon,' which would have been used on board ship and in the ports where many of the pidgins first developed. The structural similarities of pidgins and creoles related to Dutch, English, French, Portuguese, and Spanish would support this theory, as would the facts that all of these languages have nautical elements (for example, Krio's *gali* = kitchen, and Haitian Créole's *mare* = to tie) and share lexical items such as *pikin/pikinini* = child and *sabi* =

know. According to this theory, speakers of a Portuguese pidgin in an African port would have relexified the language towards Dutch, French, or English, depending on the strength of contact with the individual colonial power. Against this theory is the fact that pidgins such as Ewondo Populaire (Cameroon) and Hiri Motu (Papua New Guinea) also share many of the same structural features although they do not derive from European languages.

Polygeneticists suggest that all pidgins and creoles followed independent but parallel developments. The early pidgins related to European languages evolved in conditions of slavery or extreme social deprivation. The European 'masters' would have simplified their language and the 'slaves' would have learned an imperfect version of the target language. Since the differences in social status did not allow for the close linguistic contact that would have enabled the 'slaves' to move beyond their baby-talk version, the simple lingua franca was retained and passed on to subsequent generations. Supporters of this theory account for the structural similarities in two ways. First, they point out that the superstrate languages are all Indo-European and so share deep-rooted similarities. Second, they suggest that all Atlantic pidgins and creoles share a common West African substrate and many of the Pacific varieties share a similar Pacific substrate. It is probably true that many Europeans adopted a condescending linguistic attitude to the peoples of Africa, Asia, Australia, and Polynesia; it is also likely that learners of pidgins used baby-talk strategies in their acquisition of the languages; and it is undoubtedly true that pidgin speakers were influenced by their mother tongues. African pidgins and creoles reveal idioms, metaphors, and proverbs calqued from West African languages:

dei klin (day clean) = dawn
nak han (known hand) = lament, mourn
Wan han no fit tai bɔndul (one hand no fit tie bundle) = People must cooperate.

Equally, pidgin speakers from Papua New Guinea calqued from their vernaculars:

gras bilong ai (grass belong eye) = eyebrow
tu bel (two belly) = doubting
tingting long bel (think think long belly) = reflect.

The difficulty inherent in accepting polygenetic theories of origin is that, while many of the claims are correct or reasonable, they cannot explain the structural similarities found in pidgins which have arisen in different parts of the world, where such pidgins have had little or no connection with European languages.

In an attempt to overcome the difficulties inherent in both monogenetic and polygenetic theories, some

creolists argue that the solution is to be found in a universalist approach. They suggest three main reasons for the structural similarity of pidgins and creoles. First, the social conditions in which pidgins arose are similar. People who did not share a language, and who were often in an asymmetrical relationship, needed to communicate simply and quickly, usually about trade. Second, learning strategies are similar. The baby-talk and 'foreigner talk' of English are structurally similar to those of Arabic and Igbo. Third, human languages are similar and any child can learn any language. The children who learned pidgins as a first language and who lacked an adult mother-tongue model created creoles using their inherent linguistic skills. The comprehensiveness of this theory is its most attractive quality. Africans, Americans, Asians, Europeans, and Polynesians would have used their innate linguistic abilities to create simple communication systems which could be elaborated by having recourse to their mother tongues or to the linguistic common denominators which are thought to underlie all human languages. This theory has thus far been impossible to prove. It is likely that children are genetically programmed with particular attributes to acquire languages. It is also likely that speakers, in contact situations, simplify their languages in particular ways. However, it is impossible to be precise about the character and nature of innate linguistic abilities.

6. The Development of Pidgins

Each pidgin and creole is unique in terms of its origin, uses, and linguistic characteristics, and even closely related varieties, such as Sierra Leone's Krio and Gambia's Aku, differ in pronunciation and lexis. It is possible, however, to distinguish four phases in their development, although it must be stressed that they often overlap. The phases may be described as 'Marginal Contact,' 'Nativization Period,' 'Influence from Dominant Language,' and 'Continuum Phase.'

In the Marginal Contact phase, a makeshift pidgin evolves. It uses a limited vocabulary and short utterances, and communication is facilitated by gesture, mime, frequent repetition, and by speaking loudly and slowly. In this phase all speakers tend to use the phonologies of their mother tongues, although all syllables are likely to be stressed. This type of pidgin can be heard in ports and market places where a language is not shared but where people wish to carry out simple transactions. Several pidgin Englishes of this type have also arisen in times of war, for example in Japan, Korea, and Vietnam in the course of the twentieth century, Makeshift pidgins either die out when they no longer serve a purpose or they become more useful by being stabilized and expanded. They most frequently die

out in bilingual contacts and are most frequently elaborated in multilingual communities.

In the Nativization Phase, the pidgin becomes increasingly valuable as a lingua franca in a multilingual environment between local people who do not share a language. Its vocabulary is expanded so that it can be used for purposes other than trade and, the more it is used, the more flexible and stable it becomes. The phonology tends to be that of one's mother tongue, although uncommon sounds are avoided. The vocabulary is expanded by means of borrowing from indigenous languages:

> *akara* (bean cake, from West Africa)
> *kaikai* (eat, food, from Polynesia)

calquing:

> *chɔpdai* = wake for an old person [eat + die]
> *kraidai* = wake for a young person [cry + die]

compounding core vocabulary to create abstractions:

> *man han* (man + hand) = right
> *wuman han* (women + hand) = left
> *tai han* (tie + hand) = mean, meanness

and reduplication:

> *krai* = cry
> *kraikrai* = cry continuously.

The word order becomes relatively fixed and temporal distinctions are often made. Such distinctions can be illustrated by referring to Fanakalo, formerly called 'Mine Kaffir':

> *hamba* = walk, go
> *mina hamba* = I walk, go
> *yena hamba* = he/she/it walks, goes
> *tina hambile* = we walked, went (ile = past)
> *wena yazi hamba* = you (sg) shall walk, go
> *nina zo hamba* = you (pl) shall walk, go
> *yenazonke funa hamba* = they want to walk, go.

When a pidgin reaches this stage of elaboration, it is capable of being used as a mother tongue. Some pidgins become mother tongues from necessity; others from usefulness. In the past, many of the pidgin speakers on the multilingual plantations in Africa, Australia, and the New World had no option but to use their pidgin as a home language; more recently, urban settlers in both Africa and Papua New Guinea have begun to use the local pidgin as one of the languages of the home, with the result that their children often use the language as one of their mother tongues.

The third phase occurs when the pidgin or creole coexists for a considerable time with a language which is used in government and education. Usually, as in the case of Haitian Créole or Nigerian Pidgin, this is the lexical donor language. In this case, the pidgin or creole is influenced at all

levels by the socially dominant language. One can illustrate such influences by means of Nigerian Pidgin, where different periods of borrowing can be seen:

Early	Late Twentieth Century	English
maʃ		smash
	smail	smile
sukuru		screw
	skram	scram
tori		story
	stia	stair
man pikin	boi	boy
smɔl	yɔŋ	young
tik/stik	tri	tree
dei	bi	existential BE
fɔ haus	at hom	at home
wi papa	aua fada	our father

When the dominant language is not the lexical source language, then it too influences the pidgin or creole, causing a certain amount of relexification. Examples of this can be provided by the three creoles in Surinam. Djuka and Sranan were originally English-based, and Saramaccan seems to have been Portuguese-based. All three creoles show some influence from the country's official language, Dutch. Speakers make use of a voiced palatal fricative in the pronunciation of 'gulle' (guilder). The vocabulary is changing:

Djuka	Sranan	Saramaccan	English	Dutch	Portuguese
ala	ala	ala/tuu	all	alle	todo
beligi	bergi	kukuna	hill	berg	colina
bɔmiki	brɔmki	fɔlɔ	flower	blommetje	flor
dɔti	mɔrsu	dɔti	dirt(y)	mors(ig)	sujo
kaabu	krabu	kaabu	scratch	krab(ben)	arranhao
sikiifi	skifi	sikifi	write	schrijven	escrever

and some overt marking of plurality occurs in nouns.

The Continuum phase is found in all communities where an elaborated pidgin or a creole coexists with its superstrate, especially when this superstrate has national and international status. In such circumstances, an unbroken continuum of forms links the pidgin or creole (known as the 'basilect') to the standard, official language (the 'acrolect') through a series of intermediate forms (the 'mesolect'). In Nigeria, for example, the following is found:

A bin kam, kariam go.
A kɔm, kariam go.
A kɔm, kariam awe.
A kem an kari it awe.
I came and carried it away.

It is possible that a pidgin or creole in an advanced stage of decreolization would become virtually indistinguishable from the lexical source language. Many scholars, for example, believe that American Black English was originally a creole which has been decreolized towards Standard American English (see *Ebonics and African American Vernacular English*).

7. The Early Twenty-first Century Position of Pidgins and Creoles

Pidgins and creoles continue to be spoken by millions of people throughout the world, and so it is only possible to offer broad generalizations. Throughout society, the media, and particularly television, are affecting all nonstandard varieties, causing many to become recessive. Numerous pidgins and creoles, like dialects, are growing closer to the metropolitan norm in pronunciation, lexis, and syntax. This process can be detected in Barbados, Cameroon, India, Nigeria, Papua New Guinea, Sierra Leone, and Queensland, and may be regarded as a speeded-up form of phases three and four.

In an ideal world, where all people had equal access to education and a comfortable standard of living, it could be predicted that pidgins and creoles would gradually merge with the standard form of their lexical source language, perhaps extending that language's cultural and idiomatic repertoire. For some speakers of pidgins and creoles, this is undoubtedly happening, but not for all. There is evidence from urban communities especially in the Caribbean, England, and the United States, that for some speakers the expected decreolization has stopped, and a certain amount of recreolization has occurred. The recreolization is found mostly in the speech of young people who are disaffected or feel neglected by society. In some families in London, for example, it is possible to find grandparents, of Caribbean origin, whose English has fewer creole features than that of their teenage grandsons. Some of these young black people use a variety, referred to by many names including 'Patwa' (<Patois), 'Soul Talk,' and 'Rasta Talk,' as a badge of their cultural identity and values. The variety has much in common with the Creole English of Jamaica, but is not identical with it. Nor is it a direct development of it. Such recreolization may fade or grow stronger depending on social conditions.

It is always difficult to predict future linguistic developments, but perhaps four generalizations can be made. First, pidginization will continue to occur, as it has done throughout recorded history. It will be found in ports, holiday resorts, and youth hostels, where people who do not speak each other's language come into contact. It will also be a feature of contact between local people and a non-local army. Such pidginization may result in a makeshift pidgin if the contact is prolonged. Second, the social upheavals which accompanied slavery and blackbirding, and which were a perfect breeding ground for pidginization and creolization, are unlikely to recur. ('Blackbirding' is the name

given to a system of indentured labor practiced mainly in the nineteenth century. Laborers from many Polynesian islands were taken to plantations, mainly in Queensland. They were on the multilingual plantations for two or three years before being paid and, theoretically, returned to their home island.) It is thus improbable that such widespread development and spread of pidgins and creoles as occurred between the sixteenth and nineteenth centuries will happen again. Third, most speakers of creoles and elaborated pidgins will also control the standard language and will have an extended linguistic repertoire. And fourth, as scholars learn more and more about, and from, pidgins and creoles, these languages will be seen not as linguistic sports, but as keys to the understanding of how languages can develop, evolve, and die. They have already shed light on how Latin was transformed into a family of Romance languages, and how contacts in England caused highly inflected Germanic dialects to develop the creole features that characterize modern English.

Pidgins and Creoles: Models

J. Aitchison

The formation of pidgins, and the way they develop into creoles has attracted a massive amount of interest over the past 20 or so years. Interest was particularly stimulated in the 1980s by the controversial claims of Derek Bickerton (see *Bickerton, Derek*) of the University of Hawaii that creoles reveal the workings of an inbuilt linguistic 'bioprogram,' with which all humans are genetically endowed (Bickerton 1981, 1984). Others argue that pidgins and creoles embody normal processes of change, speeded up by the circumstances of their formation (Aitchison 2001, Arends 1993, Arends and Bruyn 1995). This view presumes that pidgins and creoles primarily represent a sociolinguistic 'mixed language' phenomenon, in which features of a substrate language are combined with those of a superstrate language, with the superstrate's lexicon playing a major role. Below, the 'bioprogram' model will be compared with the newer 'mixed language' model— though both models assume that pidgins and creoles reflect crucial features of the human language 'instinct.'

1. Definitions

A pidgin is a subsidiary language system used for communication by people with no common language. Within this broad definition, most people agree that pidgins have independent rules of their own which cannot be invented by nonspeakers. But a minority assumes that pidgins are a hotchpotch with no real rules, in line with popular ideas that a pidgin is a general name for any type of broken language. Some of the confusion arises because a pidgin is likely to pass through various stages in the course of development: a jargon, prepidgin or minimal pidgin, is likely to become a stable pidgin, which in turn may become an extended pidgin—even though such stages have blurred edges, and merge into one another.

A creole is a pidgin which has become someone's first language, according to its most widely accepted definition, though a minority still use the term to refer to mixed 'full' languages, such as the Spanish-English mix sometimes spoken on the Mexican-USA border. The nature of a creole varies widely depending on the maturity of the pidgin from which it has developed, and some researchers have attempted (controversially) to distinguish 'true creoles' from others (e.g., Bickerton 1981).

Because of the fluid and constantly changing nature of pidgins and creoles, many researchers prefer to talk about processes rather than systems. That is, discussions are carried on under the headings of pidginization (how a pidgin develops), creolization (how a creole develops), and decreolization (how a creole gets reabsorbed into its (superstrate) base), and the tricky question of structural characteristics is therefore avoided.

530

2 Points at Issue

Before the question of models can be settled, other major issues need to be explored. Two repeatedly surface in discussions of pidgins and creoles: the 'universals question' and the 'pidgin vs. creole question.'

2.1 The Universals Question

Most pidgins are overtly adapted from a so-called 'base' or 'superstrate' language, which is different from the language(s) of its speakers, the 'substrate' language(s). For example, Tok Pisin, spoken in Papua New Guinea, is overtly based on English, as in *Yu mas klinim tit bilong yu* 'You must clean your teeth' (from a toothpaste advertisement), although its speakers are mostly native speakers of a local language. A few pidgins and creoles are formed from the mutual adaptation of two equal languages, as possibly in Chinook Jargon, a pidgin of the Pacific Northwest of the USA and Canada, which arose among Indians out of mutual trading needs, as did Russenorsk in North Norway, spoken between Norwegian and Russian fishermen and traders. But whatever their linguistic origin, a wide variety of pidgins and creoles show striking similarities. There is consequently a lively controversy as to how much of any pidgin or creole is derived from the source language(s), and how much is due to independent universal principles.

2.2 Pidgin vs. Creole Question

A crucial question is whether pidgins are fundamentally different in nature from creoles. By definition, pidgins are nobody's first language, while creoles must be someone's first language. Consequently, pidginization is often likened to the reduction and impoverishment which characterizes foreign language learning, and creolization is compared with the apparent naturalness and creativeness of first language acquisition.

The theoretical divide between pidgins and creoles is supported by the 'critical period hypothesis,' the claim that a person's innate language faculty functions only during a limited timespan, and that major language changes are impossible after adolescence. This is being increasingly challenged. There seems to be evidence for a 'sensitive period,' a time when it is particularly advantageous to be exposed to language, especially the sounds. But there is no reason for language learning and language change to come to a shuddering halt (Aitchison 1999). On the contrary, teenagers are particularly prone to altering the language, at least temporarily, and many language changes are now thought to be initiated by adults. This therefore calls into question the assumption that second language speakers are incapable of elaborat-

ing a pidgin, and that creoles are fundamentally different in nature from pidgins.

3 Pidginization: Early Stages

Until relatively recently, little attention was paid to superficially 'broken' language, namely, foreigner talk (speech addressed to non-native speakers; see *Foreigner Talk*), learners' interlanguage (the intermediate forms created by learners en route to a full grasp of a language; see *Interlanguage*), and various jargons (for example, the nautical jargon supposedly once used widely around the world by sailors). But these are likely to form the basis of a pidgin. They turn out to be surprisingly complex phenomena.

The lexicon is of prime importance in incipient pidgins. Morphology is erratic, and often absent. Word order is inconsistent. A possible example of a pre-pidgin is found in the various types of English spoken in India to and by servants at the time when India was part of the British empire, known by names such as 'Butler English,' and 'Kitchen English,' linguistically first reported by the German linguist Hugo Schuchardt (see *Schuchardt, Hugo*), who quoted (for example) a brief Butler English account of a servant who systematically stole quantities of his master's milk:

> Butler's yevery day taking one ollock for own-self, and giving servants all half half ollock; when I am telling that shame for him, he is telling, Master's strictly order all servants for the little milk give it—what can I say, mam, I poor ayah woman.
>
> (Schuchardt 1980: 47)

Studies of the Butler English of a number of Indian domestics, some old, some young, have shown their speech to be fairly inconsistent, but to contain features of pidginization which may be universal (Hosali 2000, Hosali and Aitchison 1985). 'Reduction' was particularly prominent, with numerous 'little words' (auxiliaries, articles, prepositions) and inflectional endings missing, as in: *I poor boy* 'I'm a poor boy,' *I no go Jesus* 'I won't go to heaven.' 'Simplification' (regularization) was also evident, as in a tendency to use *is* for all forms of the verb *be: There is so many people no madam?* 'There are so many people aren't there, madam?' There were also examples of 'overgeneralization,' especially the over-use of 'markers,' features which were felt by speakers to characterize this variety of English, such as *-ing* as an all-purpose verb ending, as in *After I traveling India* 'Afterwards I traveled around India,' as well as a preference for starting a sentence with *is: Is only one father and one brother* 'I have only one father and one brother.' There were also some signs of potential 'reanalysis,' the reinterpretation of an existing linguistic form or structure in a new way, such as the occasional use of *been* as a past tense marker: *I*

been working lots of memsahib 'I worked for lots of European ladies'; and *all* as a plural pronoun or pluralizer: *All is take a nail* 'They (all) took a nail.' None of these processes was applied reliably, and lack of consistency is a recurring finding in studies of foreigner talk and learners' attempts. But they provide the basis on which a pidgin could have been formed.

The universal processes of reduction, simplification, overgeneralization, and reanalysis are directed down particular channels by the nature of the languages involved. For example, in the Butler English studies mentioned above, utterance initial *is* was possibly in origin a conflation of English *he's, I's, it's,* and *if,* perhaps due to the difficulty which speakers of Dravidian languages have in distinguishing these forms. English *been* is a relatively salient form, and *bin/ben* marking pastness or anteriority has emerged independently in several English-based pidgins, for example, *ben* in Jamaican Creole, *bin* in Guyanese Creole and also in Tok Pisin (e.g., Tok Pisin *mi bin go* 'I went'). Similarly, *ol* from *all* is a fairly natural development, and is found both as a pronoun meaning 'they' and a plural prefix in Tok Pisin (e.g., Tok Pisin *ol man* 'the men'). Pastness and plural are two of several common linguistic categories, which tend to emerge early in any language system. Their widespread use may be due to an inbuilt language program, but is more likely to stem from a widespread need in human life everywhere to distinguish between past (or anterior) and non-past (Bybee et al. 1994), and between one and more than one.

Prepidgin phases typically involve 'vertical' influence, the foreigner talk of masters to servants and back (Mühlhäusler 1997). A stable pidgin develops when there is regular 'horizontal' use of the jargon among equals, and when in addition; these users have become removed from the original language model. However, a vertical phase is not essential, since pidgins can arise out of mutual accommodation to one another's speech, as in the case of Chinook Jargon and Russenorsk.

The early pidginization phase indicates that nothing arises out of nothing. The processes of change outlined above—reduction, simplification, overgeneralization, and reanalysis—are ordinary ones, and their effect can be seen in stable pidgins. In Russenorsk, for example, many nouns end in *-a*, as in *silka* 'herring,' *fiska* 'fish,' and many verbs in *-om*, as in *drikkom* 'drink,' *kopom* 'buy,' *slipom* 'sleep.' When two languages are involved, common elements are likely to be retained, and idiosyncratic ones dropped: Russenorsk lost sounds which occur in only one of its languages, so Norwegian *hav* 'sea' became Russenorsk *gav*, and Russian *orech* 'nut' (ending in [x] which is not found in Norwegian) became Russenorsk *oreka*. Russenorsk also retained the subject-word-object word order common to Russian and Norwegian, as in: *moja kopom fiska* 'I buy fish,' *tvoya vegom silka* 'You weigh herring.' Perhaps the main difference between early pidginization changes and 'normal' change is that the processes of change differ in the proportions in which they occur. In early pidgins, reduction, simplification and overgeneralization are likely to be widespread, while reanalysis may be less in evidence.

4. Pidginization: Later Stages

Pidginization tends to be regarded as a special case of foreign language learning. For this reason, many consider pidgins to be of limited interest, and relatively little attention has been paid to their stabilization and extension, due to the unfounded assumption that all major changes must have occurred at the creole stage.

Yet pidgins may develop some quite sophisticated linguistic features. Tok Pisin, spoken in Papua New Guinea, is a well-documented example of a stabilized and extended pidgin. Over the course of around a century, it has become structurally elaborated, with a firm distinction between intransitive and transitive verbs, marked by an ending *-im* (e.g., *masket i pairap* 'the gun went off' versus *man i pairapim masket* 'the man fired the gun'). It also has incipient auxiliary verbs (e.g., *yu mas go* 'you must go,' *yu save smok?* 'Are you accustomed to smoke, do you smoke?'), and markers are available for pastness, futurity and plurality, though these are not obligatory (e.g., *mi bin go* 'I went,' *bai mi go* 'I shall go,' *ol meri* 'the women'). There are even simple relative clause structures (e.g., *Dispela man i slip, em i papa bilong mi* 'The man who is asleep is my father,' *Dok yu paitim asde i gat sik* 'The dog you hit yesterday is ill'), and also simple complement structures (e.g., *Mi kam long helpim pren bilong mi* 'I came to help my friend').

But Tok Pisin is not such an exceptional case as is sometimes claimed. There is increasing evidence that numerous other pidgins were more stable and extended than previously thought. Indeed, it has been claimed that 'many New World creoles were predominantly nonnative languages throughout the entire slave-trade period' (Goodman 1985: 119). In short, pidgins may become stable, relatively homogeneous and fairly elaborate, at a time when they are spoken only by people using them as a second language, without the aid of native speakers.

The elaborated constructions found in extended pidgins arise largely out of the processes, which have already been mentioned. Reanalysis may be particularly important, a process in which an existing form or sequence is reinterpreted. Re-analyses typically involve the demotion or 'grammaticalization' of a full, content word to one of subsidiary status. The demotion of English *belong* to the status of a

preposition *bilong* 'of,' as in *mama bilong mi* 'my mother' happened early in the history of Tok Pisin. Another long established re-analysis involved Tok Pisin *save* 'know' which developed an additional meaning, 'be accustomed to,' and came to be regarded as an incipient auxiliary verb. The reinterpretation probably occurred in ambiguous contexts, such as *mi save kukim kaukau*, in which 'I know how to cook sweet potatoes' came to be 'I am skilled at cooking sweet potatoes' and finally 'I am accustomed to cook sweet potatoes.'

The role of the substrate language is also important. Prominent features in the substrate may be directly translated by a near equivalent in the superstrate. For example, the so-called Tok Pisin 'predicate marker,' a meaningless *i* inserted before the verb, as in *man i am* 'the man came' is possibly due to the identification of English *he* with a 'subject-referencing pronoun' which is obligatory in the Oceanic substrate languages (Keesing 1988).

Increasingly, convergence or 'developmental conspiracies' (Mühlhäusler 1997) are recognized to be an important factor. This is when an element in the superstrate language happens to coincide with one in the substrate (as in the example above), especially when these elements appear to fulfill a communicational need. To take another example, the suffix *him* or *um* was possibly sporadically and unsystematically attached to verbs by Europeans in their 'foreigner talk,' as in some examples of nineteenth century Australian 'jargon' quoted by Hugo Schuchardt (1980: 19): *me like him grog* 'I like wine,' *me no look him* 'I didn't see him,' *him fight him my finger* 'it (pin) pricked my finger.' This *him*, found also in early samples of Melanesian pidgin, was interpreted by speakers of Oceanic languages as equivalent to their own transitive suffix, and *-im* became firmly established in Tok Pisin as a transitive suffix. Similar convergence allowed Tok Pisin to develop primitive relative clauses (examples above), even though embedding is not usually found in pidgins: arguably, surface similarities between English relative clauses and Oceanic ones caused their creation, even though at a deeper level the languages are profoundly dissimilar (Keesing 1988). In short, when there is apparent agreement between structural features of substrate languages and an intermittently occurring feature in the superstrate, this is likely to be assigned a firm function, especially if it seems to be needed in human interaction.

Sometimes, constructions emerge which are in the substrate languages but not in the superstrate. For example, Tok Pisin has a distinction between *we* inclusive (*yumi*, as in *yumi mas painim pik* 'You who are here and I must look for the pig') and *we* exclusive (*mipela*, as in *mipela mas painim pik* 'I and others not here must look for the pig'). This distinction is widely found in the native languages of the region, but is foreign to English. Examples such as these have suggested to some people that pidgins are relexified substrate languages, that is, that they consist of the grammar of a substrate language translated into the lexical items of the base. However, this extreme view does not take into consideration the surprising similarities, which exist between different pidgins—even though the influence of the substrate varies from pidgin to pidgin, and may be more extensive in some cases than in others.

There are possibly two reasons why existing pidgins are so similar. First, a restricted system must by its nature depend on word order to express major syntactic relations (such as those between subject, object, and verb). Consequently, there are only a limited number of options available, and a limited number of permutations of these. The chance that several pidgins will choose the same route is not only highly likely, it is probably inevitable. Each choice will entail further consequences, which will heighten the similarities. For example, topicalization, the fronting of an important topic, might make the consistent marking of transitive verbs more probable, in order to make subjects and objects easier to identify. A preference for topicalization is also likely to affect question words, which will probably be brought to the front, and so on. A second reason why pidgins are similar is that human life the world over is likely to find certain concepts useful in language, such as the distinction between a repeated action and a single one. Such distinctions will tend to emerge independently in different pidgins, especially if they are already marked in the substrate or superstrate.

In conclusion, pidgins can, and often do, become stable and elaborated. Consequently, the move from a pidgin to a creole may be less abrupt and less traumatic than is sometimes suggested. Non-native speakers supplement an early pidgin, and provide a firm base on which creole speakers continue to build.

5. Creolization

A common assumption is that a creole represents a dramatic event, the sudden creation of a language from a rudimentary jargon. Yet such a happening may be a rare phenomenon. (It has been found among deaf signers in Nicaragua (Kegl 1997)). An infant may acquire the creole as a first language from parents who have no common language, but in most cases this infant learns the language of one or both his/her parents alongside, or soon after the creole. Only occasionally will the unfortunate child be a linguistic orphan faced with a minimal system which must immediately be emended—and even then, the emendation cannot take place until s/he is part of a stable peer group.

According to Bickerton in his widely discussed book *Roots of Language* (1981), a first generation creole speaker is inevitably faced with a primitive

hotchpotch. At this point, the infant brings a linguistic 'bioprogram' into play, in which certain distinctions are bound to surface, such as a primitive tense-mood-aspect system involving anteriority versus nonanteriority (*she was ill/she is ill*), punctual versus nonpunctual (*he fought/he was fighting*), irrealis versus realis (*they will go/they are going*) (Bickerton 1981, 1984). Bickerton argues that these distinctions also emerge early in normal child language acquisition, which provides further evidence for the existence of a 'bioprogram.' However, the Bickertonian scenario does not seem to be supported by the evidence, though he deserves considerable credit for the large amount of valuable research, which has been stimulated by his ideas.

There are three major problems with Bickerton's bioprogram approach, over and above the fact that his narrow definition of a creole excludes a wide range of material. First, many features identified as part of the bioprogram were possibly already in existence in any preceding pidgin, as discussed above. Second, the parallels between child language and creoles are largely unsupported (Aitchison 1983). The bioprogram notion supposes that the same distinctions automatically surface in both. However, findings which superficially supported some of Bickerton's claims turned out to be a mirage: the clear-cut distinctions reported by some early workers on child language may have been an artifact of poor experimental methods, and in reality the situation is far from straightforward.

A third problem with the bioprogram hypothesis is that there is a lack of uniformity among creoles, in that several fail to fit in with the predicted bioprogram. Bickerton has suggested that such exceptions may be due to their relative nearness to the superstrate language, unlike radical creoles, which are furthest from the superstrate, and nearest to the bioprogram. But degree of radicalness turns out to be impossible to assess.

In short, Bickerton's bioprogram is more a measure of statistical probability than absolute necessity. The bioprogram hypothesis is not sustainable, but it nevertheless encapsulates probable similarities between creoles.

Some of the reasons for the similarities have already mean mentioned under pidginization. One is the limited potentiality of a pidgin. There are relatively few routes along which it can develop, so similar phenomena are bound to emerge. Another is the recurring need of humans to express certain distinctions, such as one versus more than one. A third, less obvious factor is typological consistency. Languages seem to have a need for internal consistency—though the governing factors underlying it are controversial. For example, any VO system (one in which objects follow verbs as in *chase the pig*) is likely in the long run to develop

prepositions, and auxiliaries which precede verbs. Universal implicational principles of this type are probably of more importance than any simple contrast (e.g., punctuality versus nonpunctuality) which might emerge. Although the notion that creole speakers suddenly invent a new language seems not to be borne out in most cases, there are differences between pidgin speakers and creole speakers, which have profound repercussions on the language, even though the effects may not be as immediate as is sometimes supposed.

First, creole speakers talk much faster than pidgin speakers do. Consequently, frequently occurring items get reduced phonologically. Tok Pisin creole speakers reduce *save* 'be accustomed to' to *sa, long* 'to' to *lo, bilong* 'of' to *blo*, and the 'predicate marker' *i* is not always audible, particularly after high vowels. This speed and phonological reduction can have a significant effect on the grammar. For example, in some contexts the predicate marker *i* has disappeared, in some others it is regarded as part of a following lexical item.

Second, the lexical resources of the language are increased, both by new word formations, and by borrowing. Concepts, which in the pidgin had to be expressed by periphrases, are lexicalized. In Tok Pisin, a phrase such as *man bilong pait* 'an aggressive man, a man given to fighting' becomes *paitman*, and *bun bilong baksait* 'backbone' becomes *bakbun*. The vocabulary has been supplemented by numerous borrowings from English, such as *football, sandwiches.*

Third, there is a tendency for optional elements to be used redundantly, and then to become categorical, or near categorical. In pidgin Tok Pisin *bin* is an optional past tense marker, used primarily when pastness is not clear from the context. In the first generation of creole speakers it is used frequently and seemingly unnecessarily (e.g., *mi bin sik, mi no bin go lo skul* 'I was ill, I didn't go to school'). However, total regularization is unlikely to happen within a generation.

Fourth, there is elimination of unnecessary variety. Pidgins tend to have a number of incipient methods of expressing common functions, which may overlap e.g., pidgin Tok Pisin has a preverbal habituality marker *save* (*pikinini i save krai* 'The child habitually cries'), alongside a postverbal durativity marker (*pikinini i krai i go* 'The child keeps on crying'). Among some creole speakers, the postverbal markers are rarely used, and the distinction between habituality and durativity is disappearing, with preverbal *sa* (from *save*) used for both.

Fifth, simple sentences tend to be conflated and amalgamated, resulting in the continuing development of complex sentence structures. In pidgin Tok Pisin, the word *olsem* 'thus' is used to introduce direct speech (e.g., *Meri i tok olsem: 'Yumi mas kisim pis'* 'The woman said: "We must get the fish"'). In

the creole, *olsem* is clearly equivalent to the English complementizer *that: Yu no save olsem em i sik?* 'Don't you know that he is ill?'

Gradually, the resources of the language become greater, though a creole does not overnight become a perfectly neat system: the tidying up might last over several generations, and can even be partially counteracted by a profusion of new formations, and the effects of phonological reduction. But overall, creolization makes a language-system richer, more efficient, and more streamlined. After several generations, it will possibly be indistinguishable from any other 'full' language.

6. Decreolization

When a creole is spoken in the same geographical area as its original base, there is a tendency for it to be replaced by this more prestigious superstrate, a phenomenon known as 'decreolization.' This is a messy process, involving a range of speakers whose dialect could be a fairly extreme creole, known as the 'basilect,' a middle variety, the 'mesolect,' or the 'acrolects,' a variety of the creole fairly like its (superstratal) base. There is also some overlap between creolization and decreolization, so that it is sometimes unclear which process is under way. For example, superstrate lexical items tend to replace the creole forms in decreolization, yet this also happens in creolization, where intensive borrowing increases the vocabulary stock. Pidgin Tok Pisin has a phrase *bilong wanem* 'because,' which in the creole is often replaced by *bikos*, though this might be interpreted by some as decreolization. However, genuine decreolization can be identified when creole speakers forget the function of creole forms, as when one creole Tok Pisin speaker appeared to have forgotten the meaning of *sa* 'be accustomed to,' because in addition to its normal use to mark habitual actions, she also used it for once-only events in the past (e.g., *Ol sa karim mi lo haus sik* 'They carried me to the hospital'). Increasingly, distinctions found in the creole, but not the base, disappear, and more and more forms found in the superstrate get imported into the creole. For example, decreolized speakers of Tok Pisin use far more examples of English plural *-s* than do genuine creole speakers, for whom it is limited to a small subset of lexical items.

From the point of view of change, the situation is no different from any other type of language contact situation in which extensive borrowing occurs.

7. Conclusion

Structurally, pidgins cannot be neatly separated from creoles, and pidginization, creolization, and decreolization all overlap. They utilize processes found in ordinary language change, especially reduction, simplification, overgeneralization, and reanalysis. They differ mainly in the proportions in which the processes are applied, with more reduction in pidginization, and more reanalysis in creolization.

As in ordinary change, language proceeds by sprouting out multiple options—though these are all possibilities inherent in the system or the surrounding languages. Nothing develops out of nothing. These options are in competition. Eventually one is likely to win out, and the others gradually fade away.

Convergence is often the key to understanding change, both in pidgins and creoles, and in 'full' languages. When substrate and superstrate superficially agree, a firm construction is likely to emerge, especially if this ties in with human communicational needs. In addition, languages need to be internally consistent, in that certain constructions tend to be reinforced within a particular language type, whereas inconsistent ones gradually fade away.

In short, phenomena due to language contact and inbuilt principles are intertwined in an inextricable mix, as in all language change. But pidgins and creoles provide an especially valuable workshop for the study of change because of the relatively increased speed and greater number of alterations, or in the words of the nineteenth century scholar Addison van Name (see *Van Name, Addison*), they exhibit 'greater violence of the forces' (van Name 1869–70: 123).

Pidgins and Creoles: Morphology

F. C. V. Jones

Pidgins and creoles are essentially analytic languages in which the structure of words is morphologically simple. This is because inflectional and derivational affixes from the parent languages are the first casualties of the pidginization process and the last to redevelop. Syntactic features like tense, aspect, and plurality, for example, which are expressed by affixes in many languages, are signaled by separate morphemes in these languages. The morphological formatives which do develop are usually suffixal, or, in a few cases, prefixal additions to the root, and do not involve suppletion (irregular morphological forms like *go-went*) or vowel mutation of the *foot > feet* type.

The growth of morphology in pidgins and creoles is consistent with the phases of development of these languages. These phases are: the jargon or prepidgin, the stabilization, the expanded or extended pidgin, the creolization, and the postpidgin or postcreole.

Most of the information on the growth of morphology during the earlier phases especially comes from accounts of Pacific pidgins, which have been particularly well-studied from their earliest phases of development.

1. The Jargon Phase

During this phase (see *Jargons*), when a pidgin is being born, morphological formatives in words from the parent languages are generally dropped. The few that remain are forms in which the root and its affix have been fossilized or frozen, with morpheme boundaries disappearing, making the word monomorphemic. They are usually adoptions of frequently heard (plural or past tense) forms from the source languages. In some French-related pidgins (and creoles), for example, the final sound of the plural definite article (pronounced /lez/ before a noun beginning with a vowel, but /le/ elsewhere) is attached to the pidgin noun to form a single morpheme that can be either singular or plural in denotation; for example, *zie* 'eye' from the French plural *les yeux* /lezyo/ instead of the singular *oeil*. English-related pidgins (and creoles) have items like *sus* < 'shoes,' meaning 'one or more shoes.' The main reasons for the dropping of affixes is that morphological formatives are a marked or complex category, and their presence would militate against the learning of the emergent, fledgling languages.

In the absence of morphology, there is very little established grammar (time references, for example, are expressed by the use of time adverbials), and there is the widespread use of word-class multifunctionality, with one form being used, for example, as a noun, a verb, an adjective, and an adverb.

2. The Stabilization Phase

It is during this phase that some morphology can begin to emerge, as the pidgin is now developmentally ready for it. However, since the pidgin is still at an early stage of development, very little morphology does occur, while word-order conventions tend to become firmly established. Unmarked or less marked

(i.e., more commonly occurring or simpler) features begin to emerge before marked or more marked (rarer or more complex) features, and the universal principle that derivational morphology precedes inflectional morphology also applies. Developments are internally motivated, showing reanalysis in the grammatical development of the pidgin as it progresses toward the achievement of autonomy as a system.

Morphology can develop to mark word (sub)classes, after considerable variation over time and space, and in sentence position. This seems to be a distinguishing feature of many Pacific pidgins. For example, *-pela* (derived from English 'fellow') is suffixed to monosyllabic adjectives when they are used attributively. Also, transitive verbs are marked by the suffixing of *-(a/i/u)m* or *-it*. In pidgins in general, gender and diminutive distinctions in nouns, though not in pronouns, may begin to develop. A word meaning 'man,' 'woman,' or 'child' is preposed (or in a few cases postponed) to the noun. Also universal during this phase is the use of the word *man* (which in this case is semantically bleached or may simply be regarded as meaning 'human') or its reflex as an agentive suffix to a verb or adjective; for example, (English-related) Tok Pisin: *kamman* (come man) 'new arrival.'

Multifunctionality is even more widespread during this phase, and indeed persists throughtout the lifespan of a pidgin/creole. It also characterizes word-formation devices like compounding and reduplication, which begin to develop (see Sect. 3). Another universal feature in pidgins is the fact that equivalents of wh- question words are bimorphemic compounds expressing units of meaning, rather than monomorphemic words, as is usual in their lexifier languages. Examples are: Kenya Pidgin Swahili, *titu gani*? (thing which?) 'what?'; Cameroon Pidgin English, *wusai*? (which side?) 'where?'

3. The Expanded Pidgin and Creolization Phases

Morphology continues to develop as the autonomy of the language becomes even more firmly established. However, even when it has creolized, the language remains essentially analytic. Morphological (like other linguistic) developments continue to be largely internally motivated, following a clear developmental and markedness hieararchy.

Two universally distinguishing word-formation features which can be particularly clearly seen in English-related pidgins and creoles—compounding and reduplication—assume marked sigificance. Word-level compounds (for example, Tok Pisin *skinwara* [skin water] 'sweat') develop from phrase-level compounds (*wara bilong skin*), which may have originated from lengthier circumlocutions. Such compounds are typically transparent, productive,

endocentric types that may have started their existence as fixed collocations. Many are, however, metaphorical innovations that are used deliberately to increase the lexicon, in response to the growing communicative needs of the growing language. An example is Guinea Bissau (Portuguese related) Creole *piis-kabalu* 'hippopotamus,' from Portuguese *peixe* 'fish' and *cavalo* 'horse.' More abstract patterns, in exocentric compounds, including calques (word-for-word or morpheme-by-morpheme loan translations from substrate languages—the first languages of the pidgin speakers) may also develop. For example, many English-related Atlantic Creoles have *bigeye/bigyai* < 'big eye,' calqued from a West African substratum language, Igbo: *anya uku* (literally 'big eyes') 'covetous (ness).' Some compounds are tautologies designed to reduce the number of homophones in the language, comprising words from the same or from different languages; for example, English-related Trinidadian Creole *go:tkidi* 'kid' (which may have been formed to avoid homophony with *kid* 'child').

Reduplication—the partial or complete doubling (and, in a few cases, triplication) of a word to give a new lexical item—is also mainly an internal development, but is usually accelerated by substrate influence, including straight borrowings. In many pidgins and creoles, in the absence of, or in conjunction with, grammatical words, clitics, and formatives, notions of plurality, accumulation or collectiveness, distribution, and iteration—among others—are frequently expressed by reduplication, which may or may not be a productive process. Examples of reduplication are Nigerian Pidgin English *benben* 'crooked' (from English *bend*); Spanish-related Papiamentu *potopoto* 'muddy' (from substratum language sources).

Some derivational morphology may be borrowed from local vernaculars. Very little inflectional morphology is found in Atlantic pidgins and creoles that are not in their postpidgin or postcreole phase. One example is the use of the suffix *-du* by the Portuguese-related creoles of West Africa (reflecting a conflation of superstrate—lexifier language—and substrate influence) to mark the past participle or to give a verb a passive meaning. In expanded pidgins of the Pacific, inflections have developed from free forms; for example, sentential adverb *baimbai* ('by and by') moving from sentence initial to preverbal or prefix-on-verb position is replaced by *bai*, which functions as the future tense marker *bai*. Morphological causatives have also been achieved, for example, in Tok Pisin, by the suffixation of *im*, first to stative intransitive verbs, next to adjectives, then to non-stative (dynamic) verbs, and finally to transitive verbs.

The application of recursiveness in the development or adoption of affixes, which was severely

restricted in earlier stages of the languages (a word could not contain more than one affix) begins to take place.

These changes continue with creolization and become generalized. Restrictions continue to be relaxed. Creole languages generally evince a hotchpotch of diverse word-formation processes and devices, including many lexicalizations, semiproductive processes, and borrowings, mainly from the superstrate.

4. Postpidgin/Postcreole Phase

This phase is particularly characterized by the borrowing (and possible reinterpretation) of some inflectional and derivational affixes from the (current) superstrate (for example, the English -*s* plural in English-related post-pidgins/creoles). These affixes may be used to express a marked increase in the nonreferential (i.e., stylistic) use of the language; for example, the suffix -*ed* in the Krio word ɛd*yuketɛd* 'educated' gives the word a superlative connotation. Words may even be spontaneously created, based on

superstrate models, as in the case of English-related Bahamian Creole *spokadacious* 'very attractive (of women).'

The proliferation of the borrowing of these formatives helps to increase the complexity of the (post)pidgin/creole, and can even facilitate its depidginization or decreolization. However, the continued borrowing or creation of derivational affixes may eventually lead to a significant decline in multifunctionality and establish a clear morphological patterning that will contribute to promoting the overall naturalness of the language.

Sociolinguistic Area

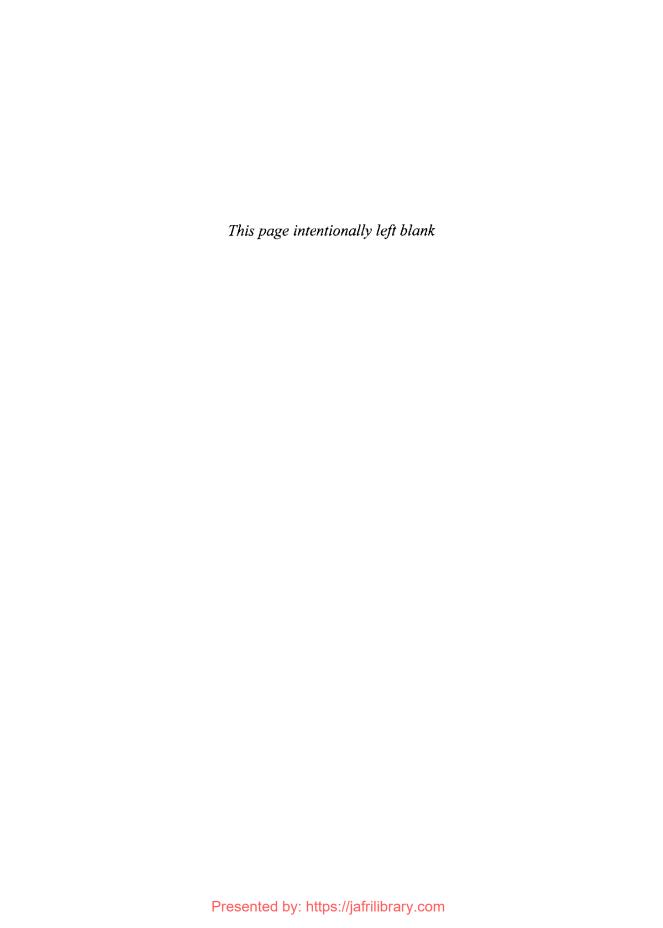
J. D'Souza

A sociolinguistic area is an area in which languages belonging to several different families converge as a result of their daily interaction and because they are called upon to express certain shared social and cultural experiences and adhere to sociocultural norms accepted by members of the society at large. Such an area is marked by widespread bilingualism or multilingualism and by the fact that common social, cultural, and linguistic factors have influenced the languages of the area. A sociolinguistic area, therefore, is characterized by diverse social groups and diverse language families, both of which in the course of time begin to share a grammar of language and a 'grammar of culture.'

The concept of a sociolinguistic area fulfils a critical need as it puts emphasis equally on society and on language, highlighting the significance of each in understanding the other. It provides a new and interesting approach to the study of multilingual areas and sets up new criteria for the study of convergence. The term owes its origins to Emeneau's (see *Emeneau, Murray Barnson*) idea of a linguistic area (1980). His example was of the Indian subcontinent in which languages could be shown to belong to one of four distinct language

families. Yet coexistence for over 2000 years had led to a great deal of structural similarity between the languages (see *Areal Linguistics*). The term 'sociolinguistic area' introduced by Pandit (1972) is meant to indicate that convergence can take place not just structurally, but in terms of sociolinguistic phenomena too.

Sociolinguistic areas are also 'culture areas.' Not all culture areas, however, are sociolinguistic areas. A culture area may be a monolingual area while a sociolinguistic area, by definition, is a bi- or multilingual area in which the shared culture is in part responsible for linguistic convergence. A shared grammar of culture is an important feature of a sociolinguistic area as it provides social motivation for language change and affects linguistic diffusion. The grammar of culture decides the acceptable possibilities of behavior within a given culture area. Included among these are certain uses of language such as expressions of gratitude, terms of address and reference, greetings, farewells, and, in a multilingual society, even the choice of language. As all languages in a sociolinguistic area are affected by a common grammar of culture the possibilities for convergence are increased.

Several areas of the world may be seen as potential sociolinguistic areas primarily on the basis that they are multilingual. To claim that they are indeed sociolinguistic areas one would have to show that the languages of the area have been exposed to common social, cultural, and linguistic forces, have begun to converge, and share a common grammar of culture which acts in consonance with the various languages. One would, therefore, also need to differentiate between convergence phenomena, familial traits, and language universals.


South Asia is a prime example of a sociolinguistic area. Four language families coexist in the region: Austro-Asiatic, Dravidian, Indo-Aryan, and Tibeto-Burman, and bilingualism/multilingualism is widespread. Convergence is a striking characteristic of the area. Despite linguistic and cultural variation the people of the region share a grammar of culture.

Evidence comes from the study of phenomena like diglossia, echo words, explicator compound verbs, onomatopoeics, modernisation, politeness phenomena, and onomastics.

SECTION VI

Language, Power, and Inequality

Critical Language Awareness
J. L. Mey

In pragmatics, the origin of the term 'critical' goes back to an early article which the present author wrote under the title of 'Towards a critical theory of language' (Mey 1979). At about the same time, a group of researchers in England (Roger Fowler and his colleagues at the University of East Anglia; Fowler et al. 1979) developed the notion 'critical linguistics,' in which they put great emphasis on the relationship between social power and language use; they intended to show how the ruling classes of society also determine the ruling language.

In a book I wrote some years later (Mey 1985), I applied my own 'critical' thinking to the problems of social language use, in particular the language of labor disputes and their reflections in the media, and the language used in (or imposed on) second language training for (adult) immigrants. The recurrent themes of that book can be condensed in one brief rule-of-thumb: to find out what language is used for, you have to find the user, and determine what makes him or her speak. The capitalist speaks in a different fashion than does the worker, and this is not so much a matter of the various dialects they use, but of the different ways in which they 'word the world,' as I call it (Mey 1985: 166).

In the late 1980s and early 1990s, with the growing impact of pragmatics on the linguistics and language scene, several further movements arose, professing a critical approach to matters of language use. Institutional discourse, in particular, became a focus of attention not only of people such as Teun van Dijk (in a number of articles and through his influential journal *Discourse and Society*, published since 1990), but also, and mainly, of the so-called Lancaster School of 'critical language awareness' (CLA), centered around Norman Fairclough and his co-workers (1989, 1992, 1995; see *Fairclough, Norman*).

For Fairclough, too, 'critical' has to do with examining the fundamental relations that assign power to various groups in our society; however, he also insists on having language, the 'text,' along, the latter being one particularly important instrument of

exercising that power. In Fairclough's work, the language people speak and write looms large, as it does in the writings of his collaborators and (former) students (Clark, Talbot, Wallace, just to name a few; see the collection edited by Fairclough in 1992). The other aspect, that of power, is emphasized as that which one seizes through discourse; power *is* discourse in a power-oriented society (Fairclough 1992: 50). This means that we read a text in different ways, depending on whether we as readers construe it in a powerful or in a powerless situation.

Even though in the eye of the naive beholder, *power* and its executors may seem the most obvious element of oppression (the SS guard cracking the whip over a line of camp inmates), what characterizes power as a social factor is not its brute force as such but rather, its being accepted as a *natural* thing. 'You can't fight City Hall' is the philosophically resigning expression of such a naturalized relation to the powers that be.

Naturalization is said to happen whenever what should be critically examined and resisted is taken as a 'natural' thing, the self-evidence of the common-sensical world which 'goes without saying because it comes without saying,' to borrow Bourdieu's immortal quip (1977: 167, see *Bourdieu, Pierre*). It is natural for the police to question a prospective detainee, and even if the law tells us that the only information we need to give out are our names and addresses (and perhaps, in certain countries, our social security numbers or equivalents), it is 'natural' for somebody who is pulled over to answer police questions even if they sometimes go far beyond the limits of the morally and legally permissible.

In the following extract (from Fairclough 1995), the legitimacy of the policemen's interventions is never questioned by the detainee, even though they must under every aspect proper to 'normal conversation' (turn-taking, cooperation, and so on) be characterized as 'out of order.'

(*A young woman is brought into a police station in England, having accused three men with rape. A is the woman, B and C are police officers.*)

541

C:...so we can confirm...that you've had sex with three men...if it does confirm it...then I would go so far as to say...that you went to that house willingly...there's no struggle...

C:...so what's to stop you...shouting and screaming in the street...when you think you're going to get raped...you're not frightened at all...you walk in there quite blasé you're not frightened at all...

A: I was frightened

C: you weren't...you're showing no signs of emotion

B: you're female and you've probably got a hell of a temper...if you were to go...

A: I haven't got a temper

B: I think if things were up against a wall...I think you'd fight and fight very hard...(1995: 29–30)

The point of this 'conversation' is for the officers to categorize the complainant as a person who has no right to complain about being raped: first, she probably was asking for it; second, if she had been attacked, she would have put up a struggle; and third, since she has a violent temper, she would have been able to fight off her aggressors quite easily. All this is expressed both in innuendoes and direct statements, and no matter what the woman says or tries to deny, the policemen do not budge an inch from their preconceived notions about what has happened; they are not going to take this case seriously.

The naturalness of this interview in terms of police officer behavior and client response is attested by the fact that at no point during the interrogation is the legitimacy of the police's interventions questioned, not even when they flatly accuse the woman of lying, of being hysterical, of making things up, and so on. Again, it is a case of 'You can't fight City Hall' or, for that matter, the Precinct: the harder we try, the more entrapped we get in our own submission and the more vicious the authorities' retributions for what they consider to be impertinent behavior.

It is the task of a CLA to examine the conditions that underlie such naturalized behaviors (which are frequent also in other societal settings; for a medical parallel, cf. Nijhof 1998). As Fairclough remarks, 'naturalization gives to particular ideological representations the status of *common sense*, and thereby makes them...no longer visible as ideologies' (1995: 42; my italics; the expression 'common sense' is borrowed from the work of Gramsci; see *Gramsci, Antonio*). The ideology of the police as powerful friends of the population ('your friendly local police') masks the reality of police oppression by naturalizing and 'familiarizing' it. When asking for the conditions implicitly determining this situation, we must resort to an analysis of the political power that drives the ideology.

The social aspects of pragmatics are many, but they all have this in common: they deal with the question of 'whose language' we are speaking, and on whose authority we can form our words and utter our sentences. What is important in CLA is to understand the social functioning of our language, not as a matter of linguistic variation, to be described in purely theoretical terms, not as a sociological variable denoting class or other societal parameters. The main impact of pragmatics as a 'social science' is in the way it can help us recognise and fight social discrimination, using instruments such as CLA.

Critical Sociolinguistics

G. Kress

Sociolinguistics is an enterprise developed as a response to certain problems of mainstream linguistics, by and large the nagging worry that language is too obviously imbedded and involved in social practices to sustain the fiction of language as an autonomous object, and of the possibility of

linguistics as an autonomous discipline. Any attempt, however, to situate particular linguistic forms or practices in a social context immediately has critical potential. Taking some criterial examples in the early history of sociolinguistics will show this clearly. Asking a question about code switching (Blom and Gumperz 1972) (see *Code-switching: Overview*) implies questions about a social structure marked by differences of access and by differences of power. To ask questions about the differential uses of micro-level phonetic features (Labov 1972) is to point not only to a class-segmented society, but also to the different social histories of speakers, and to their consequent differential standing in a 'language community' (see *Class and Language*). Included here should be socially important work on language use in courtrooms in professional–client interactions (see *Doctor–Patient Language*), in classrooms (see *Spoken Language in the Classroom*), and other work of a similar kind.

Generally speaking, while this enterprise created opportunities for quite fundamental critiques of society, such critiques were not developed. Linguistic inequality is described, but no particular socially critical point is developed; or, to be more precise, the public ideology (see *Ideology*) of the social equality of a democratic society means that such situations are treated as malfunctions, as 'noise' in an otherwise sound system: a technical problem with a technical solution. Hence any 'problem' in a doctor–patient interaction can be fixed by giving the doctor a course in interpersonal management skills. A similar situation exists with regard to other forms of socio-linguistics with an inherently critical potential, for instance, conversation analysis (CA; see *Conversation Analysis*), and pragmatics. Conversational analysis focuses on microanalyses, with interactants quite deliberately described outside of any social context (see *Pragmatics and Sociolinguistics*). A certain type of pragmatics deals with the problems of use exported to it from syntactic theories (see *Context*), and deals with these not in terms of specifically socially located questions, but in terms of universalizing rules of use.

Feminist analysis of 'women's language,' so-called, is the striking exception (see *Gender and Language*). While it is generally located in the sociolinguistic paradigm (see *Language in Society: Overview*), it provides explicitly political, critical descriptions of particular forms of language, or of language use (Kramarae et al. 1984, Seidel 1988). In this, it has been able to draw on the political and critical project of feminism, a project aimed at interrupting present structurings of power and at a redistribution of power (see *Power and Language*). As well as description, therefore, feminist analysis and theorizing of language have had as one of their major aims a project of 'reconstruction': to imagine and theorize

possible new forms of language which would correspond to (or possibly even assist in producing) new forms of social practice.

A second broad movement of critical sociolinguistics (CSL) has from the outset had quite explicit political and socially critical aims (see *Politics and Language*). Its various strands are broadly complementary but have different origins and methodologies. All aim to reveal social inequalities produced or supported by particular linguistic forms, processes, and practices. One distinguishing factor which may be helpful in thinking about two emphases of this movement is that one tends to take particular social issues as its focus: racism, sexism, militarization, ethnic discrimination (see *Migrants and Migration*), the portrayal of social/geographic regions in the western media ('the Third World,' 'Africa,' etc.), the nuclear arms issue, and so on (see *Linguistic Imperialism*). Studies in this mode describe the manner in which texts construct particular issues from the point of view of those who have power—whether they are groups within one society, or 'north versus south'—focusing on larger-scale textual structures, characteristic and systematic uses of words, syntax, textual forms, etc. (Chilton 1985, van Dijk 1987, 1991, Mey 1985, Wodak et al. 1990) (see *Representation*). The label for this work commonly used by its practitioners is 'critical discourse analysis' (CDA). Theoretically, linguists in this strand tend to draw on existing work in pragmatics, CA, discourse analysis, and text linguistics, but importantly also on work in the social psychology of text production and reception, and on work in cognition generally.

The other body of work is more interested in the linguistic–ideological constitution of discourse (see *Discourse*), in the ideological characteristics and effects of grammatical forms and syntactic structures and processes. In other words, it focuses on the materiality of language itself as politically, socially, culturally, and therefore ideologically constituted (see *Ideology*). It treats all of language as the product of social processes, so that its critical movement is to attempt to reveal the ideological, social constructedness of all linguistic form in order to show and thus open to critique the operations of power in and through language (see *Power and Language*). It too takes texts as the relevant units of analysis. Its practitioners commonly use the labels 'critical linguistics' or 'critical discourse analysis' (where CDA is taken to be a development of, and to include, work in critical linguistics) to describe their work (see Fowler 1991, Fowler et al. 1979, Fairclough 1989, 1992, Hodge and Kress 1979, Kress 1989, 1991, Kress and Hodge 1989).

Theoretically, the antecedents of critical linguistics are both from linguistics—systemic linguistics predominantly (Halliday 1978, 1985); with certain uses of realist interpretations of an *Aspects*-type

transformational grammar (Chomsky 1965); as well as the important influence of the work of Basil Bernstein on codes (Bernstein 1968, 1990, see *Code, Sociolinguistic*); and from sociological, political, and philosophical theories, and the work of Freud and Marx (see *Marxist Theories of Language*).

One significant difference between the latter and the former kinds of CDA lies in the fact that critical linguistics had always seen it as one part of its projects to reform and reconstitute mainstream linguistics, to make it more responsive to social considerations, and to shift it from its definition as an autonomous discipline to a definition which saw linguistics as a socially responsible and responsive discipline. This aim may be considered to have been a failure; nevertheless, there are significant signs of change. One is the sheer number of linguists working in a framework of overtly critical sociolinguistics, of whatever kind. Another is the growing strength of CDA, and of the practitioners happy to work (together) under that label.

Critical discourse analysis (as a cover term for all of this kind of CSL) is positively multi- and interdisciplinary: this reflects the fact that CDA sees the domain of its application as other than that of linguistics; and certainly not autonomous in any sense. It is in the process of defining its domain; and this implies necessarily, that it is in the process of defining its theoretical constitution. Previously, all of CSL had been willing to take categories and (descriptive) methodologies from existing linguistic theories. This is in the longer run an unsatisfactory situation, as theoretical categories cannot simply be transported from one theoretical framework to an entirely different—perhaps even ideologically hostile—one. The problems of mainstream linguistics, from the point of view of CSL and particularly of CDA, are numerous, and these will need to be addressed in a new theory of language. There follows a list of these problems from the point of view of CSL/CDA:

(a) Mainstream linguistics (ML) is ahistorical; CSL needs a theory which is fully historical, at a micro- and macro-level. Without history, linguistic theory cannot account for linguistic change, and in particular it cannot account for changes in particular directions which correspond to the arrangement of forces in society. CSL needs a theory which is equally attentive to the micro-level histories of conversations, interviews, writings, and readings of written texts, and can connect these with each other and to the macro-histories of cultural groups and of society as a whole.

(b) ML is autonomous; CSL, as its name declares, needs a theory which is fully social. The move from an autonomous conception will allow social categories to become the categories which are productive (generative) of linguistic form, at all levels, from morpheme to textual structures.

(c) ML has no theory of the individual language user as a socially and historically formed subject, with particular social histories, and operating in specific social positions, hence always in structurings of power. In a recast theory, the individual language user will be seen as active and agentive, as the bearer of social structures and therefore of differential power in relation to the production of texts, and, consequently in relation to linguistic change. It is through the actions of socially formed language users that the contradictory forces of linguistic convergence and difference can be explained in the production of a hegemonic structure socially and linguistically (see *Hegemony*).

(d) ML is a gendered discipline, as a consequence of (a), (b), and (c); it is also blind to its formation in relation to class (see *Class and Language*), and to very many other fundamental social categories (see *Social Class*). In a socially founded theory, gender along with other fundamental social categories will form one of the set of productive (generative) categories, and will therefore enter from the beginning into analyses and descriptions.

(e) ML is a sentence- or clause-based discipline; CSL and CDA are text-based. Text is a crucial unit in that, as the site of realization and production of meaning, it is the site of contestation of the meaning systems of the producers of the text, in a field of power difference which bears on the outcome, that is, on the text that is produced.

(f) ML is a formalistic discipline. To use Saussurean notions, it is a discipline which has focused on the signifier (form) to the exclusion of the signified (meaning). CLS and CDA need a notion of the sign, not as an arbitrary conjunct of signifier and signified (see *Saussurean Tradition and Sociolinguistics*), but as a socially, ideologically motivated structure. The motivation itself derives from the 'interest' if the producer(s) of the sign, that is, their social histories and present social locations.

(g) ML is a monologic, producer-based theory. CSL needs a heteroglossic account, and a communicative one, that is based equally on hearer/readers and speaker/writers. The facts of contemporary multicultural societies make heteroglossic accounts essential, although all societies are likely to be heteroglossic due to significant differences based on class, profession, and region, for instance.

It is clear that CSL is at a crucial stage in its development. It cannot continue to draw eclectically

on sets of categories from theories which were constructed for entirely different purposes, and with quite different political motivations. For one thing, to do so actually not only imports theoretical/ideological problems into CSL, but it also reinforces existing theories by leaving them unchallenged, as both appropriate for and accurate in *their* domain. The initial project of CSL is in a real sense accomplished; the new project is quite clearly a much more far-reaching one, namely to construct the theory implied by and necessary for the ongoing range of activities. This theory, a new conceptualization of language, can then as a theory of language act as a challenge to those social structures being dealt with in the early 2000s by an essentially inappropriate analytic and descriptive methodology.

In its new form, it will of course cease to be CSL, the dichotomy of linguistics and sociolinguistics, critical and uncritical theories having been superseded. The new linguistic theory will need to reflect on its own place, on the place of language in the total assembly of modes of communication, and become reflexive and critical of its own position.

Discrimination and Minority Languages

T. Skutnabb-Kangas and R. Phillipson

People can be discriminated against on the grounds of their gender, class, race, or language. The reality of such discrimination, and the urge to combat the injustice of it, has inspired many human rights covenants and some national legislation.

Language can itself also be discriminatory in several ways, or it can be used in discriminatory ways. The 'form' of the language itself, its vocabulary (or lack of vocabulary in areas of importance to dominated groups) and connotations, can be racist

545

('nigger') or ethnocentric ('developing' country), sexist (see *Gender and Language*), classist, ageist, militaristic, nationalistic, etc. Words can make some groups of people or their characteristics invisible (the rights of 'Man'), or appendices to others ('lady doctor,' 'male nurse'), or stereotype them negatively ('Third' World). Language can also be *used* in discriminatory ways, so that some groups become invisible ('the anglophone countries of Africa' ignores the fact that the vast majority of the population in such countries have no command of, or do not habitually use, English). Several professional associations and publishing houses have issued codes of linguistic conduct, which instruct authors how to avoid such discriminatory language.

Individuals and groups can also be discriminated against on the basis of language: how they speak (class background, gender, geographic origin, etc.) or which language(s) they speak (or do not speak). Judgments of class background or mother tongue or gender made on purportedly linguistic evidence lead to attributions of competence and moral qualities as well as to the creation of esthetic norms and feelings of solidarity, as social psychological studies have shown. The class bias of the 'standard' language that schools inculcate has a major influence on school achievement and discriminates against many children. The present article concentrates on the kinds of discrimination that speakers of dominated/minority languages, indigenous, national, regional, or immigrant, encounter because of their mother tongue(s) (see also *Minority Languages*).

1. Linguistic Rights and Human Rights

Many minority groups were granted specific protection in the treaties signed at the end of the First World War. Since 1946, the United Nations has had a Sub-Commission on Prevention of Discrimination and Protection of Minorities; interestingly, it has recently been renamed and is now called Sub-Commission on the Promotion and Protection of Human Rights. Within the UN framework, a series of human rights covenants have been devised, signed, and ratified. These attempt to provide minorities with at least some of those human rights (hereafter HRs) that majority/dominant populations often take for granted, including linguistic human rights (hereafter LHRs). Article 27 of the International Covenant on Civil and Political Rights (1966) still contains the most far-reaching binding protection for LHRs for minority languages. It declares:

In those States in which ethnic, religious, or linguistic minorities exist, persons belonging to such minorities shall not be denied the right, in community with the other members of their group, to enjoy their own culture, to profess and practice their own religion, or to use their own language.

A major survey was conducted for the UN (Capotorti 1979) to analyze juridical and conceptual aspects of protection against discrimination and to solicit information from governments worldwide so as to assess how minorities are treated *de jure* and *de facto*. Immigrant minorities were explicitly excluded from consideration, 'because of their voluntary assimilation' (Capotorti 1979: 10), or because they were not to be encouraged to 'form within that State separate communities which might impair its national unity or its security': they 'could not be regarded as minorities as this would endanger the national integrity of the receiving States' (Capotorti 1979: 33). These fears reflect a monolingual norm (see below). They are still one of the main reasons why states are so reluctant to guarantee proper protection to minority languages and their speakers. Still, the fears seem to be largely unfounded (see Joshua Fishman's comparative study of correlations between number of languages in a country, economic prosperity, social strife, and many other variables; Fishman 1989, see also Eide 1995.) Often it is precisely the lack of LHRs that causes conflicts that can then be labeled 'ethnic.' The Capotorti report concluded that most minorities, not least linguistic ones, were in need of much more substantial protection. It stressed the key role of education through the medium of the mother tongue for linguistic and cultural maintenance and vitality. It also interpreted article 27 as imposing an obligation on states to actively promote minority languages. This presupposes that states provide adequate financial support for these languages. The UN Human Rights Committee interpreted in a General Comment (6 April 1994) Art. 27 as protecting all individuals on the state's territory or under its jurisdiction (i.e., also immigrants and refugees), irrespective of whether they belong to the minorities specified in the article or not. The General Comment also stated that the existence of a minority does not depend on a decision by the state but requires to be established by objective criteria. It recognized the existence of a 'right,' and imposed positive obligations on the states.

There is however abundant evidence of groups and an individual being deprived of their LHRs. Often language shift occurs as a result (see *Linguicide*). Many international covenants beginning with the UN Charter, declare that discrimination should be outlawed but do not in their binding articles oblige states to promote minority languages. Many states in fact expect their indigenous and immigrant minorities to assimilate to the dominant culture and language.

2. Action Against Linguistic Discrimination

Using the HRs system might be one way forward in protecting diversities in a globalized 'free market' world. Instead of granting market forces free range,

HRs, especially economic and social rights are, according to human rights lawyer Katarina Tomaševski (1996: 104), to act as correctives to the free market. The first international HRs treaty abolished slavery. Prohibiting slavery implied that people were not supposed to be treated as market commodities. ILO (The International Labour Organisation) has added that labor should not be treated as a commodity. But price tags are to be removed from other areas too. Tomaševski states (1996: 104) that 'the purpose of international HRs law is ... to overrule the law of supply and demand and remove price-tags from people and from necessities for their survival.' These necessities for survival include not only basic food and housing (which would come under economic and social rights), but also basics for the sustenance of a dignified life, including basic civil, political and cultural rights, including LHRs.

The international HRs regime started to develop in a prominent way directly after the Second World War under the auspices of the United Nations. Most of the initial rights were individual rights. This resulted in non-development for most of those rights, which during the League of Nations had included some language rights, namely, minority rights (which are necessarily collective). One of the arguments was that if every individual had certain rights, people were protected as individuals, and collective rights were not needed. Today, certain collective rights are increasingly being included in the HRs regime.

Awareness of linguistic discrimination has led, inter alia, to the Council of Europe elaborating a 'European Charter for Regional or Minority Languages' and a 'Framework Convention for the Protection of National Minorities' (both in force since 1999). But international and regional (African, American, and European) binding Covenants, Conventions, and Charters give very little support to LHRs in education, and language is given a much poorer treatment than other central human characteristics. Often language is present in the lofty non-duty-inducing phrases in the preambles of the HRs instruments, but disappears completely in educational parts. When it is there, the Articles dealing with education, especially the right to mother tongue medium education, are more vague and/or contain many more opt-outs and modifications than any other Articles, as has been shown in many books and articles (see the bibliography). At the most, languages have negative rights (non-discrimination prescriptions) rather than positive rights where the clauses or articles about them would create obligations and contain demanding formulations and where the states would be firm dutyholders and be obliged to ('shall') act in order to ensure the specified rights. A couple of illustrations of each type follow the ones where language disappears, and the ones with

vague formulations, modifications and opt-outs (see Chapter 7 in Skutnabb-Kangas 2000 for a fuller treatment).

Language disappears completely in the *Universal Declaration of Human Rights* (1948) where the paragraph on education (26) does not refer to language at all. Similarly, the *International Covenant on Economic, Social and Cultural Rights* (adopted in 1966 and in force since 1976), having mentioned language on a par with race, color, sex, religion, etc. in its general Article (2.2), does explicitly refer to 'racial, ethnic, or religious groups' in its educational Article (13). However, it omits reference to language or linguistic groups.

In the *UN Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities*, adopted by the General Assembly in December 1992, most of the Articles use the obligating formulation 'shall' and have few let-out modifications or alternatives—except where linguistic rights in education are concerned. Compare the unconditional formulation in Articles 1.1 and 1.2 about identity with the education Article 4.3 (emphases added, '*obligating*' in italics, '**opt-outs**' in bold):

1.1. States *shall protect* the existence and the national or ethnic, cultural, religious and linguistic identity of minorities within their respective territories, and *shall encourage* conditions for the *promotion* of that identity.

1.2. States *shall* adopt **appropriate** legislative *and other* measures *to achieve those ends*.

4.3. States **should** take **appropriate** measures so that, **wherever possible**, persons belonging to minorities have **adequate** opportunities to learn their mother tongue **or** to have instruction in their mother tongue.

The questions one can ask are what constitutes 'appropriate measures,' or 'adequate opportunities,' and who is to decide what is 'possible'? Does 'instruction in their mother tongue' mean through the medium of the mother tongue or does it only mean instruction in the mother tongue as a subject? The opt-outs and alternatives permit a reluctant state to meet the requirements in a minimalist way, which it can legitimate by claiming that a provision was not 'possible' or 'appropriate,' or that numbers were not 'sufficient' or did not 'justify' a provision, or that it 'allowed' the minority to organize teaching of their language as a subject, at their own cost.

The Council of Europe *Framework Convention for the Protection of National Minorities* Article covering medium of education is so heavily qualified that the minority is completely at the mercy of the state:

> In areas inhabited by persons belonging to national minorities traditionally or in **substantial** numbers, **if**

547

there is sufficient demand, the parties shall **endeavour** to ensure, **as far as possible** and **within the framework of their education systems**, that persons belonging to those minorities have **adequate** opportunities for being taught in the minority language **or** for receiving instruction in this language (emphases added).

The conclusion is that we are still to see the right to education through the medium of the mother tongue become a human right. There are some examples of what we consider positive recent developments, at least on paper: HRs instruments, draft instruments, recommendations, declarations, or comments. They might give some cautious reason for hope. The impact of the recent positive developments in counteracting linguistic genocide in education and the killing of linguistic diversity has yet to be seen.

Implementation needs to follow. Without implementation, monitoring and proper complaint procedures, much of the potential in the new or emerging instruments will be lost.

A draft *Universal Declaration of Linguistic Rights* was presented to UNESCO in 1996 as a first step towards further elaboration and adoption, but it is unlikely that it will be adopted, even in a revised form. It was, however, the first major international attempt to specify universal linguistic rights. Even in this Declaration, it was clear that educational language rights, in contrast to cultural rights, were not seen as inalienable.

Court action can be a significant way of challenging linguistic discrimination. In the USA, a number of cases have been brought for this purpose. Significant is the case of *Lau vs. Nichols*, in which students of Chinese ancestry claimed that the San Francisco Unified School District failed in its obligation to provide adequate education for them. The US Supreme Court ruled that 'Under these state-imposed standards there is no equality of treatment merely by providing students with the same facilities, textbooks, teachers, and curriculum; for students who do not understand English are effectively foreclosed from any meaningful education' (quoted in Center for Applied Linguistics 1977: 7). Many court cases in the USA have challenged discrimination on the basis of language or dialect in education, hiring practices, and promotion.

A case of central relevance to minority education was brought against the Norwegian State. A Saami (called 'Lapp' in colonial language), Johan Gávppi, who knew no Norwegian when he went to school and whose teachers knew no Saami, got little benefit from school and was illiterate until his own children taught him to read and write. He sued the Norwegian State for damages for failing to give him the basic education he was entitled to under Norwegian law. All Norwegian courts and the European Commission on Human Rights deemed the case obsolete but other

cases may follow. This case has wide symbolic significance. If the principle is established that a minority child is entitled to financial compensation for inappropriate education, then one can envisage indigenous and immigrant minorities worldwide following suit.

The relevant academic arguments were already assembled back in 1953 in an authoritative UNESCO report which considers it 'axiomatic that the best medium for teaching is the mother tongue of the pupil' and that this should be 'extended to as late a stage in education as possible.' This has been confirmed in educational guidelines issued for the OSCE High Commissioner on National Minorities, Max van der Stoel, *The Hague Recommendations Regarding the Education Rights of National Minorities & Explanatory Note* (October 1996). The Hague Recommendations are one of the recent positive developments. In the section on 'Minority education at primary and secondary levels,' mainly mother tongue medium education is recommended at all levels, including bilingual teachers in the dominant language as a second language (Articles 11–13). The Recommendations are an authoritative interpretation of international human rights law (see the special issue on them, *International Journal on Minority and Group Rights. Special Issue on the Education Rights of National Minorities* 4:2, 1996/1997). The education of minorities is still a controversial issue. What also needs stressing is that relatively little research has been conducted by minority group researchers themselves. The structure of the academic world (research financing, careers, dominant paradigms, etc.) militates against minority voices being heard (but see Skutnabb-Kangas 1988).

3. From Sticks to Carrots and Ideas; From Biologically-based Racism to Ethnicism and Linguicism

The means of control over all dominated groups (not just minorities) are progressively shifting from 'sticks' (physical violence) to 'carrots' (negotiation) and 'ideas' (psychological violence). Resisting the power-holders used to lead to physical punishment (an external negative sanction) and later on to shame, a guilty conscience, or a feeling of having chosen wrongly (an internal negative sanction). Submitting leads now to rewards (internal positive sanctions). Rewarding those who submit and making them feel they have made the right choice (by glorifying the dominant language, stigmatizing dominated languages, and making the choice to drop these in favor of the dominant language seem rational), is a less expensive and more efficient way of upholding control than the use of physical violence (armies, police, etc.). Making those who do *not* submit and achieve rewards believe that their own characteristics,

deficiencies, and handicaps are to blame, ensures hegemony in a less risky way than the use of physical force.

An important criterion worldwide for determining which groups obtained less than their fair share of power and resources used to be their so-called 'race.' 'Race' has, for several reasons, become an untenable criterion. It is no longer claimed that certain 'races' are more fit to rule than others are. Biologically based racism as an important ideology of hierarchization has been progressively replaced by ethnicism (Mullard 1988) and linguicism (see *Linguistic Imperialism*, Skutnabb-Kangas 1988), which relate to cultural (rather than biological) characteristics ascribed to various ethnic groups and languages. Instead of superior races, certain ethnic groups (or cultures) and languages are now seen as fitter to rule and expand; others are to adopt their cultures and learn their languages. The characteristics attributed to these cultures and languages relate to modernization, technology, efficiency, development, Western capitalist middle-class market-oriented values, and so on.

Since global market connections and the colonization of the mind of the less powerful require the use of a common language, the smaller languages are marginalized and underdeveloped. Internationally there is a hierarchy with functional differentiation between local languages and a 'world' or 'international' language (and its concomitant culture). Internally in countries which do not boast a 'world' language, local languages are increasingly confined as the traditional languages of the home and hearth, whereas the major languages are used for international instrumental roles in business, administration and politics, and also increasingly in domestic contexts (for instance, as the in-house language in transnational corporations, in higher education, in the media, etc.). These processes underlie the dramatic rise of English as an 'international' language in recent decades (Phillipson 1992, see also *Linguistic Imperialism*).

Discrimination by means of language can be analyzed as a reflection of linguicism. Linguicism is defined as:

> Ideologies, structures and practices which are used to legitimate, effectuate and reproduce an unequal division of power and resources (both material and non-material) between groups which are defined on the basis of language
>
> (Skutnabb-Kangas 1988: 45)

Language is thus in several ways increasingly important as the instrument through which groups with less access to power and resources are controlled.

Proficiency in the colonists' language was vital for social mobility in the colonial period, and this position has generally not changed since independence. For immigrant groups, the dominant group regards proficiency in the official or national language(s) of the country of residence as the vital goal of education. This is so, even when there is plenty of research evidence that educating minority children through the mother tongue would be advantageous for their overall educational, cognitive, psychological, and social development and can lead to high proficiency in the dominant language (Cummins 1996, Skutnabb-Kangas 2000). Linguicism ensures that most resources, in teacher education, curriculum development, and teaching schedules are allocated to the dominant language. An ideology of maximum support for the dominant language and marginalization of other languages accompany these structural measures. The latter tend to be regarded as educational handicaps rather than as resources. Education is inspired, misguidedly, by a monolingual norm. This norm implies at a societal level a belief that 'one state, one nation, one language' is a desirable and inevitable state of affairs, necessary for national unity, modernization, and progress, and that multilingualism leads to national disintegration, backwardness, inefficiency, and poverty. At an individual level monolingualism is seen as normal and healthy, and bi- or multilingualism as a temporary, negative phase on the path from monolingualism in one language (e.g., minority mother tongue) to monolingualism in another language (the majority language). The monolingual norm also implies 'either–or' thinking: either you maintain your minority mother tongue, and that means that you do not learn the majority language properly, or you want to learn the majority language, and therefore you cannot maintain your mother tongue (Skutnabb-Kangas 1996). Education inspired by this monolingual norm is organized subtractively (see Lambert 1975) for minority language speakers: they learn a major language instead of or at the cost of their own, not in addition to it (see *Bilingualism, Societal*). By contrast the foreign language learning of the dominant group is additive, they add more languages to their existing linguistic repertoire, at no cost to their mother tongue. It is subtractive learning of dominant languages that turns these languages into killer languages and threatens the world's linguistic diversity. What is needed for linguistic diversity to be maintained on earth and for discrimination to stop is proper protection of the LHRs of minorities, especially an unconditional right to mother tongue medium education, and additive learning of other languages.

Hegemony

G. Mininni

'Hegemony' (from Greek *hegéomai* 'I lead') is the key word summarizing Antonio Gramsci's (see *Gramsci, Antonio*) original contribution to the working out of a Marxist theory of society. Gramsci's hegemony theory is also an exemplary meeting of Marxism and linguistics, as it emphasizes the close connection between the language question and social organization, a connection marked by the ideological clash and temporary consents to systems of values or hegemonic meanings. The social dialectic between 'consent' and 'dissent' is regulated by the hegemonic function of human groups and of their own ideas. Social uses and the nature of a language itself provide an evident model of this dialectic, as every discursive event is regulated by the synchronous activation of the principles of dialogicity and opposition, cooperation and competition.

1. Hegemony as an 'Apparatus of Spiritual Government'

Forced to wonder about the reasons for the labor movement's defeat in the 1920s—a defeat he personally experienced in the cells of a fascist jail—the leader of the working class in Italy dedicated his life to investigating a subject that Marxism had neglected: the 'spiritual' conditions needed for the socialist revolution to succeed. His early meditations about the Party, which 'works through millions and millions of spiritual connections' as 'an irradiation of prestige,' are generalized in the concept of hegemony; this gradually loses its Leninist connotation of 'proletarian dictatorship' and acquires new nuances which turn out to be more and more connected to an 'ideal,' 'cultural,' 'moral,' and 'linguistic' supremacy. In short, hegemony indicates an 'apparatus of spiritual government' as it points out the ability of a group to lead the whole community to accept them freely as the ruling group. Such an ability belongs to the 'civil society' that wins the spontaneous consent of the masses of a nation to the legitimately expressed power.

2. A Passage from Society to the State

Gramsci inserted the complex dynamics between 'civil society' and 'political society' (or 'state') into the traditional Marxist scheme of dialectic relations between the economic basis and ideological superstructures, thus refining the historical materialist explanation of social control devices. The dominant class within a society takes possession of the state and

the practice of this power is to be seen both as an intellectual as well as a moral management of the kindred groups and as a coercion of the opposing groups. If a class dominates over the whole community through forms of government which are based on coercion mechanisms only, this means that it has lost its hegemonic function. Whenever a detachment between the civil and political societies occurs, the dominant class is no longer ruling. This means that 'a new problem of hegemony has arisen; in other words, the historical basis of the State has shifted.' The notion of hegemony is consistent not only with the tactic of the 'historical block' between workers and peasants to carry out a social revolution in Italy, but also with Gramsci's interpretation of the 'Modern Prince': an authority interiorized in the collective conscience, a freely accepted need, a 'categorical imperative' which directs social behaviors. Hegemony highlights the social superego activation processes. Due to this complex dynamic, the concept of hegemony magnetizes the rather static notions of 'culture' and 'ideology' (Williams 1977), thus showing how the social reproduction of a group is given in the historical reality of uneven relationships, asymmetries in resources, and gaps in competences; a reality that always revises the organic picture of the fight for power. The task of the subordinate class, which is interested in a fairer and freer social order, is to secure the necessary instruments for hegemony in order to realize 'modern democracy,' through its own system of alliances and mediations. These instruments are in the hands of the intellectuals.

3. Hegemony as a Praxis for Intellectuals

As the hegemonic dimension of a class is expressed in its ability to organize the world's experience and to give life a sense, its implementation is mainly attributed to a group (which is often closed into a caste) of persons who are able to plan the whole sphere of the social psyche. The intellectuals can derive a 'spontaneous consent' to the orientation the chief, dominant group gives to social life from the trust and prestige they historically command on the part of large masses of population. The intellectuals' ruling function originates from the 'political' direction they give to their special knowledge and from the 'pedagogic relationship' they set up with the other social forces. The intellectuals decide the hegemonization processes of a class both when they spare no efforts to renovate higher culture (arts, science, philosophy) and when they devote themselves to school organization or to a specific use of mass-communication instruments. It is understood that the intellectual acts as a pole of attraction or as a 'permanent persuader,' mainly thanks to the privileged relationship he is able to epitomize with the group's language.

4. The Linguistic Matrix of Hegemony

Gramsci's conception of hegemony has an evident linguistic matrix (Lo Piparo 1979). It is two-edged: from a historical point of view, the concept of 'linguistic prestige'—derived from his early glottology studies at the school of the neolinguist Matteo Bartoli—acts as a first organizing basis for the idea of hegemony; from an illustrative point of view, this finds evidence of its validity in the nature and function of language. The premises of a Marxist language sociology (the priority of the sociocommunicative function and of the cultural restraints which are historically imposed on its use) are revised by Gramsci's notion of hegemony in such a way that both the communicative needs of a historical community and the dynamics within the systematic organization of a language are safeguarded (Rosiello 1959). As a result, evoking what Vico said, changes in language are connected with the metaphorization process concerning the sense, but this specifically linguistic resource is activated by the tension to hegemony pervading the cultural formation of a group. Not only is the formation of national languages explained as a result of hegemonic relations between dialects and of a larger intellectual and social hegemony, but the social awareness of linguistic problems—from the educational aspects concerning the normativeness of 'immanent grammar' in the system to the social diffusion of poetic styles—reveals the conflicting interests existing within hegemony processes.

> Every time the question of the language appears, in some way or other, this means that some other problems are arising: the formation and growth of the ruling class, the need for establishing closer and safer relationships between ruling groups and the popular, national mass; that is, the need for reorganizing cultural hegemony.
>
> (Gramsci 1971)

The notion of hegemony enables Gramsci to penetrate the dialectic which sees the language both as an expression and a component of the social and political process in a human community.

Honorifics
M. Shibatani

The term 'honorifics' refers to special linguistic forms that are used as signs of deference toward the nominal referents or the addressee. The system of honorifics constitutes an integral component of the politeness dimension of language use, but whereas every language appears to have ways of expressing politeness, only certain languages have well-developed honorifics. Generally speaking, the languages with highly developed honorifics systems are concentrated in Asia—Japanese, Korean, Tibetan, Javanese, and Thai being among the best-known languages of this group. A thorough study of honorifics requires a two-pronged approach. The description of honorifics as grammatical forms is one thing and is relatively easy to arrive at, whereas the description of their actual use requires wider pragmatic as well as sociolinguistic perspectives that take into consideration elements of a conversational situation, such as the relationship between the speaker and the addressee, and the functional role that honorifics play in communicative interaction. While the pragmatic aspects of honorifics usage are gaining increasing attention in the field, the available descriptions are, by and large, purely grammatical with little information on usage. This article endeavors to correct this imbalance by devoting one half to the grammatical aspects of honorifics, and the other half to the pragmatic and sociolinguistic issues, where aspects of Japanese honorifics usage are examined in some detail.

1. Referent Honorifics

'Referent honorifics' are those forms that are used to show deference toward the nominal referents. This type of honorifics is most widespread and the historical development of the honorifics system, as available in the case of Japanese, indicates that this is the most basic form of the honorifics (see *Politeness*).

1.1 Titles

The commonest forms of referent honorifics are honorary titles used together with the name. Many languages have honorary titles similar to the English form *Mr* and the German form *Herr* that derive from the nouns designating higher social roles or divine beings. Also common are titles deriving from the names of occupations or ranks in specific social groups, e.g., a military unit, a business group, and kin-terms that are considered high in social standing; e.g., *doctor, professor, general, uncle, aunt.*

Something similar to the honorary titles are honorific endings observed in Korean, Japanese, and others. The Korean suffix *-s'i* attaches either to the full name of a respected person or just to the family name of a person engaged in a menial labor, whereas the higher-level ending *-nim* attaches to the combination of a family name and a professional title; e.g., *Kim kyoswu-nim* (Kim professor-SUFFIX) 'Professor Kim.' The Japanese ending *-san* and its higher-level counterpart *-sama* attach to family names as well as given names yielding honorified forms; e.g., *Yamada-sama* 'Mr Yamada,' *Masao-san* 'Masao (honorified first name).' These are, in fact, part of the general amelioratory system of reference, which includes other endings such as *-kun* (used for the names of male equals or inferiors) and the diminutive *-tyan* (used typically for children's first names).

1.2 Pronouns

Pronominal forms, especially those referring to the addressee, namely the second-person pronouns, are often the target of honorific elaboration. The best-known example of this case is the use of the plural pronouns, such as the forms for *you* (PL), *they* and *we*, in reference to a singular addressee (or a third-person referent) as a sign of respect; e.g., French *vous*, German *Sie*, Russian *vy*, Tagalog *kayo* 'you.PL,' *sila* 'they,' Turkish *siz* 'you.PL,' Ainu *aoko* 'we.INCL.' Javanese presents one of the most complex prominal systems elaborated along the honorific dimension (see Table 1).

One notable honorific aspect having to do with the second-person pronominal forms is that many languages of Asia, e.g., Japanese, Korean, Dzongkha (Bhutan), simply avoid using the second-person pronominals to a superior out of deference (see Sects. 3 and 5). In these languages, the second-person reference, if the need arises, is made by the use of a professional title, e.g., Japanese *sensei* 'teacher,' Korean *sacangnim* 'company president,' or of kin-terms, e.g., Korean *emeni* 'mother,' or of a combination of a kin term and an honorific ending, e.g., Japanese *ozi-san* 'uncle.'

1.3 Nouns

The honorified nouns express deference either directly toward the referent or indirectly toward the owner, the creator, or the recipient of the referred object. As opposed to the first two categories of the referent honorifics, the number of languages with this system declines sharply.

Both suppletive and regular morphological processes as well as combinations of both are observable. Korean nominal honorific forms *cinji, yonse, songham* supplete *pap* 'meal,' *nai* 'age,' *irum* 'name,'

Table 1. Javanese personal pronominal forms (adapted from Sakiyama 1989).

	Ordinary	Middle	Honorific	Super-honorific
1st person	*aku* *tak-, dak-* *-ku*	*kulå*	*kulå*	*kawulå* *abdidalem*
2nd person	*kowé* *ko(k)-, -mu*	*(an) dikå*	*sampéyan*	*panjenengan* *nandalem* *sampéyan dalem* *slirå*
3rd person	*dhéwék(n)é* *dhék(n)é* *di-* *-(n)é*	*piyambaké* *kiyambaké*	*piyambakipun* *kiyambakipun* *dipun-* *-ipun*	*panjenenganipun* *-ipun*

respectively. Often suppletive honorific forms are loanwords borrowed from superior cultures. For example, the honorific forms *bida* 'father' and *manda* 'mother' for the native Thai words *po* and *me*, respectively, are from Pali. Likewise, many honorific forms in Javanese are loanwords from Sanskrit and Arabic; e.g., *arta* 'money' (Sanskrit), *kuwatir* 'to fear' (Arabic).

Kin terms in Japanese are made honorific by the suffixation of honorific endings *-sama* or *-san*. Between *o-kaa-sama* 'mother,' and *kaa-san* 'mother,' for example, the first form with the honorific prefix *o-* (see below) and the *-sama* ending is the more elevated form.

Nominal honorific forms typically refer to objects possessed or created by respected persons. The favorite nominal honorific derivation in Japanese is by means of the prefix *o-* or *go-*; e.g., *o-kaban* 'bag,' *go-hon* 'book,' *o-hanasi* 'talk,' *go-koogi* 'lecture.' A combination of suppletion and prefixation is observed in the Japanese form *o-mesimono* for *kimino* 'Japanese-style clothes' or *huku* 'Western-style clothes.'

The all-purpose Japanese nominal honorific prefixes *o-* (for native words) and *go-* (for Sino–Japanese loanwords) have their etymologies in words with meaning associated with greatness (for the native *o-*) and ruling (for the Chinese *go-*). Tibetan nominal honorific prefixes, on the other hand, have a classificatory scheme as their basis (Kitamura 1974). Thus, the honorific form *bdu* for *mgo* 'head' functions as an honorific prefix for objects having to do with the head, upper part, or superior; e.g., *skra* 'hair' → *bdu-skra*, *zhwa-mo* 'hat' → *bdu-zhwa*. Likewise, the honorific form *gsol* for *bzas* 'eat' and *btung* 'drink' goes with those objects having to do with foods and eating; e.g., *ito* 'food' → *gsol-chas*, *thab-tshang* 'kitchen' → *gsol-thab*.

1.4 Subject Honorifics

Just as the possession can be the target of honorification, one's being or action can be honorified as a way of showing deference toward the referent of the subject nominal, namely the actor. Of course, a subject nominal itself can be honorified by, for example, the choice of the second- or third-person pronominals (see above), but the case under consideration involves alternations in verbal form. A case can be clarified by comparing the plain Japanese sentence (a) *Tanaka ga ki-ta* (Tanaka NOM come-PAST), 'Tanaka came' and the honorific counterparts, (b) *Tanaka-kyoozyu ga ki-ta* (Tanaka-professor NOM come-PAST), and (c) *Tanaka-kyoozyu ga ko-rare-ta* (Tanaka-professor NOM come-HON-PAST 'Professor Tanaka came.' Sentence (b) with a professional title for the subject nominal expresses a certain degree of deference toward the teacher. But a more appropriate form would be sentence (c), in which the verb also changes its form in accordance with the speaker's deference toward the referent of the subject.

Japanese, Korean, and Tibetan have a highly developed system of subject honorification. As shown in the above example, Japanese uses the passive/potential/spontaneous suffix *-(ra)re* attached to a verbal stem and derives the subject honorific verbal form: *ik-u* (go-PRES) 'go' → *ika-re-ru* (go-HON-PRES). Korean has the subject honorific suffix *-si* that attaches to a verbal stem: *o-ta* (come-IND) 'come' → *o-si-ta* (come-HON-IND). Tibetan uses the honorific form *gnang* for the verbs of giving and receiving as a productive subject honorific verbal suffix; *thugs* 'meet' → *thugs-gnang* (meet-HON), *bzos* 'make' → *bzos-gnang* (make-HON).

Besides these productive honorific forms, a fair number of suppletive subject honorific forms are also seen in all of these languages. The Japanese form *irassyaru* suppletes *iru* 'be,' *iku* 'go,' and *kuru* 'come.' *Khesi-ta* is the Korean subject honorific form of *iss-ta* 'be.' The Tibetan form *gnang* seen above suppletes *ster* 'give,' *btang* 'send,' and *sprad* 'hand over.'

In addition to these, Japanese has a circumlocution subject honorific form. This involves the following processes: (a) the conversion of the verbal complex into a nominalized form, (b) the attachment of the honorific prefix *o-/go-* to the nominalized form of the verbal complex, and (c) the predication of the subject

by the verb *naru* 'become' together with the adverbial complement form of the nominalized verbal complex. This converts the sentence *Tanaka-kyoozyu ga aruk-u* (Tanaka-professor NOM walk-PRES) 'Professor Tanaka walks' into *Tanaka-kyoozyu ga o-aruk-i ni naru* (Tanaka-professor NOM HON-walk-NOMINALIZER DAT become), where the *o-aruk-ini* (HON-walk DAT) portion is the adverbial complement form of the nominalized verbal complex. Notice that this type of circumlocution is fully grammaticized in the sense that it is associated only with the honorific value, with no literal reading available. In fact, this grammaticization aspect is a basic defining characteristic of honorifics that distinguishes them from ordinary polite expressions such as English *Will you open the door for me?* and *Do you mind opening the door for me?*, which are still associated with literal meanings.

The Japanese honorific prefixes *o-/go-* also attach to adjectival predicates, yielding the third type of subject honorific form in the language; e.g., *Hanako wa utukusii* (Hanako TOP beautiful) 'Hanako is beautiful' → *Hanako-san wa o-utukusii* (Hanako-HON TOP HON-beautiful).

(Abbreviations in this section and below: NOM—*nominative*; ACC—*accusative*; HON—*honorific*; TOP—*topic*; PRES—*present*; IND—*indicative*; DAT—*dative*; HUM—*humbling*; GEN—*genitive*).

1.5 Humbling Forms

One may show deference toward a superior by humbling oneself or one's speech directed toward a superior. A fair number of languages have humbling first-person pronominals.

The ordinary Thai first-person pronoun *chan* is replaced by *phom* or by the even more humbling form *kha* '(lit.) servant' or *kha cau* '(lit.) master's servant.' Korean *na* 'I' can be replaced by the humbling form *co*. In letter writing, a Japanese male may humble himself by referring to himself by the Chinese derivative *syoo-sei* '(lit.) small person.' In fact, the Japanese epistolary style contains a whole series of honorific/humbling noun pairs adopted from Chinese; e.g., *rei-situ* '(your) honorable wife': *gu-sai* '(my) stupid wife,' *gyoku-koo* '(your) splendid article': *sek-koo* '(my) humble article.'

Less common are humbling verbal forms, which are sometimes called 'object honorifics,' because they express deference toward the referents of nonsubject nominals by humbling the actor's action directed toward them. The Japanese humbling forms include both suppletive verbal forms, e.g., *sasiageru* and *o-me ni kakaru* for *yaru* 'give' and *au* 'meet,' respectively, and a circumlocution, the latter being quite pervasive. The humbling circumlocultion involves (a) the prefixation of the nominalized verbal form by the prefix *o-*, and (b) the verb *suru* 'do.' This converts the plain form *Watasi wa Tanaka-kyoozyu o tazune-ta* (I

TOP Tanaka-professor ACC visit-PAST) 'I visited Professor Tanaka' into *Watasi wa Tanaka-kyoozyu o o-tazune si-ta.*

Tibetan also has a number of suppletive humbling forms of verbs; e.g., *thugs* 'meet' → *mjal*, *ster* 'give' → *phul*. *Nga pa-pha dang thugs byung* (I father.PLAIN with meet PAST) 'I met (my) father (plain)' → *Nga pa-lags dang mjal byung* (I father.HON with meet.HUM PAST) 'I met (my) father (humbling).'

Subject honorification and the humbling processes are controlled by the referents of different nominals—the former by the subject nominal and the latter by the nonsubject nominal—and thus they can be in theory combined. Indeed, such a combination appears possible in Tibetan (Kitamura 1974). As in the above example, the word *mjal* 'meet' is the humbling form expressing the speaker's deference toward the person to be met. As discussed in Sect. 1.4, *gnang* is the productive subject honorific form. The combination of the two, *mjal gnang*, thus expresses the speaker's deference to both the person who is meeting someone and the one who is met; e.g., *Pa-lags sku-mdun dang mjal gnang song* (father.HON Dalai Lama with meet.HUM HON PAST) '(My) father met Dalai Lama (humbling-subject honorific).' In the case of Modern Japanese, however, such a combination of a subject honorific form and a humbling form is generally avoided, and, when the occasion arises, simply a subject honorific form alone is used; e.g., *Tanaka-kyoozyo ga gakubu-tyoo ni o-ai ni natta* (Tanaka-professor NOM dean DAT HON-meet DAT became) 'Professor Tanaka met the dean (subject honorific).'

2. Addressee Honorifics

Addressee honorifics are those forms that show the speaker's deference toward the addressee. In the case of honorific second-person pronouns, the reference honorific function and the addressee honorific function converge, but certain languages have special addressee-oriented honorific forms.

Perhaps the most familiar is the use of *sir*, *ma'am*, etc. in English as in, *Yes, sir* or *Thank you, ma'am*. Many languages mark addressee honorifics by the use of particles; e.g., Tagalog *po*, Thai *kha* (female), *khrap* (male), Tamil *nka, lii*.

More elaborate systems are found in Korean and Japanese, both of which have special verbal endings. Korean attaches the suffix *-sumni* and Japanese *-mas*.

Notice that subject honorifics and addressee honorifics are again two independently parameterized systems, and therefore that one can, in principle, occur independently of the other. Thus, the Japanese subject honorific form *Tanaka-kyoozyu ga ika-re-ru* (Tanaka-professor NOM go-s.HON-PRES) 'Professor Tanaka goes' can be used by itself between two students. One can then combine the subject honorific ending *-(ra)re* (s.HON) with the addressee honorific

ending -*mas* (A.HON), when the same sentence is uttered toward a respected person; *Tanaka-kyoozyu ga ika-re-mas-u* (Tanaka-professor NOM go-S.HON-A. HON-PRES). When the subject referent is not appropriate for showing the speaker's respect, only the addressee honorific form can occur as in: *Watasi ga iki-mas-u* (I NOM go-A.HON-PRES) 'I go.'

In Japanese, even further respect toward the addressee can be shown by the use of humbling verbal forms. The last sentence above can be made even politer by suppleting the verb *iku* 'go' by the humbling equivalent *mairu* as, *Watasi ga mairi-mas-u*.

3. Avoidance Languages

The use of honorific forms may be conditioned by those who are in the vicinity, especially when a respected person being talked about is within earshot. Thus, a Japanese student who normally utters a plain form such as *Sensei ga ki-ta* (teacher NOM come-PAST) 'The teacher came' might use the subject honorific form *Sensei ga ko-rare-ta* when he notices the presence of the teacher in question.

Much more regulated forms of bystander honorifics are seen among the Australian aboriginal languages. The variation of language, known as the 'mother-in-law' or 'brother-in-law' language, is used specifically in the presence of certain 'taboo' kins.

In the case of the 'mother-in-law' language of Dyirbal, a speaker must switch from the 'everyday' language, Guwal, to the 'mother-in-law' language, Dyalnguy, when a taboo relative, e.g., a parent-in-law of the opposite sex, appears within earshot. Dyalnguy is in fact part of the avoidance behavior between certain taboo relatives that was once strictly observed in Australian aboriginal societies. A son-in-law avoids speaking directly to his mother-in-law, while the mother-in-law must use Dyalnguy in speaking to her son-in-law (Dixon 1972).

In Guugu Yimidhirr society, a male ego and his mother-in-law cannot speak to each other directly, and, accordingly, the avoidance language is more like a 'brother-in-law' language, for it is used typically when one speaks to his brother-in-law or father-in-law (Haviland 1979).

The avoidance language has an honorific function as well. In Guugu Yimidhirr, the brother-in-law language is a language to be used with certain kins that must be treated with respect. It is spoken slowly in a subdued voice accompanied by a behavioral pattern of avoidance of facing the addressee directly, e.g., by sitting sideways with some distance maintained. The Guugu Yimidhirr brother-in-law language also has linguistic features of honorific languages. For example, the everyday second-person plural pronoun *yurra* is employed as a second-person singular pronoun, as in the case of Russian *vy* and French *vous*. Honorifics often neutralize semantic

distinctions made in ordinary words, and so does the Guugu Yimidhirr brother-in-law language. The polite second-person pronoun *yarra* 'you' neutralizes the distinctions among the singular, the dual, and the plural forms. With various suppletive forms, certain brother-in-law expressions show a marked difference from the everyday language: e.g., *Nyundu buurraay waami?* (you water found) 'Did you find water?' (everyday)→ *Yurra wabirr yudurrin* (you water found) 'Did you find water?' (brother-in-law).

Speech behavior involving avoidance languages is akin to that of honorifics languages like Javanese and Japanese in three other respects. Voice modulation is also seen in Javanese honorific speech, where 'the higher the [honorific] level one is using, the more slowly and softly one speaks' (Geertz 1968: 289). In the feudal society of Japan, inferiors were not permitted to speak to their superiors of the highest rank in close proximity to them. Emperors received courtiers behind a bamboo screen, and warlords were addressed by vassals of lower rank from some distance away. Avoidance of superiors is also manifested in the use of second-person pronouns and names. In languages like Japanese, Korean, and Dzonkha the use of second-person pronouns is avoided in addressing superiors. Japanese, for example, has a polite second-person pronominal form *anata* or even more honorified form *anata-sama*, but these can never be used in addressing a superior; the latter is marginally usable in a highly impersonal situation. Likewise, in Japanese and many other societies (e.g., traditional China, Igbo), the given names of certain superiors cannot be used in addressing by inferiors.

One of the parameters that determines the use of honorifics is the social and psychological distance between the interlocutors (see Sect. 5). The avoidance languages of Australia and similar speech behaviors in honorifics languages point out clearly this correlation, which is often reinforced by physical distance.

4. Beautification

Japanese has extended the honorific prefixes *o-*/*go-* to other uses where no respect for the referent, e.g., the possessor of the designated object, or for the addressee is intended. Thus, one may attach the prefixes to the nouns designating what belongs to the speaker or to no particular person; e.g., *watakusi no o-heya* (I GEN HON-room) 'my room,' *o-biiru* 'beer,' *o-nabe* 'cooking-pot.' This particular use of honorific prefixes is simply motivated by the speaker's demeanor (see Sect. 5.1) and is called *bika-go* 'beautification language' in Japanese. The form is typically used by women, and accordingly those nouns that take beautification prefixes typically designate domestic matters such as household good and foods.

Though beautification prefixes are not strictly honorifics because they beautify even those nouns

designating objects belonging to the speaker, their honorific origins are not entirely obliterated. One cannot use the prefixes to those nouns designating highly personal objects belonging to oneself such as body parts. Even those who are prone to use beautification prefixes excessively would not use words such as *o-yubi* 'finger' or *o-asi* 'leg' in reference to their own fingers or legs, while they are perfectly appropriate as honorific forms used in reference to a respected professor.

5. Use of Honorifics

A more challenging aspect of the study of honorifics perhaps is the description of the actual use of honorifics in speech situations; e.g., who uses them, whom they are used in reference to, and what their functions are in communicative interaction. Since addressing these issues requires knowledge of actual speech situations in some detail, the focus here is on a single language, namely Japanese. But preliminary remarks on some general concepts are in order.

In the case of the avoidance languages of Australia (Sect. 3), their use seems to be controlled rigidly according to the tribal membership and genealogical relationships that determine for each speaker which kinsmen (e.g., mother-in-law, brother-in-law) are taboo and which are to be avoided and treated deferentially. Notice again that the notions of avoidance and of deference converge in the use of a special language. Indeed, the use of honorific speech in general is controlled by the social and psychological distance among the interactants.

5.1 Power and Solidarity

Brown and Gilman (1960), in a seminal work in this area, have identified two factors of 'power' and 'solidarity' that determine social and psychological distance relevant to the use of honorific speech. Power, as determined in each culture according to social class, age, sex, profession, etc., establishes the superior–inferior relationship that characterizes a vertical social distance—the greater the power difference is, the greater the social distance is. Solidarity, on the other hand, determines a horizontal psychological distance. Those having the same or similar attributes (e.g., power equals, members of the same family, profession, or political persuasion) are solidaristic or intimate and short in psychological distance, whereas those that do not share attributes (e.g., power unequals, strangers) are distant. Brown and Gilman have shown that these two differently defined parameters of distance are correlated with the use of pronouns in European languages (e.g., French *tu* vs. *vous*, German *du* vs. *Sie*). Since Brown and Gilman (1960), the former, plain forms are customarily referred to as 'T-forms' and the latter, honorific forms as 'V-forms' in the literature.

Power-based honorifics and solidarity-based honorifics show difference in the reciprocity of the forms used between the interactants. As in the case of German *du* used among intimates and *Sie* used between strangers, the solidarity-based honorifics are formally symmetric or reciprocal, whereas a strictly power-based system is nonsymmetric or nonreciprocal in that the inferior is obliged to use the honorific forms (the V-forms) toward the superior, who returns the plain forms (the T-forms). Brown and Gilman show that in the case of T/V variation in Europe, it was largely controlled by the power relationship until the middle of the nineteenth century, while in the twentieth century solidarity had become a dominant factor.

5.2 Power-based Honorific Pattern

Japanese honorific speech shows both power-based and solidarity-based aspects. Where superiority is fairly rigidly determined as in a business organization, where the rank and age difference are major determinants of superiority, the power-based, non-reciprocal pattern is observed; an inferior consistently uses honorifics toward a superior. A superior might thus invite his subordinate for a drink by using plain form, (a) *Konban nomi ni ikoo ka* (tonight drink to go Q) 'Shall we go drink tonight?' The subordinate must reply in the addressee honorific form as (b) *Ee, iki-masyoo* (yes go-A.HON) 'Yes, let's go,' and never reply in the plain expression (c) *Un, ikoo* 'Yeah, let's go,' which is appropriate to his inferior or equal. When the subordinate asks his superior out, the reverse pattern obtains; the subordinate cannot use (a) and must use its addressee honorific version, (d) *Konban nomi ni iki-masyoo ka* 'Shall we go drink tonight?' and his superior is most likely to reply with the plain form (c).

As far as the inferior is concerned, this pattern of exchange must be maintained even if he and his superior are quite intimate and can converse quite informally. The mutual use of plain speech between non-equals is permitted only in an unusual circumstance like during the late hours of a drinking party, when all the formalities might be done away with.

5.3 Solidarity-based Honorific Pattern

Whether or not a superior uses honorifics toward an inferior depends on a number of factors. Among them, a major factor is psychological distance or degree of intimacy. Though one occasionally witnesses the use of plain or rough speech motivated by power on the part of the superior, it is becoming increasingly rare in contemporary Japanese society to see the power-based use of plain form—a major exception being a scene of conflict or dispute between power-unequals, e.g., between an angry

customer and a sales clerk. This trend is due to several factors.

Thus, when a superior uses plain forms towards his intimate subordinate, it is a mark of intimacy, whereas his use of honorific speech creates a distance and is a sign of formality. In other words, a superior's use of honorifics is solidarity-based (but see Sect. 5.4); honorifics are used (as in sentence (d) above) when a superior and his subordinate are not very intimate, while plain speech (e.g., sentence (a)) is directed toward the subordinate as a sign of solidarity, whereby the sense of camaraderie is engendered. Notice, however, that between power-unequals, only a superior has the option of using plain forms—inferiors must always use honorifics—unlike the mutual T-form exchanges in Europe. (Even in Europe, it is power superiors who can initiate the reciprocal T.)

Between power-equals, the plain/honorific variation is by and large controlled by the solidarity factor; plain forms are used among intimates to confirm camaraderie, while honorifics are used between less familiar persons and strangers as a means of keeping psychological distance, by way of which the addressee's personal integrity is honored (but see Sect. 5.4).

In the majority of contemporary Japanese households, the solidarity factor has primacy over the power factor, and thus parents and children and elder siblings and younger ones also exchange plain forms, much like the use of *du* within the contemporary German family. This is one linguistic manifestation of the Western egalitarian ideology, which was introduced to Japan in the middle of the nineteenth century and which spread throughout the country after World War II.

China has witnessed perhaps the most dramatic effect of the egalitarian ideology on honorifics. The socialist revolution in 1949 and the cultural revolution of the 1960s wiped out the traditional social classes, and with the demise of the aristocratic and the elite classes, once-flourishing honorifics too were all but obliterated.

The other manifestation of the egalitarian ideology is the use of honorifics on the part of power superiors, as described above. Even Emperor Akihito of Japan uses honorifics when he addresses an ordinary citizen. Thus, the egalitarian ideology has facilitated the growth of reciprocal solidarity-based use of honorifics in Japanese as well.

But the reciprocal speech pattern can in principle go in either direction; toward the symmetrical honorific pattern or toward the symmetrical non-honorific, plain pattern. As noted above, Chinese has taken the path to the latter. Besides the solidarity factor discussed above, there seems to be another prevailing factor at work in those languages that display the reciprocal honorific speech pattern.

5.4 Demeanor

In some Japanese families, especially between husband and wife and/or between parents and adult children, daughters in particular, nonreciprocal plain/honorific exchanges can be observed. But the motivation for such an exchange seems hardly to be power-based. Instead what underlies speech patterns observed in those families is the idea of proper language usage, which prescribes that superiors be treated deferentially through honorific speech. After all, honorifics are consciously taught and learned by the Japanese with this kind of prescriptive idea. This conscious teaching and learning of honorifics and their historical connection to the nobility has produced a situation in which appropriate honorific usage is regarded as a mark of good breeding.

The use and nonuse of honorifics as indications of class membership has the effect of making the use of honorifics part of the speaker's self-presentation effort, an aspect of what sociologist Goffman (1956, see *Goffman, Erving*) calls 'demeanor.' That is, while correct honorifics usage has the effect of paying respect to the addressee, it is at the same time a way of presenting the speaker himself as a cultivated person of good demeanor.

The demeanor aspect of honorifics usage also has the effect of producing the reciprocal honorific speech pattern, for speakers who have the prerogative of using either plain or honorific speech, as in the case of the Emperor, or power superiors in the business world, or professors in academic life, may constantly use honorifics as a way of self-presentation. An extreme manifestation of this in Japanese is the excessive use of the beautification prefixes *o-/go-* by women (Sect. 4), whereby the level of politeness is consciously elevated to an absurd level at times.

5.5 Formality

Though this article has tried to isolate and delineate those factors that determine the use and non-use of honorifics, they do not in reality occur in isolation. In an actual speech situation all these factors that control speech form are typically compounded. Take the notions of solidarity and of demeanor discussed above. When a woman shops in an elegant boutique in Ginza in downtown Tokyo, she is likely to use honorifics, as in *Motto ookii no o-ari ka sira?* (more large one HON-have Q wonder) '(I) wonder if (you) have a larger one? (honorific),' as opposed to a plain form such as *Motto ookii no aru?* (more large one have Q) '(Do you) have a larger one? (plain),' which might be used when she is shopping in a neighborhood grocery shop. Here, it is likely that both solidarity and demeanor factors are at work. In addition, the formality factor involved in the former situation cannot be ignored.

Formality overrides all the considerations discussed above and requires the use of honorifics on the part of all the concerned parties. Thus, power-equal colleagues, who normally exchange plain forms, would exchange honorifics in a formal meeting or on ceremonial occasions. Other factors contributing to the formality of the speech setting include the nature of the topic of conversation and the turns of conversation that occasion formality such as opening and closing of a new topic.

One clear instance where the formality factor alone dictates the use of honorifics is letter writing. Letter writing is a formal activity, being associated with a long history of a variety of epistolary styles, and it triggers the use of honorifics even if the letter is addressed to an intimate person. For example, a son, who usually uses plain forms to his mother, would write to his mother in the honorific style: On the telephone, he would say to his mother *Raisyuu kaeru yo* (next week return PART) '(I'll) come home next week, all right? (plain),' but he would write, *Raisyuu kaeri-masu* in the addressee honorific style.

5.6 Relativity of Social Distance

One final characteristic of Japanese honorific usage to be discussed here has to do with the relativity of the social distance of a nominal referent. The use of both subject honorifics and humbling forms is essentially determined by the social and psychological distance between the speaker and the nominal referent as described above. One would use a subject-honorific form when the subject referent is a superior or a humbling form when one's action is directed toward a superior. When this kind of pattern is absolutely maintained, regardless of the nature of the addressee, as in the case of the Korean honorific system, then a so-called absolute honorifics system exists. The Japanese honorific system differs from this in that the group identity of the addressee enters into the picture of proper honorific usage.

Japanese society makes a rather clear division between those who belong to one's social group and those who are outside. With respect to outsiders, insiders are treated as an extension of oneself. One consequence of this in regard to honorifics usage is that, with respect to outsiders, status differences among the members of a given social group are obliterated and members are identified with the status of the speaker. Accordingly, when speaking to an outsider, one would not use honorifics with respect to a member of one's social group, e.g., family members, colleagues in a business firm; humbling forms would be used instead even with respect to the superior's action. For example, a secretary would normally use honorifics with respect to her boss when she speaks to her colleagues, as (a) *Syatyoo wa soo ossyatte imasu* (company-president TOP so say.S.HON be.A.HON) 'The company president

says so (subject honorofic, addressee honorific).' But when she is speaking to someone from outside her own company, she would treat her boss as if he were herself and would use humbling forms, as (b) *Syatyoo wa soo moosite orimasu* (company-president TOP so say.HUM be.HUM.A.HON) 'The company president says so (humbling, addressee honorific).'

Thus, in Japanese, with its relative honorifics system, the interpretation of honorific value is not as straightforward as in absolute honorifics languages like Korean and Tibetan, in which the (a)-type honorific form is consistently used regardless of the addressee. That is, in Japanese, the interpretation of the honorific index (see Sect. 6) must take into account not only the usual relationships among the speaker, the nominal referent, and the addressee, but also whether the addressee is an insider or outsider with respect to the speaker's social group.

6. Conclusion

Human interaction is facilitated by minimizing conflict between interactants. One of the ways in which conflict arises is by mistreating people such that they feel their personal integrity is threatened, that the expected camaraderie is not confirmed, or that the deference their social standing has earned them has not been paid. Potential conflict is therefore removed when clarification of the relationships of the involved parties is made, and when they are maintained and reinforced with attendant protocols throughout an interaction.

Human behavior, verbal or otherwise, is polite to the extent that it satisfies these requirements for facile interaction. Honorifics permit the speaker to express his relationship to the addressee and the nominal referents in a highly codified manner. They indicate a speaker's recognition of the power and personal integrity of the person spoken to or talked about, and conversely they indicate a speaker's social and psychological position in relation to the involved parties. Thus honorifics remove potential conflict and facilitate communication. It is precisely because of this function of honorifics for smooth communicative interaction that they instantiate a prototypical case of politeness phenomena of language use, and this in turn inspires a study of honorifics within the framework of general theories of linguistic politeness, a field gaining increasing attention thanks to work such as Lakoff (1975) and Brown and Levinson (1987).

Apparently all languages, regardless of the degree of elaboration in the honorifics system, have ways of making speech behavior polite. An interesting issue therefore is what difference, if any, possession of a highly elaborate honorifics system entails in the communicative function of languages. The relevant research, such as Hill et al. (1986), indicates that languages with honorifics are more strongly indexical than those languages like English that lack an

elaborate honorifics system. That is, different honorific forms are used according to different types of addressee, and thus honorific forms indicate the types of interactants. Hill et al. (1986) show that American students use the same expression of *May I borrow your pen?* to fairly diversified categories of people, such as professors, strangers, physicians, and store clerks. On the other hand, Japanese students would use the super-polite form *Pen o okarisitemo yorosii desyoo ka* '(lit.) Is it all right if I humbly borrowed your pen?' specifically to their professors, while using the middle-level polite form *Pen o kasite itadake masu ka* '(lit.) Is it possible that you give me the favor of lending me your pen?' for a class or people including strangers, physicians, store clerks, etc. Clearly the Japanese students' speech form sets their professors apart from other categories of people they interact with, reflecting the distinct status that the Japanese students, unlike their American peers, accord to their professors. In other words, the most elaborate honorific expression indexes the occasion in which the most relevant power superior is involved.

This kind of indexing function of honorifics is much more clearly seen in those languages in which speech levels are more rigidly determined in relation to speech situations. A given speech level, called 'register' precisely for the reason being discussed here, in such a language indicates clearly what sort of interaction is involved. For example, Javanese has as many as ten speech levels, and each register indicates the nature of interactants (Sakiyama 1989). For example, the low, ordinary style (*Ngoko lugu*) is used when elders address younger ones or between intimate friends. The middle style (*Madyå ngoko*) is used among female itinerant merchants, among country folk, and when the nobility address their subordinates. The highest form (*Kråmå inggil*), on the other hand, is used when a superior is to be treated with special deference (see also Geertz 1968).

Honorifics, in sum, convey the social meaning as opposed to referential meaning a sentence is normally understood to express. They indicate, among other things, the social categories of the people with whom the speaker is interacting. This in turn has the effect of making the speakers of an honorifics language more attentive to those factors (e.g., age, wealth, occupation, family background) that determine the categories of people. The speaker must ascertain quickly what kind of people he is dealing with so as to choose honorific forms appropriate to his interactants. Thus the presence or absence of an elaborate honorifics system may have a rather profound effect upon how people perceive their environments and how they structure their communicative strategies.

Ideology

A. Luke

The term 'ideology' refers to systems of ideas, beliefs, practices, and representations which operate in the interests of an identifiable social class or cultural group (see *Representation; Social Class; Class and Language*). Common usages generally fall into two categories: a critical definition allied with Marxist theory and a relativist definition used in liberal social theory and popular Neo-Liberal discourse (see *Marxist Theories of Language; Discourse*). In Marxist and Neo-Marxist social analysis, the term specifies distorted ideational and linguistic representations of economic reality and social relations that have their sources in, and disguise, political and economic functions of class domination. In liberal social

sciences and in the Western popular press, the term marks out configurations of ideas, beliefs, and values ascribed to particular populaces, political formations, and subcultures. These should be taken as provisional definitions only; across the social sciences, debates are going on over what ideology is, how ideology works in the modern and postmodern state, and its connections with language and discourse. Historical and contending definitions retain currency in contemporary social theory. Yet, an examination of the complex relationship between ideology and language, tied to differing understandings of social structure and the human subject, has eluded much contemporary linguistic theory and research. The unresolved problems in such work point to the need for a rethinking of ideology in light of continuing developments in critical linguistics and discourse theory (see *Critical Sociolinguistics*; *Discourse*).

1. Ideology in Critical Social Theory

Following its initial use to describe the claims of 'ideologues' in the aftermath of the French Revolution, Marx and Engels (1970) redefined ideology as a systematic distortion in perception of social and economic relations. This definition remains central for explaining 'false consciousness,' a misrecognition of one's class position and an embrace of a particular system of ideas and understandings which serve dominant interests. It is based on the possibility of nonideological perceptions and understandings, of an emancipatory class-consciousness developed in concert with a science of historical materialism. For Marx and Engels, language is 'practical consciousness,' arising from the functional necessity of concrete social, and economic relations. This formulation of the relationships of ideology, consciousness, and language became a central feature of Marxist doctrines of language through the work of Stalin; Marr, and others.

In their critique of Formalism and nineteenth-century European linguistics, Bakhtin and Voloshinov (see *Voloshinov, Valentin Nikolavic*; *Bakhtin, Mikhail M.*) moved beyond doctrinal explanations. They too maintained that language and semiosis are imbedded in 'concrete social reality' which in turn consists of an 'ideological environment ... [of] realized, materialized, externally expressed social consciousness' (Bakhtin and Medvedev 1985: 16–17). The word is the 'ideological phenomenon par excellence' because it stands, unlike other forms of semiosis, 'wholly absorbed in its function of being a sign' (Voloshinov 1973: 13–14). Yet ideology is not a possession of mind, a corpus of illusions and abstract ideas residing in consciousness; it has a material social existence in language, text, and discourse. Accordingly, language use is not explicable by reference to a creative, autonomous speaker/writer.

Rather the subject is constrained and shaped by the available stock of situations and signs, texts and genres. These constitute cultures', communities' and individuals' discourse resources. Nor can ideology be explained in terms of a dominant, inescapable set of meanings. Because lived and experienced 'behavioral ideology' is less formally framed and constraining than institutionally 'established' ideologies, the subject retains an agency for the 'partial or radical restructuring of ideological systems' (Voloshinov 1973: 93). Within this milieu, particular texts are not univocal expressions of dominant ideologies. All texts are 'heteroglossic' expressions of other voices and texts, genres, and social contexts (Bakhtin 1981). Nonetheless, this does not prevent 'the ruling class ... [trying] to impart a supraclass, eternal character to the ideological sign' (Voloshinov 1973: 23), closing down its 'polyphonic' semantic possibilities and making it 'uniaccentual.'

Language and semiotics, seen as a complex politics of representation, thus ideologically position the language-using subject. Yet despite a recognition that 'there is no such thing as experience outside of embodiment in signs' (Voloshinov 1973: 85), for Voloshinov ideology remains contingent on a material reality outside itself. Language becomes the terrain on which 'class based struggle' for the representation of the real is waged. Language change is therefore the extension of 'differently oriented social interests within ... the same sign-community' (Voloshinov 1973: 23).

The nexus of ideology and language remains central in the social science debate over the degrees of power (see *Power and Language*) that can be assigned to social structure and human agency (Therborn 1980, Thompson 1984). In many respects, Bakhtin and Voloshinov set the terms for current work: the challenge of a comprehensive social and linguistic theory that explains how ideology constructs and positions the human subject through language, and how that subject uses language as a material means for entering into history and engaging the social world. This role of textually coded ideology in positioning and enabling the subject is taken up in structuralist semiotics. A primary ideological effect of text semiotics is to make social and historical configurations appear natural and inevitable (Barthes 1972). Textual ideologies hide themselves and their artifice, insulating themselves from recognition and critique. The key to this reconceptualization is a rigorous skepticism towards referential theories of language. Ideologies thus cannot be construed as independent ideas with freestanding referents, but indeed are constituted by the play of differences between and within systems of signification and representation. This play of different signs can effect closure of possible meanings and understandings (Eco 1976), making the text and its

readings 'uniaccentual.' It is thus difficult to establish whether an utterance or text is ideological solely by reference to extant economic conditions or social relations outside of itself. Nor can a discourse-free perception of social and material reality or, for that matter, consciousness or concepts with a life of their own outside of language, texts and intertextuality be claimed.

This perspective signals a major shift in ideology critique from analysis of social structure (see *Social Class*) to text structure and discourse configuration. Yet while ideology may not be a simple reflection of a material base, it remains an articulation of the unspoken values of dominant classes (Althusser 1971). The ritual practices of ideology are lodged within what Althusser termed 'ideological apparatuses': schooling, media, church, and so forth. These institutions are the cultural sites where ideologies are transmitted to and internalized by the subject as valid knowledge, beliefs, and explanations. Although it is an expression of dominant class interests and leads to misrecognition of one's relations to the means of production, ideology is not a direct consequence of economic relations. It takes on a material existence of its own in the cultural domain. Yet, for Althusser, it remains an over-arching, controlling entity operating through institutional 'interpellation': ideology 'hails' and 'recruits' individuals into categorical status as subjects.

This model of ideological interpellation has been criticized for its downplaying of human agency and the possibilities for resistance. Hence, much Neo-Marxist theorizing has turned to broader conceptions of cultural hegemony drawn from Gramsci (1971) (see *Hegemony*; *Gramsci, Antonio*) which stress the human subject's active participation in rule by consent' through immersion in forms of cultural signification. A similar construct is found in Voloshinov's (1973: 94) specification of a 'behavioral ideology,' a 'whole aggregate of life experiences and the outward expressions directly connected with it.' This alternative position is critical of notions of ideology as a unitary, all-encompassing consciousness from which there is no escape, and it stresses the role of language in both positioning the subject and enabling contestation.

Ideological interpellation can only occur through a field of meanings. Pêcheux (1982: 187) observes: 'a meaning-effect does not pre-exist the discursive formation in which it is constituted. The production of meaning is an integral part of the interpellation of the individual as subject.' Semantics can be seen as tied to ideological configurations; ideologies have a material deployment only in institutionally located discourse. For Pêcheux, class struggle is manifest in discourses that traverse particular speech situations and texts, ordering words and meanings. Discourses in institutional sites of ideological apparatuses

constrain 'what can and should be said' (Pêcheux 1982: 111), and thereby produce the subject as the object of *discourse*. Yet neither discourses nor ideologies are unitary and all-encompassing: meanings are constituted and indexed by 'interdiscourse' and thereby become the very sites of struggle between a multiplicity of contending ideologies. Nevertheless, language, discourse and thought retain in the first instance a basis in 'a given moment in the development of class struggle' (1982: 184).

Social and semiotic theory, then, has moved from the analysis of ideologies as dominant and distorting systems of ideas to a definition of ideologies as material discourse practices both shaped by and shaping of the social and economic domains. But a gap remains between macrosocial theories and microlinguistic analyses. The task of integrating concepts of ideology into linguistic theories and of developing analytic techniques for studying ideologies in everyday speech and texts has proven more elusive.

2. Ideology in Linguistic Theory and Analysis

Descriptive linguistics, various branches of sociolinguistics and the ethnography of communication have stopped short of theorizing ideology, the state, and power. Descriptive linguistics takes language as a synchronic object of study, uncontaminated by the social and political. While some significant attempts at articulating a political linguistics have been undertaken (Mey 1986), work in the sociology of language has stopped short of engaging with the foregoing concerns raised in social theory and the philosophy of language.

This limitation has its basis in theories of the sociolinguistic subject. In most models, the subject is seen as the source of speech, discourse, and text. Although situated in and influenced by social context (see *Context*), utterances and texts remain explicable in terms of individual intents and goals, which in turn are seen to reflect social norms, functions, and procedures. The absence of a normative social and political analysis precludes examination of the ideological role of discourse in the formation of the speaking subject. This location of ideology within the subject also characterizes cognitive and psycholinguistic models of text processing. Where it is taken up at all, ideology is explained in terms of cognitively organized clusters of attitudes and knowledge developed in close relation to individual and group interests. As in other contemporary information theory, text macrostructures, and mental schemata are seen as neutral ideational formations, akin to Kuhn's paradigms, that exist within social organizations without political economies.

By contrast, Halliday's theorization of language as social semiotic begins from a recognition of the relationship of social structure and language,

stressing that language development and use is not subjective and psychological: 'it is not only the text (what people mean) but also the semantic system (what they can mean) that embodies the ambiguity, antagonism, imperfection, inequality and change that characterize the social system and the social structure' (Halliday 1978: 114). The insight that social function precedes linguistic form foregrounds the social, potentially ideological bases of semantics and lexicogrammatical structures. In this way, systemic linguistics offers frameworks for establishing the ideology/discourse/language relationship theorized by Pêcheux. Further, Halliday develops a dialectical model of semiotic representation and reality, an undertaking that 'social reality is shaped, constrained and modified' by social semiotics (1978: 126). But while systemic linguistics locates language codes in ideological configurations, drawing on Vygotsky (1987) to stress the sociogenesis of meaning its theory of society remains structural–functionalist, and its stress on social hierarchies, roles (see *Role Theory*), norms, and status stops short of a full theorization of state, class conflict and power.

Beginning from Halliday's critique of generative grammars, critical linguistics sets out to theorize and explicate asymmetries of power between class and gender interests in conversation and written texts (see *Power and Language*; *Gender and Language*). Kress (1989) and Fairclough (1989) take the position that all discourse is mediated by institutions which, in turn, position readers and writers, speakers and listeners in differential positions of power and knowledge. The task of critical linguistics thus becomes the unmasking of the role of ideology in everyday social and textual relations, and the analysis of the linguistic transformation of ideological positions and values into a natural and transparent common sense. Kress and Hodge (1979), for example, examine how syntax constructs conflicting versions of agency and action in social structure, focusing on the lexicogrammar of differing accounts of a strike. Particular generic and literary conventions, syntactic choices can act as ideological devices, 'positioning' readings and controlling interpretations (Kress 1989).

In critical linguistic studies, analyses of classroom and interview transcripts, for instance, are used to trace asymmetrical speech acts and situations (see also Habermas 1984) and the unequal educational distribution of linguistic competence as cultural capital (see also Bourdieu and Passeron 1977) (see *Symbolic Power and Language*).

Fairclough (1989) recognizes that ideology is constituted through discourse and, moreover, that discourse is dialogical, produced by and producing the social relations of addressors and addressees. However, in many critical linguistic analyses, ideology remains conceptualized as a set of ideas which serve class interests (see *Class and Language*; *Power and Language*). For example, Kress and Hodge's (1979) analysis of strike reportage presupposes a systematic distortion of a social reality outside text and discourse *per se* (i.e., there is an authentic, reportable version of the forces and power at work in the strike). Hence, while critical linguistics takes up Foucault's notions of discourse as technology for moral and political regulation (Chouliaraki and Fairclough 1999), its claim that some discourses and texts can be nonideological, nonsexist, and indeed emancipatory, again suggests an ideology/discourse/social reality differentiation. Yet the normative and linguistic grounds for distinguishing ideological from emancipatory texts and conversational exchanges remain unexplicated.

3. Ideology, Discourse, Power

The relationships between ideology, language, and discourse are being explored as key areas of social theory and linguistic inquiry. A central problem facing social theory and analysis is the impossibility of pursuing ideology as an entity in and of itself, independent of and preceding the sites and formations of discourse (Foucault 1980). For its part, linguistic analysis requires an expanded theorization of social structure and conflict, and unequal power and knowledge relationships. The task of connecting ideology with language, of joining macrosocial theory with close textual analysis of spoken and written texts may require new hybrids of linguistics, critical sociology, feminist, and discourse theory. But such efforts should be tempered with Voloshinov's and Pêcheux's insight that linguistic theorizing itself is not outside ideology. It too constitutes a discourse which may represent and work in the service of particular dominant interests.

A further consideration for the study of ideology and language is the emergence of globalized service and information-based economies which rely extensively on language, discourse, and information as commodities for exchange. This move from industrial modes of production to multinational 'modes of information' (Poster 1990) underlines the difficulties facing Marxist analyses that proceed from a separation of economic base and cultural superstructure (Williams 1977), with language and discourse seen to reside in the latter (see *Marxist Theories of Language*). A social and linguistic theory of ideology is incomplete without attention to changing economic and political control over the actual media of textual representation. One recourse is to reconceptualize language as labor, subject to economic and cultural orders governing its production (Rossi-Landi 1975), and to focus on language and discourse as 'cultural capital,' with a constitutive role in the cross-generational reproduction of power and status, class and gender (Bourdieu and Passeron 1977). Future work

can begin from the redefinition of ideologies as plural practices which are effects both of discourse and of extradiscursive material conditions. Current work focuses on how language as a principal form and cultural capital is made to count. Such a theorization is also helpful within political theory for analyzing the efficacy of discourses as forms of political critique and strategy, and within feminist theory for analyzing the role of ideology in patriarchal discourse.

If indeed ideology is always constituted within and deployed through discourse, then the strategic power and knowledge relationships between institutions, social movements and collectivities, and among discourse-based ideologies bear further scrutiny by critical linguistics. In large part, the task has remained unchanged since Bakhtin and Voloshinov's work: the development of discourse analysis as a form of ideology critique which attends to larger matters of social structure and retains explanatory power in the analysis of everyday texts and utterances.

Language Conflict

D. P. Pattanayak

Language conflict is as much a feature of dominant monolingual countries as of multilingual countries and is related to language use. Choice of a dialect, a language, medium of instruction, medium of communication, medium of administration may be so manipulated as to result in conflict. From another perspective conflict may arise because of linking and delinking of identities, ethnicities, attitudes and use, disuse, and misuse of language in different domains.

1. Language Conviviality versus Language Conflict

Language signals conviviality as well as conflict. It is the seam where human communities communicate and cooperate; it is where they separate and differentiate. It is the basis of family cohesiveness, society formation, as well as of national integration. When, in order to escape from insoluble conflict or irreconcilable contradictions, people abandon the meaning structure of their culture, new group formation results. A nation may disintegrate if competing loci of standard try to establish exclusive identities.

Language provides identity to a group. Maintenance of border is one of the mainstays of linguistic identities. However, language borders are often fuzzy. In a multilingual situation the languages

563

merge their identities and subsume the smaller identities under a macro label without losing the smaller ones. Thus, Attic, Doric, and Ionic which were at one time in complementary use were known as Greek; in India Bhojpuri, Maithili, Magahi, Braj, Avadhi, Rajasthani, Pahari, etc., are known as Hindi. Languages sometimes split, accepting new identities and rejecting overarching identities in a process of differentiation. Venetian trying to establish its identity distinct from Italian, Konkani rejecting the overarching suzerainty of Marathi and forming a new State in the Indian Union are examples of these.

2. Conflict in Socialization

Socialization processes differ in different cultures, but the academic tendency to generalize often results in tension. Murray, after generalizing the Western experience, contends that the nuclear family provides greater coping ability for children to meet the contingencies of modern life. In Asia, Africa, and Latin America, the results of socialization in extended family structures are completely ignored by the above statement. In a monolingual country, in the process of enculturation, conflict in family roles caused by defective or distorted communication may result in permanent deformation of the personality of the child. Socialization in the home dialects as well as the standard are possibilities. In a multilingual environment a child may grow up with as many as six mother tongues. An Oriya man married to a Tamil woman speaking English at home, living in the Bengali environment of Calcutta and the children growing up with an Hindustani ayah and a Nepali security man has the initial socialization in six languages. As in monolingual situations dialects are used for complementary purposes, in a multilingual situation different languages are used in different domains and situations. In such situations languages are not adversaries, though because of later attitudinal developments conflicts may ensue.

3. Language Conflict

Language conflict results from the assertion of one variety of a language or of one language among many. Variation is the nature of living organisms. Language is no exception to this. Many varieties of a language in a dominant monolingual situation and many languages in a multilingual situation coexist where varieties are used in defined domains and for specific purposes. When one of them aspires to be the sole medium of expression or the sole conduit for attainment of rank, status, and wealth in society, conflict may result.

While the instrumental role of language and social mobility may cause conflict, the integrative role may also result in conflict. Conflict resolution mechanisms in different parts of the world give better insight into

language conflicts. The melting-pot theory in the USA predicted that different identities would be melted and fused to form an American identity. After 200 years of experimentation, it was found that the pot was melted, not the identities. A new theory, the salad-bowl theory, was then suggested. As in a salad bowl different entities retain their individual identity, similarly within a nation state different languages retain their identities. However, the metaphor of an edible dish speaks eloquently of the approach towards different languages. Joining the mainstream is the euphemism that the majority languages use for assimilation. They expect that all minor and minority languages would lose their identity and be assimilated to the majority language. That after 200 years English is declared as the official language of the USA under the Hayakawa Amendment makes explicit the majority expectations.

In Paraguay, Spanish, spoken by 5 percent or fewer of the population, was inflicted on the remaining 95 percent Guarani speakers. A similar situation exists in the Jammu and Kashmir State of India where the minority language Urdu is the State language though the majority speak Kashmiri. Where majority languages are suppressed and minority languages act as colonial languages, there is bound to be conflict. English with its colonial heritage in the non–english speaking world comes into conflict with majority languages as it seeks to usurp their function.

3.1 Conflict of Dialects

A good example of conflict of dialects is that between Black and White dialects of English. White American English is so much publicized as the standard that universities in the Middle East which have arrangements with American universities for educational cooperation refuse to accept American Black or Brown speakers of English as teachers. In the UK, there is a three-way conflict between the Jamaican Creole, the late-twentieth-century Black variety of English, and Standard English. In India, Hindi was known by different names in different periods of history. In the late twentieth century speech varieties like Bhojpuri, Maithili, Rajasthani, and Pahari are staking their claim as different languages in a spirit of identity assertion. Language loyalty made speakers of different varieties choose a single literary idiom for reading and public interaction. The same language loyalty when politicized to mobilize groups for ensuring closer political participation for the minorities results in language conflict. The socioeconomic competition among these groups spurs them into developing newer standards. Though Serbian and Croatian in the former Yugoslavia, and Hindi and Urdu in India, are two styles of one and the same language, they are perceived in each case as two different languages and conflict between the two

564

communities has, in the case of the former Yugoslavia, resulted in war and political instability.

3.2 Conflict of Scripts

Writing dates back to about 5000 years in human history. With variations in writing systems and greater variation in spoken words there is no wonder that there would be conflict as to which writing system should receive primacy over others. Thus it has remained a moot point as to whether new scripts should be invented for unwritten languages or they should be written using one of the existing writing systems. In India, the Sanskrit language continued to act as the cultural standard as it was permitted to be written in different scripts of the land. Sometimes the independent status of languages depends on the separation of scripts. Panjabi written in the Gurumukhi script and Urdu written using the Perso-Arabic script owe their identity to these scripts. Were they written in Devanagari, the fear is that they would lose their identity.

One of the extreme forms of script reform is the replacement of one script by another. The replacement of the Arabic script of Turkish by Roman was at one time considered as a great act of social reform. The romanization of Chinese does not have the same credibility. Chinese script is the unifying force among the different Chinese dialects. In the romanized form it is bound to lose the cohesive force which binds different dialects together and consequently it would be the first step towards conflict among the contending varieties. The revival of Hebrew with the Talmudic script is one of the newest wonders of the world. In a rare act of expression of identity a dead language as well as a dead script has been revived.

In India, there is evidence of one language being written using different scripts and at the same time there is evidence of one script being used for writing many languages. While in the case of Hindi and Marathi, Nagari script is the medium and is so accepted without serious political objections, in the case of Bengali, Assamese, and Manipuri using the Bengali script, there is a good deal of political objection against the Bengali script. Although the scripts employed for writing Kannada and Telugu differ only in diacritical marks on a few letters and this constitute a single script, they are treated as two scripts as are the Bengali and Assamese scripts which, too, differ only in a few letters.

In India, the two important conflicts regarding scripts are the Bodo and the Santhali scripts. The Bodo language in Assam, which was earlier written in the Assamese script, rejected the script in favor of the Roman alphabet as a mark of distinct identity. Confronted with the drawbacks of Roman alphabet, the Bodo speakers finally chose the Nagari script for their language. Santhali, spread over many linguistic states, was written using Oriya, Bengali, Nagari,

and Roman scripts. One of the Santhali elites devised a script, Ol Chikki, which became the fifth contending script and began displacing all the others. Both the script movements are connected with political movements for separate statehoods, in one case Bodoland and on the other Jharkhand. Script movements in both cases are symptoms of a deeper malady of socio-economic exploitation of the concerned groups.

3.3 Conflict of Styles

Choice of a style sometimes leads to conflict. In the controversy whether Hindi should have a Sanskritized or Persianized style, Gandhi had suggested a mixed style, Hindustani, which was not acceptable to the Hindi elite. As a result, Hindi and Urdu remained in a permanent state of confrontation. While the use of a high Sanskritized style makes Hindi accessible to the regional educated elite, it results in a growing chasm between the elite and the masses. In Telugu until the late 1980s books were written in Granthika style which was nobody's spoken language. Due to social pressure it has to be replaced by Sista Vyavaharika style.

3.4 Conflict in Standardization

Whether it is corpus planning or status planning, language standardization is prone to conflict. The quantum and sources of borrowing, creation of neologisms, the manner and nature of enrichment, all of these may lead to controversies. Which language variety or style should be given prominence in the production of reading material, which dialect should be accepted as the basis for the standard are issues which spark controversies. Shifting standard can be seen between the non-acceptance and acceptance of the split infinitive by the BBC as well as shift from Poona Marathi to Bombay Marathi. There is divergence between the spoken and written standards of a language. Effecting cohesion and coherence between the two sometimes may appear insurmountable. The difference between spoken and written Arabic is as much as between two different languages. However, as one is used for scriptural purposes and purposes of writing documents and the other in other domains, they are complementary and not conflicting. Status planning of languages generates conflict because of conflicting goals, ideologies and evaluative criteria. Standardization lends status to a language. Therefore controversy and conflict generated by standardization assume greater proportions in the study of planning for languages.

4. Conflict of Attitudes

There are approximately 3000–5000 languages in the world. Whether it is for diplomacy or exploration, for commerce or for exploitation, friendship and

interdependence, people speaking all these languages must communicate to collaborate. In this process of communication, however, different attitudes color perceptions. With the development of dominant monolingualism as the point of departure in the West, multilingualism was associated with under development, poverty, malnutrition, and diseases. With the development of nation states around unitary symbols in the West many mother tongues were seen as a threat to the nation state. Western elitism had reached such heights that in thirteenth-century England, the English language was forbidden in the schools where French, the language of the normal elite, and Latin, the classical language, reigned supreme. Elitism had assumed such proportions that mother tongue, community language, ethnic language, and even dialect assumed pejorative import and became labels for minor and minority languages.

The attitudes of loyalty and the attitude of pride may cause conflict. Loyalty can be instrumental in bringing about cohesion as well as disaffection and disintegration. Similarly, the recognition of pride of others might result in respect for the different, or the assertion of the superiority of pride might condemn the different as deficient.

In a stratified pluralist society diverse attitudes to a single phenomenon are to be seen at any one time. In a situation where language distance is measured, the attitude of the dominant language speakers to the speakers of languages having subordinate status is one of indifference, avoidance and disparagement. In situations where interdependencies are charted the attitude is one of conviviality. The attitude of indifference can be studied in five parameters:

(a) condescension—the minority language speakers are treated as children;
(b) foreign talk—the distance and superiority of speakers is sunk in others through slow and loud talk;
(c) terminologies—deficient and non-ambitious use mark the relative lowliness of the other language;
(d) distinct accents—carefully cultivated distinct accents mark the superiority of the dominant language speakers;
(e) pretense of identification—occasional use of lexical or suprasegmental features of the minority language heightens the distance.

The attitude of avoidance similarly can be studied under five parameters:

(a) the direct characteristics are emphasized to distinguish oneself;
(b) specific phonological characteristics are deleted or added;
(c) high powered abstractions, professional jargon and technical terminology are added;

(d) 'you people' as distinguished from 'I/we' is used;
(e) pretence of non-understanding, signal avoidance.

The attitude of disparagement can also be studied in terms of five parameters:

(a) use of derogatory terms and epithets towards 'other' languages;
(b) use of ethnic jokes and humor while referring to 'other' languages;
(c) use of hyberbolic descriptions and even four-letter rhetoric about 'other' languages;
(d) use of one's own language with complete disregard to its impact on the situation;
(e) imitation (parody) of the 'other' language to signal disparagement.

All the above three attitudes reflect the intent of the speaker, who is convinced of the richness and superiority of his or her language over others. They also reflect his or her uneasiness with many languages.

5. Conflict of Language(s) of Wider Communication with the Local as well as National Languages

The conflict between the language of wider communication and national language on the one hand, and local languages on the other, has been viewed variously by scholars. According to Fishman, language of wider communication leads to the development of nationism whereas a national language leads to the development of nationalism. Whether the language of wider communication (LWC) is perceived as neutral and equally inconvenient to all the encompassing languages or a unifying force which stops competition among contending languages to be dominant, the fact remains that there are elements inherent in the context of its use which could be manipulated to generate conflict. Whether it is Kiswahili in Africa or Nagamese and Sadri in India being LWCs among mutually unintelligible divergent languages, they by and large serve the interest of the elites. Local elites created in the process come into conflict with the masses of the population speaking different languages as well as with those who use dominant national languages. The absorption of the LWC in the national language depends on the density of communication between the two and the assumption of LWC functions by the national language.

5.1 Conflict Arising from Use, Disuse and Misuse of Languages in Different Domains

Sindhi is one of the Indian languages for the maintenance of which there is considerable political demand, but in reality Sindhi parents prefer Hindi-medium education for their children. Use and disuse of language can thus be a major source of conflict. In Wales, the Welsh identity assertion movement is a

protest against Anglicization. In Quebec, the French–English controversy is well known for its acrimony. The misuse of a language by way of its imposition over another is the cause of conflict. In Karnataka in India, where 64 percent of the population speak Kannada as a mother tongue, Kannada was declared the first language of every child in the State. Thanks to the resistance of the minority, this declaration has been stayed. The conflict is the result of the misuse of the majority right of the Kannada language.

6. Conclusion

Language is a symbol as well as an instrument. It is a repository of power. An expression of identity as well as associate of ethnicity it is a source of conflict. Language differences reflect social tensions. When these tensions are socially or politically manipulated, conflict ensues. Intra-group convergences and inter-group distances give rise to conflicting situations. Integration can be through structural incorporation of differences rather than through assimilation. Conflicting situations can be resolved by compromise.

Linguicide

T. Skutnabb-Kangas and R. Phillipson

1. Definition

A taxonomy of policies, which a state can adopt towards minority languages (Cobarrubias 1983: 71) distinguishes between the following:

   (a) attempting to obliterate a language;
   (b) letting a language die;
   (c) unsupported coexistence;
   (d) partial support of specific language functions;
   (e) adoption as an official language.

The first policy is overtly linguicidal, the second and third may be covertly linguicidal. Linguicidal policies have at times been overt, for instance US policy in

567

Pacific islands such as Guam in the early twentieth century (Kloss 1977). Calvet (1974) describes French colonial overtly linguicidal policy as *glottophagie* ('linguistic cannibalism'), dominant languages replacing and extinguishing dominated languages and as *la guerre des langues*, ('linguistic warfare') in 1987. The latter title seems less a metaphor and more the reality of the politics of language and relations between languages (see Mateene 1985, Phillipson 1992, for further analyses).

Linguicide or linguistic genocide is the extermination of languages, an analogous concept to physical genocide, whereas language death is the withering away of languages, by analogy with natural death (see *Language Maintenance, Shift, and Death*). Linguicide, by contrast, implies that there is an agent involved in causing the death of languages. The agent can be active ('attempting to obliterate a language') or passive ('letting a language die,' or 'unsupported coexistence'), also often leading to the death of minority languages. In liberal ideology, only an active agent with the intention to kill languages would cause linguicide, whereas the other two would fall within the domain of language death. Linguicide is the extreme end result of linguicism (linguistically argued racism) at group level. Seen from the perspective of a conflict paradigm, the causes of linguicide and linguicism (see *Linguistic Imperialism*; *Discrimination and Minority Languages*) have to be analyzed from both structural and ideological angles, covering the struggle for structural power and material resources, and the legitimization, effectuation, and reproduction of the unequal division of power and resources between groups based on language. The agents of linguicide/linguicism can also be structural (a state, e.g., Turkey vis-à-vis Kurds; an institution, e.g., schools; laws and regulations—e.g., those covering linguistic rights or the position of different languages on time-tables in schools; budgets—e.g., for teacher training or materials in certain languages) or ideological (norms and values ascribed to different languages and their speakers). There is thus nothing 'natural' in language death. Languages cannot be treated in an anthropomorphic way, as organisms with a natural life span. Language death has causes, which can be identified and analyzed.

When the United Nations did preparatory work for what was to become the *International Convention for the Prevention and Punishment of the Crime of Genocide* (E 793, 1948), linguistic and cultural genocide were discussed alongside physical genocide, and were seen as serious crimes against humanity. When the Convention was accepted, Article 3, which covered linguistic and cultural genocide, was voted down and is thus not included in the final Convention of 1948 (see Capotorti 1979: 37). What remains, however, is a definition of linguistic genocide (in Art.

3, 1) as: prohibiting the use of the language of the group in daily intercourse or in schools, or the printing and circulation of publications in the language of the group.

But the present Convention has two definitions of genocide which describe most indigenous and minority education in the world:

Article II(e), 'forcibly transferring children of the group to another group'; and

Article II(b), 'causing serious bodily *or mental* harm to members of the group' (emphasis added).

2. Language Loss

First language attrition and loss have been described fairly extensively in research literature and fiction. Kouritzin (1999) describes many cases in Canada where immigrant minority children have lost a language within one generation so that they as adults, for instance, are no longer able to speak to their parents in that language. Wong Fillmore (1991) has described the consequences for families in the USA. Mühlhäusler (1996) discusses results of linguistic imperialism in the Pacific. Janulf (1998) shows in her longitudinal study that of those Finnish immigrant minority members in Sweden who had Swedish-medium education, not one spoke any Finnish to their own children. Even if they themselves might not have forgotten their Finnish completely, their children were certainly forcibly transferred to the majority group, at least linguistically. This happens to millions of speakers of threatened languages all over the world. For hearing minority students, education through the medium of a dominant majority language often leads to the students using the dominant language with their own children later on. Over a generation or two the children are linguistically and often also culturally assimilated, forcibly transferred to a dominant group. Since there are no alternatives in formal education (i.e., schools or classes that teach mainly through the medium of the threatened indigenous or minority languages), the transfer happens by force. For it to be voluntary, alternatives should exist, and parents would need to have enough reliable information about the long-term consequences of the various choices. None of these conditions are usually fulfilled for indigenous or minority parents and children, i.e., the situations where children lose their first language, can often be characterized as genocide.

Since most deaf children are born to hearing parents, parents and children do not have the same mother tongue by origin, and many of the deaf children will in their turn have hearing children. Deaf children of hearing parents are in many countries still taught through oral methods, i.e., taught lip-reading and speaking in a dominant majority language, to the exclusion of a sign language. They are not learning their 'own' language, a sign language, which is for all

deaf children the only type of language through which they can express themselves fully, i.e., it is their mother tongue by competence. Thus both hearing indigenous and minority children and deaf children, taught predominantly through the medium of a dominant oral majority language, are undergoing linguistic genocide: both groups of children are forcibly transferred from their 'own' language group to dominant majority language group (see *Sociolinguistics of Sign Language*).

Some countries commit linguistic genocide openly and brutally, and Turkey is the most blatant example in the contemporary world (see Skutnabb-Kangas and Bucak 1994): imprisonment, torture, and killing of thousands of people, in addition to threats, hefty fines and confiscation of Kurdish books, journals, and property. But linguistic genocide is today mostly committed in more covert and sophisticated ways, e.g., in educational systems. Here the use of a minority language is prohibited more indirectly, by ideological and structural means. The use of a minority language is in fact prohibited 'in daily intercourse or in schools' every time there are minority children in daycare centers and schools, but no bilingual caretakers and teachers who are authorized to use the languages of the minority children as the main languages of teaching and learning in child care, and at least primary education. This is the situation for most immigrant and refugee minority children in all Western European countries and in the US, Canada, and Australia. Immigrant minority education in these countries is thus the main cause of linguistic genocide, as defined by the UN. So is the education offered to most indigenous first nations, and to numerically large but politically dominated groups in most African and many Asian countries (see Skutnabb-Kangas 2000 and Brock-Utne 1999 for Africa). Dominant or majority languages expand at the expense of dominated (or minorized) languages when minority language speakers are forced to learn dominant languages in a *subtractive* way (instead/at the cost of their own languages), where it would be perfectly possible to learn them in an *additive* way, adding competence in dominant languages to maintenance and further development of their own languages (see *Bilingualism, Societal*).

Linguists estimate that up to 90 percent of today's oral languages (and most sign languages) may not exist in the year 2100 (Krauss 1992). Binding linguistic human rights are urgently needed to prevent linguicide. The UN, UNESCO, ILO (International Labor Organization), OSCE (Organisation for Security and Cooperation in Europe), OAU, Council of Europe, etc. have been concerned about the 'endangered languages' of indigenous peoples and linguistic minorities, but existing international, regional and national protection and support are clearly completely inadequate. Several book-length presentations of language rights have appeared in tandem with the increasing salience of language issues and ethnicity in many post-communist and post-colonial trouble spots. (Only a few are cited here: e.g., Benson et al. 1998, Guillorel and Koubi 1999, Kibbee 1998, Kontra et al. 1999, Phillipson 2000, Skutnabb-Kangas 2000). Subtractive learning of dominant languages turns these into killer languages, whereas additive learning would support the maintenance of linguistic diversity. Widespread linguicide and language death are fatal for linguistic diversity and, through that, also to biodiversity on earth (Harmon in press, Maffi 2001, Maffi et al. 1999). Through linguicide, we are also in the long run seriously undermining the prerequisites for life on the planet.

Linguistic Imperialism

R. Phillipson and T. Skutnabb-Kangas

The study of linguistic imperialism focuses on how and why certain languages dominate internationally (become 'world languages'), and attempts to account for such dominance in an explicit, theoretically founded way. The same type of processes can also be at work internally in a country, making some languages dominate over others.

In recent centuries the languages of European settlers and colonists have been taken to all continents, and many of them have remained there. Language is one of the most durable legacies of the age of imperial expansion. Thus in Africa the languages of the colonizing powers (France, UK, The Netherlands, and Portugal) were more firmly entrenched in the late twentieth century than they were in the colonial period; on the Indian subcontinent, English is still the language of power. Spanish and Portuguese are the dominant languages of Latin America.

Such facts about the contemporary world raise many questions that the study of linguistic imperialism can help clarify. Has the winning of political independence led to a linguistic liberation in Third World, underdeveloped (Rodney 1972) countries, and if not, why not? Are the former colonial languages a useful bond with the international community and necessary for state formation and national unity internally? Or are they a bridgehead for Western interests, permitting the continuation of a global system of marginalization and exploitation? What is the relationship between linguistic dependence (continued use of a European language in a former colony) and economic dependence (the export of raw materials and import of technology, knowhow, etc.)?

1. The Nature of Linguistic Imperialism

Imperialism theory has traditionally (Hobson 1902, Lenin 1973) been primarily concerned with economic and political aspects of dominance. More recent theorists have been concerned with the whole range of activities, structures, and ideologies which link powerful countries, the 'Center,' with powerless countries, the 'Periphery.' As a result such dimensions as military, social, communication, and cultural imperialism have been added to economic and political imperialism (e.g., Galtung 1980). All the constituents are seen as contributing to the maintenance of a structure of exploitation from which rich countries benefit, and poor countries suffer. Resources are also distributed unequally internally within each country, which has its own Center and Periphery.

Each type of imperialism interlocks with the others in mutually reinforcing ways. Linguistic imperialism therefore presupposes an overarching structure of asymmetrical, unequal exchange, where language dominance dovetails with economic, political, and other types of dominance.

Linguistic imperialism can be regarded as a subcategory of cultural imperialism. Other subcategories are media imperialism (e.g., news agencies, the world information order), educational imperialism (e.g., the export of Western institutional norms, educational systems, teacher training, textbooks, etc.), scientific imperialism (e.g., dissemination of paradigms and methodologies from the Center, which controls knowledge about the Periphery). Linguistic imperialism may closely dovetail with media, educational, or scientific imperialism. It is almost certainly the language of the dominant power

which is used as the medium of communication in each of these domains of cultural imperialism, just as it is in other areas, e.g., political, economic, etc., not only in international relations but also internally. This gives the dominant language and the learning of it as a second or foreign language a crucial role in the mediation and in the reproduction of an asymmetrical relationship.

Imperialism theories attempt to link the various types of imperialism in a principled way, so as to account for the connections between one factor, for instance language, and others operating in conjunction with it, for instance military conquest (which almost invariably accompanies colonial occupation) or religion—consider the spread of Spanish and Catholicism; or analogies and contrasts between this and the spread of Arabic and Islam; or the role of missionaries in alphabetizing indigenous languages in Africa, Asia, and Latin America, e.g., the work of the Summer Institute of Linguistics (see *Missionaries and Language*).

2. Creation of Beliefs and Structures to Sustain Linguistic Dominance

Language is frequently involved in the maintenance of relations of dominance. The maintenance of a hierarchical relationship usually involves a pattern of stigmatization of dominated languages, glorification of the dominant language, and rationalization of the relationship between the languages, always to the benefit of the dominant one. Thus the Greeks stigmatized non-Greek speakers as 'barbarians' (speakers of mumbo-jumbo, a non-language). The 'Welsh' were foreigners, people who spoke a 'strange language' that 'one does not understand' (cited in the Oxford English Dictionary, 1648). The languages of colonized people were categorized as 'primitive,' mere 'patois.' 'Local languages' in France are characterized by an 'incapacity to serve beyond their limited frameworks' and their speakers have 'difficulties in adapting them to the development of ideas and techniques' (a French Government assessment, quoted in Capotorti 1979: 13) (see *Dialect and Dialectology*).

One's own language, on the other hand, was glorified as the language of God (Arabic, Dutch, Sanskrit), the language of reason, logic, and human rights (French in recent centuries), the language of the superior ethno–national group (German in Nazi ideology), the language of modernity, technological progress, and national unity (English in much postcolonial discourse), etc. The speakers of stigmatized languages can therefore only benefit from using the 'superior' languages. Such beliefs serve to legitimize the linguistic and social hierarchy (see *Power and Language*).

But linguistic imperialism is not just a question of labels, attitudes, and beliefs. It presupposes a structure regulating social and institutional power. In an imperialist structure one society or collectivity exploits another, e.g., Europeans taking their languages worldwide, to the detriment of the cultures and languages of native peoples in the Americas, Australasia, etc. 'Internal' colonization of this kind can also be regarded as imperialist. Second, structural dominance is asserted through the allocation of more material resources to one language rather than another, and via regulations and practices that stipulate that one language rather than another should be used. This structure explains why, for instance, English has thrived while the other languages of the UK have been marginalized. In France this hierarchical and linguicidal model has been official policy since the sixteenth century (see *Linguicide*). The edicts of the French Revolution were initially disseminated in the many languages spoken in France, but from the early 1790s the message of 'freedom, fraternity and equality' was propagated through the exclusive medium of French. The monolingual ideal associated with the 'modern' state has been exported worldwide.

One difference between French and British colonial policy was that the indigenous languages were seldom used in education in the French empire, whereas they were widely used in the British empire in the initial years of schooling. However, local languages invariably had low status, and it was the colonizers' language which provided access to power and resources. The linguistic hierarchy was thus comparable in each empire. This is also borne out by what has happened since the 'independence' of countries from each empire: the former colonial languages remain as the dominant languages, to the advantage of those who can use them, while indigenous languages remain, with few exceptions, marginalized. Gilbert Ansre, the Ghanaian sociolinguist, describes linguistic imperialism as:

> the phenomenon in which the minds and lives of the speakers of a language are dominated by another language to the point where they believe that they can and should use only that foreign language when it comes to transactions dealing with the more advanced aspects of life such as education, philosophy, literature, governments, the administration of justice, etc. ... Linguistic imperialism has a subtle way of warping the minds, attitudes and aspirations of even the most noble in a society and of preventing him from appreciating and realising the full potentialities of the indigenous languages (1979: 12).

As a result of linguistic imperialism, the vast majority of languages in former colonies have not gone through the processes of development which most European languages have experienced in recent centuries. Their growth and expansion has been kept in check by the presence of the former colonial

languages, and the vested interests, national and international, associated with these (on African languages, see Mateene 1985. Ngũgĩ 1986; on India, Pattanayak 1986, on the Pacific region, Mühlhäusler 1996). 'Aid' in the language and education field has contributed to impeding the elaboration of local solutions to meet local problems. When the former colonial languages have been used as the medium of education in schooling, the gulf between the ruling class and ordinary people has been widened. However, there is an increasing awareness that such aid was culturally and educationally flawed: for a Ford Foundation analysis describing the failings of their projects, see Fox 1975; on the inappropriateness of Western training in linguistics for Third World language management purposes, see Jernudd 1981; on ethnocentric, unscientific tenets in applied linguistics and English language teaching, see Phillipson 1992.

As many scholars from the 'underdeveloped' world have pointed out, the arguments used to justify the continued use of European languages in such contexts are quite false and neglect the educational, cultural, and linguistic realities and needs of all except the elites (who are the ones with strong links with Center countries, having often been educated there or through the medium of the Center language). Just as the economies of countries in the Periphery have been underdeveloped through their subordination to the economies of the Center countries, their languages have also been underdeveloped. Linguistic underdevelopment occurs whenever these languages are not used for the full range of societal functions that Ansre lists, with these functions being reserved for a supposedly 'superior,' Western language. This situation even still holds in countries which have made substantial efforts to promote a local language. In Tanzania there is a triglossic (see *Diglossia*) situation, English being 'high' vis-à-vis Swahili, and Swahili 'high' vis-à-vis the other indigenous languages.

3. Promotion of Dominant Languages

Language plays a vital role in international contexts. This role has become ever more important as brute physical force (conquest, occupation) has given way to subtler types of control. Language not only mediates links (in the media, business, military, etc.); it is itself an object of cultural dissemination. The 'Alliance Française' has been promoting knowledge of the French language outside France for over a century. Many other Western European nations run similar, state-supported operations, as does Japan. Saudi Arabia provides substantial financial aid for the teaching of Arabic in underdeveloped countries. The rise of English as the international language par excellence of the postwar period has not been left to chance. It has been declared government

policy on both sides of the Atlantic to promote English worldwide, and simultaneously to curb the extension of possible competitor languages, whether the Cold War enemy's language, Russian, other Western European languages, or the languages of newly independent countries, Arabic, Hindi, etc. In the words of a director of the Center for Applied Linguistics in Washington DC:

> From a minor language in 1600, English has in less than four centuries come to be the leading language of international communication in the world today. This remarkable development is ultimately the result of seventeenth, eighteenth, and nineteenth century British successes in conquest, colonization, and trade, but it was enormously accelerated by the emergence of the USA as the major military world power and technological leader in the aftermath of World War II. The process was also greatly abetted by the expenditure of large amounts of government and private foundation funds in the period 1950–70, perhaps the most ever spent in history in support of the propagation of a language. (Troike 1977: 2)

The expenditure has gone toward the establishment of professional infrastructure (specialist university departments, institution building, teacher training, curriculum and textbook development, etc.) in the Center and the Periphery. There have been close links between the academic world, government (or paragovernmental agencies such as the British Council), and publishing houses. The role of American 'philanthropic' foundations in promoting worldwide cultural links has been well analyzed (see Arnove 1982). The Center for Applied Linguistics in Washington DC, was established with Ford Foundation funds. Ford had language and education projects in over 30 countries in the 1960s and 1970s, a decisive period in the transition from colonialism to the contemporary, neocolonial phase. The British Council has a substantial number of language experts scattered over the world, many of them in advisory or catalyst, 'multiplier' roles rather than as classroom teachers. Such government-financed language activities are designed to create dependence on the dominant language in order to further its use for those purposes which the language otherwise serves, generally in a structure of linguistic imperialism.

4. Approaches to Linguistic Dominance

There are many academic specializations with concerns which are close to those of linguistic imperialism: language planning, the sociology of language, sociolinguistics, and applied linguistics. However, these disciplines have tended to shy away from directly confronting the issue of the power of languages internationally. Even from a country-internal perspective, little work has been done to develop a unifying theory of linguistic inequality, despite the extensive documentation of pervasive

linguistic inequality worldwide (for instance studies of language attrition and death, of language revival, of postcolonial education policy). Work in the field of 'language spread' (see Phillipson in press) is often strong on identifying and quantifying factors involved in language spread, but tends to be relatively weak in analyzing causal, structural factors.

Slavery and colonization were imposed by physical violence and legitimated with reference to primitive biologically-based racism. In the contemporary world the physical violence of the stick, associated with crude racism, has given way to psychological violence. To capture this phenomenon and account for the way language is used as a means of hierarchizing, in similar ways to racism and sexism, the concept 'linguicism' has been coined (Skutnabb-Kangas 1988). Linguicism is defined as 'ideologies, structures, and practices which are used to legitimate, effectuate and reproduce an unequal division of power and resources (both material and non-material) between groups which are defined on the basis of language.' The concept has been used in the study of minority education (ibid.), and in a study of the spread of English as a 'world' language and the specific contribution of applied linguists and English language teaching 'experts' in facilitating this spread (Phillipson 1992).

Linguicism facilitates the control of dominated groups by means of carrots rather than sticks, ideas rather than threats. When benefits accrue only to those who learn and use a dominant language, and when shame and guilt are inculcated in those who use a stigmatized, dominated language, the oppressive structure and linguicist ideology are likely to be internalized. It then appears to be in the interest of speakers of dominated languages to shift language. This has been the reality of most indigenous and immigrant minorities in Europe and Europeanized countries.

The expansion of English in colonial and post-colonial periods has also been analyzed in terms of the discourses of cultural politics (Pennycook 1994). Analysis of contemporary English in a wide range of countries in British and American spheres of influence leads Fishman et al. to see the need for English to be 'reconceptualized, from being an imperialist tool to being a multinational tool ... English ... being post-imperial (as the title of our book implies, that is in the sense of not directly serving purely Anglo-American territorial, economic, or cultural expansion) without being post-capitalist in any way' (1996: 8). Fishman et al. regard the continued strength of English as being determined locally and voluntarily in such countries, but this underestimates the way a western-dominated globalization agenda is being implemented by the transnational corporations, the World Bank, the IMF, and

the World Trade Organization. English is being strengthened through regional trading alliances, such as the North American Free Trade Agreement and the European Union. English is increasingly used in EU institutions and member states, despite a great deal of EU rhetoric proclaiming the wish to maintain linguistic diversity. It is arguable that new forms of linguistic imperialism worldwide (in the media, military, political, scientific and educational worlds, youth culture, etc.) mean that English represents a threat to all other languages, though the analysis of the interlocking of English with processes of globalization and localization is still in its infancy (Phillipson 2000).

Manipulation

N. Fairclough

The strategies that people use to get others to do what they want them to do are partly linguistic, involving manipulative uses of language. 'Linguistic manipulation' is the conscious use of language in a devious way to control others (see *Power and Language*), where 'using language in a devious way' means using it in a way which hides one's strategies and objectives. This happens quite commonly in conversation; for example, saying how busy or how tired one is can be a devious way of getting out of a responsibility or commitment. In such cases, linguistic manipulation involves the use of 'indirect speech acts' (see *Speech Act Theory: Overview*) which are oriented more to the 'perlocutionary' effects of what is said (what it allows the speaker to achieve) than to the apparent 'illocutionary' acts that are performed (claiming to be busy, expressing tiredness) (see *Pragmatics and Socio-linguistics*). Of course, attempts at linguistic manipulation are not always successful; people become adept to a greater or lesser degree at 'seeing through' what is said.

There are various institutional domains in which manipulative discourse (see *Discourse*) is systematically used and indeed expected, such as police interrogations of suspects, or cross-examination of witnesses in a court of law. In the latter case, for example, cross-examining counsel may try to linguistically manipulate both the witness and the jury. The manipulation of witnesses involves counsel exploiting their control over the interaction by strategically constructing sequences of questions designed to gradually build up evidence and lead to accusations. The manipulation of juries includes various devices for suggesting that a witness's testimony is not to be trusted, such as forcefully repeating a question after the witness has answered it, or showing disbelief through a combination of intonation and facial expression.

Linguistic manipulation is also a feature of political rhetoric (see *Politics and Language*). Political discourse is in the business of persuasion, be it persuading people to take political action or persuading people to support a party or individual, and recourse to devious means is not uncommon. In modern societies, politics is largely conducted through the mass media (see *Media Language and Communication*), and this leads to new forms of linguistic manipulation; political organizations put a great deal of effort into press conference and press statements, and into constructing slogans and catch phrases in ways that make them likely to be adopted by the media. One aspect of manipulation in political discourse that has received extensive attention is the exploitation of the connotative meanings of words. For example, in attempts by the most powerful countries of 'the West' to exercise political hegemony over smaller countries, a widely used device in the late twentieth century has been accusing governments and other groups of supporting or being 'soft on' terrorism. Political discourse also makes extensive use of the persuasive potential of repetition and grammatical parallelism (e.g., *We don't want the poll tax to be reviewed, we don't want the poll tax to be reduced, we want the poll tax to be abolished!*). Rhetoric is of course not exclusively used in political discourse; some research has shown, for example, how articles in scientific journals use rhetorical devices to convince readers.

Advertising (see *Advertising*) uses a combination of language and visual imagery to get people to buy particular products or, increasingly, to give people a positive image of an individual, organization, or service. Although the motives of advertisers are clear to most people, linguistic manipulation on a grand scale is used to achieve them. Words and images are used to jointly construct imaginary or heavily idealized worlds or 'lifestyles' which people can imagine themselves a part of. This often gives the manipulatory language of advertising a pseudo-poetic quality (e.g., from an advertisement for sanitary towels, *I came back. I came back to softness and comfort. I came back to Dr White's.*).

A feature of the late twentieth-century socio-linguistic order in Britain and various other countries is a process of 'technologization of discourse,' wherein discourse practices are systematically subjected to research and redesign, the results of which are incorporated in the training of various types of institutional personnel. Consider interviewing as an example. A great deal of research has been carried out on interviewing practices in institutional contexts (different types of research interview, job interview, disciplinary interview, etc.), which has led to recommendations for redesigning interviews to make them more effective in one way or another, and to the training of institutional personnel in interview techniques. Experts in relevant branches of social scientific research (especially in psychology) are being brought into organizations to carry out such work on a systematic basis. The same sort of expertise is being seen as relevant to widely divergent institutional contexts, and techniques like interviews are coming to be defined in universal and context-free ways, as transferable skills which are in principle useable anywhere. This implies the colonization of institutional orders of discourse by culturally salient practices, and a standardization of practices across institutions. Technologization of discourse is rather different from the forms of linguistic manipulation discussed above. But it can be regarded as an indirect, mediated form of linguistic manipulation: in so far as it succeeds in reshaping discourse practices, it can surreptitiously bring the behavior of whole groups of people under control.

However, those who use practices such as interviewing which have been redesigned in this way are not necessarily or even usually using them manipulatively. Members of professional groups such as doctors, teachers, or personnel officers acquire interviewing techniques as part of their professional training, and may normally use them as a matter of common sense without any manipulative intent. Such techniques do contribute to controlling people, but they do so because of the ways in which they are ideologically invested (see *Power and Language*) rather than necessarily with manipulative intent, and they control all those who use them (interviewers as well as interviewees in this example).

Marxist Theories of Language
G. Mininni

The hinges of a Marxist consideration concern the links binding the language to the structure of society, to models of material praxis, and to forms of ideology. An evaluation of relationship between Marxism and the sciences of language coincides with the overall judgment expressed by many scholars on the historical experience of the so-called 'real socialism': the questions on the agenda are relevant and unavoidable, but the answers given are, on the whole, misleading or disappointing. The questions posed by Marxism as an interpretive methodology of social relationships may be worded as follows: which linguistic arguments prove that 'man is the sum of social relationships?' How are the different systems of beliefs, socially shared knowledge, cultural values, and rules of a human community continuously rebuilt in his language? How do the ideal–typical needs for mutual understanding and the real contingencies of differentiation and social struggle weave together in the language? These queries question all the symbolic articulations connected with the difference between manual labor and intellectual work.

1. Looking for a 'True' Marxism in Linguistics

What is the meaning of 'being a Marxist in linguistics?' First of all, it must be stressed that from a methodological point of view, it is not a question of applying Marxism to linguistics (Ponzio 1989), as such an approach carries the idea of a 'will of power' which is not acceptable for cultural practices guided by the paradigm of the search for a historical, consensual truth. Any attempt at a mere external application legitimates a defense mechanism aiming at protecting the autonomy of language science against the obtrusiveness of ideological knowledge. To adhere to a Marxist theory of the language does not mean to draw the proposals of a linguistic explanation from the dogmas of social philosophy, but to identify a route of interpenetration between the problems posed by linguistic practice (or meditation) and the possibilities of an unbiased analysis of

the same at a social level, just like the one Marx carried out to explain how the capitalist economy of his time worked.

1.1. Classics' Indications

The hypothesis of a direct accessibility between Marxism and language sciences may seem surprising when one considers that the assertions concerning language are poor and fragmentary in the classical literature of Marxism. Some passages from *The German Ideology* are extremely enlightening, especially those where Marx and Engels (1970) explain that language originated from the need for relationships with others, and is the matter that from the beginning 'contaminates' the spirituality of a 'real, practical conscience' which is typical of man. Other noteworthy references can be found in the section about *Nature's Dialectic*; here Engels develops Darwin's theme of the ape's humanization processes and suggests the existence of a strict connection between language and work. Of course, from an early date (Lafargue 1936), scholars' attention was attracted by the possibility of identifying a class-prejudiced characterization both in the use of language and in the process of its historical evolution. This assumption does not justify in the least the absurd contraposition of a 'socialist' or 'revolutionary linguistics' to a 'capitalist' or 'reactionary one,' which would necessarily occur if Marxist theoretical and ideological principles were schematically applied in a scientific investigation of linguistic problems.

1.2 Scylla and Charybdis in Marxist Linguistics

A subtle plot of historical and political conditions led Joseph V. Stalin to denounce the fact that Nikolai J. Marr (the recognized spokesman of Marxist theory in linguistics until then) had incurred such an aberration in his doctrine, as he had reconciled his own monogenetic (or Japhetic) hypothesis of language with assertions about its superstructural and class prejudiced nature. The great normalizer of the Soviet State often intervened in the linguists' debate published in *Pravda* (summer 1950), and—as an expert on Marxism, not on glottology—he presumed to outline the correct picture of a Marxist interpretation for linguistic questions. Stalin's position—which seems to be supported by common sense and is consistent with the scientific programs of Saussure's structuralism and Durkheim's sociology—turns out to be fundamentally incorrect both in its method and in substance, although it is absolutely justified by virtue of a certain sociolinguistic policy. As a matter of fact, on the one hand, the pretension to solve a scientific debate by a substantial appeal to authority appears unacceptable; on the other hand, the rebuttal of Marr's thesis is carried out with the help of trivializing arguments. However, from the point of view of the history of thought, Stalin's intervention is

an affirmation and, at the same time, a denial of a Marxist theory on language. It is an affirmation because it demonstrates *de facto* that any theoretical language elaboration is bound by reasons of social and political practice. Language sciences, too, obey precise constraints deriving from the development of human relationships and draw inspiration from the ideological climate in which a society lives. Actually Stalin's concern to preserve languages conceals the 'sovietization' process imposed on the different nationalities gathered in the former USSR, and aims at defusing social conflicts. But Stalin's position patently clashes with that dimension of Marxist theory, so it necessarily adheres to a 'critical linguistics,' that is to say, a linguistics which tries to unveil the dominant mechanisms operating in communicative practices. For a number of reasons, Stalin could not adopt such a view, and in order to avoid the problems that Marr had reasonably posed but incorrectly solved (Borbé 1974), he takes refuge in an attitude of denial: as a language system has its own autonomous organization and is an instrument of national identification, language is not a superstructure, and does not have a class character; so Marrism is not the equivalent of Marxism in linguistics. Stalin's position is not only mistaken, as he commits the 'minimalist error' (Mey 1978) of considering language as a mere by-product of the cultural life of a nation, but it is also responsible for putting an end to the debate on the potential of Marxism in linguistics, through its own mystification (Marcellesi and Gardin 1974).

2. Language Sciences and Critique of Ideologies

If we escape both monsters of Marrism and Stalinism, are there other implemented models of interpenetration or mutual control between the social theory of Marxism and linguistic questions?

2.1 'Bakhtin's Circle'

In fact, an authentically Marxist position in the language sciences is worked out in the post-revolution decade in Russia by the so called 'Leningrad School.' Mikhail M. Bakhtin (see *Bakhtin, Mikhail M.*), Valentin N. Voloshinov (see *Voloshinov, Valentin Nikolavic*) and Pavel N. Medvedev try to develop a semiotic theory of culture based on Marxist principles. Their conceptual pattern sets three interpretative routes: decoding psychic processes both historically and socially; exploring the polyphonic dialogics (see *Dialogism*) intrinsic in a language; identifying the sociological constraints of a literary text. The Marxist relevance criterion of such an approach is the criticism of the forms of ideology and the way ideology works. In Voloshinov's opinion (1973), a Marxist conception of the problems posed by language philosophy is warranted by the need to explore the sign nature of ideological phenomena. As

a result, the study of the ideologies embodied in the ethical, religious, juridical political, and literary institutions of a society must be based on an explanation of the principles regulating their constitutive elements: i.e., signs. The identification of the ideological sphere with semiotics enables us to explain the formation of an individual conscience as a socio-ideological phenomenon; one must therefore imagine an unseizable dialectic interaction between the mind's working and the activation of sign-ideological systems. The specifically psychological aspects of such an explanatory route were developed by Lev S. Vygotsky; his theory advocates that superior psychic processes (memory, language, will, etc.) are interiorizations of social interactions mediated by signs. To explain the connection between language and ideology, Voloshinov resorts to a metaprocedural strategy: he shows which ideologies are carried by linguists. Two macrotrends are therefore identified in the study of language, which appear as epistemological constants and are still in force: individualist subjectivism (from Humboldt to Croce and Vossler) and abstract objectivism (which was exemplarily represented by Saussure). Voloshinov demonstrates that the Marxist point of view calls for an analysis of the socio-ideological material 'molded' by verbal interaction in order to rebut both the unsubstantiality of individual creativity in linguistic expression and the narrow-mindedness of a superindividual system of rules escaping the manifold pressures of language usage.

2.2. Social Cognition and Linguistic Praxis

The debate interrupted by Stalin and the programs started by the 'Leningrad School' were reconsidered in the 1960s both by Soviet scholars who were interested in giving a historical and materialist direction to semiotic structuralism (Reznikov 1964), and by other scholars working in the field of social criticism in the capitalist West (Cornforth 1965). An interesting bridge between these two perspectives had been anticipated in Italy by Antonio Gramsci's brilliant intuitions (see *Hegemony*), and was later consolidated by Adam Schaff (1967). The need for 'Marxist linguistics' was set by the Polish philosopher in the sphere of a knowledge theory beyond the opposite extremes of mechanistic materialism and subjective idealism. According to Schaff, a Marxist theory emphasizes the role of mediating procedure that language plays between what is subjective and objective, mental and social, biological and cultural. This theory acts as a central support for a conception of man as the being who is responsible for the creation of his own cognitive and relational models. Even if some differences can be found from the point of view of inner logic as well as on the level of philogenetic and ontogenetic acquisition, the process

of 'thinking–speaking' is substantially unitary, as cognition is an effect of social praxis and communicative relations are full of cognitive contents. This dialectic unity enables us to reject both the reflex theory suggested by a naïve materialism and the theory of significant systems autonomy, proposed by some updated versions of idealism. Furthermore, Schaff's Marxist language theory aims at being immediately employed in the practical questions weighing on the decision-making ability of a human person as an actor and a maker of his/her social world. On this subject, Schaff also considers a social categorization process which emphasizes the connection between ideology and language, that is 'thinking–speaking by stereotypes.' The resort to stereotype and to prejudices gives emphasis to the fact that as the relationship between the individual mind and reality is mediated by the sphere of meanings, the workings of the mind itself are influenced by historical and social conditionings. Stereotypes reveal the real control that social groups have over the contents and processes of individual thought. Schaff's pragmatic point of view allowed him to give stereotypes of that socio-integrative and defense function which makes them compatible with the political structure of society. Similar conclusions are drawn by all those currents of sociolinguistics and pragmalinguistics that wonder about the connections between the conscience of sociality carried by the language and the limits of what the historical conditions of praxis allow human subjects to mean when they are diversified by factors such as age, sex, culture, class, degree of social control, etc. Some theories within 'social linguistics' are marked by an implicit adhesion to a Marxian inspiration, such as 'praxematics,' coming from Lafont's school or Mey's pragmatic approach. Lafont (1978) works out a linguistics focused on the 'praxeme': this is an instrument for the production of sense in speech and, at the same time, a unit of analysis in the relation between the language user and the practical social conditions which make it possible for the uses of linguistic varieties to clash. In outlining the basic question 'Whose language?,' Mey (1985) makes a constant, critical comparison between the categories obtainable from analysis of industrial society (such as production, oppression, and manipulation) and the instruments of linguistic analysis. According to Mey, the Marxian inspiration in sociolinguistics lies in the need for a theory which can explain the intricate relationship between language as a sociocultural product and the forms of the overall reproduction of a society. The solution he proposes entrusts pragmatics, as the theory of linguistic use, with the task of explaining the various 'wording' possibilities connected with the clashing nature of groups, with different approaches to knowledge and with different power distributions.

2.3 Sign Systems and Social Reproduction

The principles of historical–dialectical materialism imply that language is interpreted by abstractions which are in turn determined by the sum of practices regulating man's 'organic exchange' with nature, bearing in mind the often distorted representations imposed by the historical limits within which man is obliged to live his social relationships (Erckenbrecht 1973). The Marxist idea of language aims at specifying the features of the production of sense carried out by man in the present circumstances of his history and, therefore, at identifying the role of sign systems within the process of 'social reproduction' as a whole. This category indicates the totality of techniques and procedures through which human groups perpetuate their presence in the world. In this perspective, Ferruccio Rossi-Landi's (1983) tentatively investigated connection between language and work is justified. At first sight, Rossi-Landi seems to exaggerate when he applies the Marxian labor theory of value to the field of language and to other non-verbal forms of human communication. Indeed, the most important thing is the epistemological and methodological indication of the need for passing from the surface level of exchange and/or the sign market to the underlying level of social labor which is implicit in cultural signification and communication processes. This change of focus makes it possible to criticize the dichotomy traditionally accepted by linguists (out of common sense) between the 'system' and 'use' of the language, both in its classical version of Saussure's opposition between 'langue' and 'parole,' and in its neoclassical version of Chomsky's opposition between 'competence' and 'performance.' The adherence to these two categories enables linguists to secure the fetish of an explanatory autonomy, by confining the pertinence of Marxism to the illustration of the social function of a language. On the contrary, in Rossi-Landi's view, those abstractions are useful only if they are rooted in the ground of 'common speaking,' which defines historically the linguistic a priori of the human being. The philosophical methodology of 'common speaking,' which was later generalized in a semiotic methodology of 'common semiosis' by Rossi-Landi, achieves the Marxist theory target of unveiling the ideological consistency of the 'logosphere' and clarifies the mediating role that sign systems play between the economic basis and the superstructures of society.

3. What Shall We Do?

The Marxist perspective, however narrow it may appear, binds those who study linguistic problems to historical–dialectical materialism and obliges them to consider the connections between linguistic theory and the theory of praxis as being relevant. This double bond results in the priority need to explore the linguistic signs' ideological texture. But for the linguist, the adherence to such an explanatory route entails the commitment to carry out his own language investigations according to an emancipatory project concerning the potentials of human beings. To be a Marxist in linguistics means to adopt an intrinsically debunking perspective of the relationships of social control that are formed and/or expressed in the language. Of course, it is not necessary to be a Marxist to work out a critical and emancipatory linguistics, but the opposite is true: it is necessary to take a critical attitude to be authentically Marxist in linguistics. Marxism aims at putting a sort of 'metasemiotics,' meant as a critical theory of ideologies, at the basis of the language sciences. This perspective is shared by those who try to use Marxian categories (class, commodity, labor, surplus value, alienation) in the analysis of the relations of linguistic reproduction in society, and by those who take only a critical stance from Marxism, thinking that this is enough to perfect the technical solutions provided by linguistic knowledge. Both 'revolutionaries' and 'reformers' share the same desire to look for a small red petal in the white cup of meditation on language.

Minority Languages
J. M. Y. Simpson

Various international conferences have been held on the subject of minority languages. For example, the First International Conference on Minority Languages held at Glasgow in 1980 had as its theme 'the present-day problems of minority languages, particularly those of the British Isles, The Netherlands, and Scandinavia.' The questions arise: what is a minority language and what kinds of problems does such a language face? The term presents certain difficulties of definition but it seems safe to say that a minority language will exhibit some at least of the features listed below. The problem can be summed up as the danger of the language becoming extinct.

(a) A minority language lives in the shadow of a culturally dominant language, dominant usually because of political factors, which puts the minority language at risk. Thus Irish, Welsh, and Scottish Gaelic live in the shadow of English; Breton lives in the shadow of French; Frisian in that of Dutch; and Sorbian in that of German. In many cases the absolute number of speakers of the minority language is declining.

(b) As a corollary to the above, a minority language is not the language of all areas of activity indulged in by its speakers. It may, for example, be excluded from formal spheres such as administration, education, or the mass media and may be confined to the home, religious life, or literature. Scottish Gaelic, for example, is (within the Gaelic-speaking area) widely used in church services but only marginally employed in other forms of public gathering, e.g., sports fixtures, political meetings, parent–teacher meetings, etc. It has no part in national government and virtually none in administrative paperwork. It is only modestly represented in the press (yet Scottish Gaelic literature flourishes).

(c) Bilingualism is a characteristic of its speakers. Thus, apart from the very young, there are virtually no monoglot speakers of Irish, Scots Gaelic, or Welsh.

(d) In the case of many minority languages, the speakers may be said to form a network rather than a community. For example, there are no urban centers that could be described as Breton-speaking, Irish-speaking, or Scots Gaelic-speaking.

(e) Because the dominant language is used for discussing certain topics, the minority language may lack areas of vocabulary found in other languages that share the same general culture. Indeed its vocabulary may be influenced by that of the dominant language to the extent of accepting borrowings where native terms exist.

(f) There may be no standardized form of a minority language. There is, for example, no agreed standard for Scots. Similarly, conventions for such things as writing letters may be lacking.

(g) The minority language may be at risk from opponents actively dedicated to its extirpation. An early example of this is the 1616 Education Act passed by the Scottish parliament. This established schools in the every parish with the object of imparting the English vernacular so that Scottish Gaelic, described as the source of all barbarity, should be 'abolisheit and remouvit.' Since knowledge of the dominant language is usually necessary for economic advancement, it may be the case that native speakers will not pass on the minority language to their children.

(h) Because the language may lack areas of vocabulary, or because there is no standard, or because speakers are completely bilingual, there may be reluctance on the part of native speakers to speak the language to learners or even to other native speakers from different dialect areas, on the grounds that differences of dialect present insurmountable barriers to mutual comprehension. Thus the minority language becomes the marker of increasingly small in-groups.

(i) Opponents of the language seize upon gaps in the vocabulary, the absence of a recognized norm, and the reluctance to speak the language to outsiders in order to demonstrate that the language is in some sense 'inferior.'

(j) The cause of a minority language may be taken up by proponents (groups or individuals) dedicated to its preservation or revivial. *Cymdeithas yr Iaith Gymraeg* ('Welsh Language Society'), founded in 1962, and the Scots Language Society, founded in 1972 as the Lallans Society, are two examples.

(k) Efforts to promote minority languages may include language planning or language purification in order to fill the gaps mentioned in (e) above. Thus there are lists of technical vocabulary compiled and published for both Irish and Welsh.

(l) Problems arise in education and official policy varies from country to country: the language

579

may be banned in school; it may be taught as a subject; or it may even be the medium of instruction.

(m) Historical factors may be relevant. The language may not always have been a minority one and it may therefore have possessed at least written norms that it now lacks. Hence a modern writer may incorporate usages from an earlier written language that are no longer found in any spoken variety.

A curious claim sometimes made by proponents of individual minority languages is that they are 'old.' If such a description has any meaning, either it is that the language in question was established in its present location at an early date, or first written down at a relatively early date, or that it represents an alleged earlier state of historical development. It is not clear what any of these interpretations has to do with the value of a language; unfortunately, 'oldness' continually crops up as a kind of guarantee of respectability.

It should be noted that what is a minority language in one country may well be the dominant language in another. Thus various dialects of German constitute a minority language in France, but Standard German is the official language of (among others) the Federal Republic of Germany. In such a situation the users of the minority language will have a standard to relate to, if they wish to avail themselves of it.

Politicized Language

A. Davies

This article is divided into three parts. In the first part, the classificatory surface of language and the issue of 'avoidance' are considered; in the second part, the correlation model in sociolinguistics and its call for 'consciousness raising' are looked at; in the third part, language as a manipulator is considered and the issue of 'deliberate change' in language is examined.

A primary distinction is assumed between the language of politics and the politics of language. By the language of politics is meant the terminology and rhetoric of political activities and of politicians acting in their professional capacity, which is comparable to the discourses of other occupations such as the law, medicine, and religion. A further distinction is made between the politics of language and political (or politicized) language. The politics of language concerns policies and decisions about official and standard languages, language planning, language academies, and educational language policies. Politicized language is neither the preserve of a profession nor the office of the state; it is a resource open to all, allowing (or inviting) one to consider and to use language for suasion and control (including lying and deceit). This article focuses on politicized language and touches only fleetingly on the politics of language, but there is inevitable overlap between the two concerns, if only because politics is necessarily concerned with control, with advertising, with propaganda, and with ideology. It is in this overlap that politicized language and the politics of language meet.

Underpinning the approach taken in this article is a longstanding opposition in philosophy. The epistemological concept of realism assumes that universals exist, implying that scientific truth is attainable and unitary. The opposing doctrine of nominalism makes no such assumption, claiming rather that what is known is always relative, relative to space and to time. Householder (1952) has teasingly suggested that when transferred to linguistics realism may be regarded as the 'God's truth' approach, while nominalism is the 'hocus-pocus' approach. A nominalist position can be argued on the grounds that a realist view denies a critical capacity of flexibility to the language user, imprisoning him/her within the castle of his/her own language. Such an extreme Whorfian position (Whorf 1940) can be challenged on the grounds that it makes no allowance for a separation between language and thought.

1. Language Classification

The concern with the politicizing of language through its classificatory systems emerges more in the discussions of sociologists than of linguists. Edelman (1977) points to the way in which differing connotations for the word 'poverty' may lead to quite contradictory philosophies and political actions (the poor as fraudulent and lazy; the poor as victims of exploitation). Edelman refers also to the social creation of social problems through the conventional mode to naming and classifying. Terms like 'mental illness,' 'criminal,' and 'drug abuse' focus attention on the alleged weakness and pathology of the individual, while diverting attention from their pathological, social and economic environments. 'Conventional names for social problems evoke... dubious beliefs and perceptions. The "welfare" label connotes to many that the problem lies in a public dole, which encourages laziness' (Edelman 1977: 27). Arguments of this sort relate back to the views of earlier sociologists such as C. Wright Mills: 'The languages of situations as given must be considered a valuable portion of the data to be interpreted and related to their condition' (Mills 1940: 911).

Strong (1984) reminds us of Nietzsche's argument about idols which arise out of the anarchy fundamental to human creativity. In the case of language, Nietzsche maintained, 'we suffer from the malady of words and have no trust in any feeling not stamped with its special word' (Strong 1984: 101). According to this view, language, the classificatory tool, comes to dominate the way one sees the world.

In his discussion of sexism, Bolinger (1980), commenting on the words used for women, remarks that 'As with other relatively powerless classes, there is a heavy representation of epithets and similar unfavorable terms, more than for men' (1980: 91). Outside the language and gender issue, similar critiques are made of the ways in which vocabulary can be used to denigrate minorities generally, leading perhaps to the logical dilemma pointed out by D'Souza (1991): 'At Michigan, architecture professor James Chaffers delivered a lecture in which he called the term minority "insulting... minority is the late twentieth-century term for nigger." This fact surely would come as news to most students and faculty at Michigan. No one seems able to keep track of the changing vocabulary, and a white student who used the term "minority" would hardly be giving proof of racist sentiment, conscious or otherwise' (1991: 156). What is underlined here is the dilemma of ever being completely 'politically correct,' that elusive and probably fugitive attempt by 'right-wing writers to isolate and demonise a growing movement among radical students and teachers, minority rights advocates, literary theorists, environmentalists, and others who were concerned to eradicate various forms of prejudice' (McArthur 1992). The Oxford Modern English Dictionary (1992) defines political correctness as '(esp. in the US) avoidance of forms of expression and action that exclude or marginalize racial and cultural minorities; explicit multiculturalism.' The merest suspicion of racism and sexism in words is therefore the cutting edge of politically correct movements. D'Souza quotes Alexander Aleinikoff, a Michigan law professor, on the need for avoidance in the protection of minorities: 'There is some speech that contributes nothing to the dialogue. To me, racial epithets are not speech. They are bullets. They can be outlawed in the same way that bank robbery can be outlawed' (1991: 152). Aleinikoff's confidence is surely excessive. It may be possible to outlaw such epithets, but such action does not remove the problem, which in essence has nothing to do with epithets, however bullet-like they may be. The problem remains, and replacement epithets become in their turn replacement bullets; or they may be replaced by an uncomfortable silence, which, however racially charged, cannot be outlawed anywhere.

Such views on classification (similar to those in the language and gender area with regard to the non-inclusive pronominal and reference systems: *man* for both male and female; *he* for he and she) misinterpret the nature of language and exaggerate the importance of language. If language variety is accepted as basic to the nature of language, then derogatory and negative language cannot be removed by fiat any more than swearing and vulgarity can. There is something naive about the claim that by acting upon the language society and social attitudes are thereby being changed. If only it were that easy! True, there is the argument for consciousness raising.

2. Consciousness Raising

A main motivation for movements such as the inclusive language movement (Doody 1990) is to bring about change in language use. Such movements or campaigns are said to be concerned with 'verbal hygiene.' Cameron (1990) brackets the campaign against sexism in language with the Plain English and Artificial Language movements as well as with language standardization activity. Although in her view these are all examples of metalinguistic activity, clearly they are all intended to affect language use. And where they do not, the aim is that they should raise the level of public consciousness about what language means or can be interpreted as meaning, thereby helping forward a change in attitudes towards minorities.

But there is another area in which consciousness raising has been important in language considerations. This concerns those practices in sociolinguistics reflecting the proposition that 'language reflects society.' Cameron takes proponents of such a proposition to task, directing her major criticism

against the work of Labov and his followers working in the 'variationist' or 'quantitative' paradigm. Such an approach, Cameron insists, based on a correlational methodology, matching patterns of linguistic variation with social or demographic features, is inadequate.

> Two things about this kind of account are particularly problematic. The first problem is its dependence on a naive and simplistic social theory. Concepts like 'norm,' 'identity' and so on, and sociological models of structures/divisions like class, ethnicity and gender, are used as a 'bottom line' though they stand in need of explication themselves. Second there is the problem of how to *relate* the social to the linguistic (however we conceive the social). The 'language reflects society' account implies that social structures somehow exist before language, which simply 'reflects' or 'expresses' the more fundamental categories of the social. Arguably however we need a far more complex model that treats language as *part of* the social, interacting with other models of behavior and just as important as any of them.
> (Cameron 1990: 81–2)

Concentration on the classificatory role of language, particularly with lexical labeling, allows the politicizing of language change, often of a quite simplistic kind. Indeed, those active in studies of language and gender have now turned away from such concerns to a more considered interest in uses of gendered discourse. A similar turning-away was observed a generation ago with the rejection of the early Bernstein (1965) contrast of the surface features of restricted and elaborated codes in favor of a discourse/genre model.

Linguistic or sociolinguistic attention on the reflection of society in language, validated in terms of the Labov variationist or quantitative model and using a crudely correlational methodology, appears to have as its concern the description of language in social terms. It is important to note that in spite of her objection to the underlying assumption of such an approach, Cameron does not reject the intention. She regards the Labov paradigm as inadequate rather than false or wrong-headed. Such an account offers further description of language and probably a wider understanding of social categories. Indeed, despite Labov's desire to bring society into linguistics it is probable that his efforts have succeeded in incorporating some aspects of language within the social domain. As a result, whatever consciousness raising is brought about by quantitative approaches, it is likely that those who benefit most are students of sociology rather than of linguistics; they are even less likely to be members of the general public. It is noticeable that while Cameron's objection is on the grounds that the quantitative approach is basically politicized (taking for granted such questionable concepts as norm and identity) she herself does not escape from the need to politicize, in as much as she

sees language as purely social to the exclusion of the individual.

3. Deliberate Change

Language as a manipulator and the issue of (deliberate) change in language are examined here. The genre debate in education is considered as liberating or confining discussion and learning. Finally, the issue of free speech is raised.

Fairclough (1989) addresses the issue of control directly. For him 'language has become perhaps the primary medium of social control and power' (1989: 3). In order to bring about political and social change—and Fairclough is quite open about his own political views and about his desire for such change—he recommends once more a form of consciousness raising, through what he and his colleagues term 'critical language study.' This technique 'analyses social interactions in a way which focuses upon their linguistic elements, and which sets out to show up their generally hidden determinants in the system of social relationships, as well as hidden effects they may have upon that system' (1989: 5). Fairclough's examples of ways in which the powerful manipulate language to their own ends draw on their control over discourse types and orders of discourse. He cites the examples of job interviews and of medical examinations, and claims that where such encounters are crosscultural 'white middle-class gatekeepers are likely to constrain the discourse types which can be drawn upon to those of the dominant cultural grouping' (1989: 47). Fairclough appears to assume a fairly strong deterministic position about the use of politicized language. Ikle (1973), on the other hand, while equally clear as to the manipulation of language for political ends (in terms of, for example, bargaining, negotiating, propaganda), assumes that the manipulator actively manipulates: 'as seen by the opponents in a bargaining situation, communication ordinarily serves to convey some truthful information as well as to give false information (or at least to conceal the truth)' (1973: 837). Economizing with the truth is obviously not the preserve of an ambassador, defined by Sir Henry Wotton (1568–1639) as 'an honest man sent to lie abroad for the good of his country.'

Controlling genres or 'discourse types' (Fairclough's preferred term) offers a more solid view of language manipulation. Wallace maintains that 'one of the goals of critical reading is the reconstruction of the discourses within the text. This means looking at the "obvious" and the "taken for granted" in critical ways' (see *Ethnomethodology*) 'so that, for instance, ways of talking about women, blacks, and foreigners, which are so commonplace as to be seen as obvious by most readers, are placed under scrutiny' (Wallace 1992: 68). However, the attempts by genre theorists (Kress and Hodge 1979) to promote the teaching of

genre as the major activity in the language classroom may be equally manipulative in that the pedagogy may allow for no alternative ways of constructing genres. Such a pedagogy stems from a deterministic and enclosed view of language. In all concerns with politicization it does seem important to retain a sense of alternative ways of behaving, of alternative language encodings. An issue which resonates through the entire field of politicization is that of free speech. Its consideration is at the heart of the detailed exposure of political correctness (PC) by D'Souza (1991), and one's decision on what position to take up on free speech—as with obscenity and censorship—may reflect a deeper philosophical choice between realism and nominalism.

Fairclough maintains that free speech is a myth because of general social constraints of appropriateness: his view is the genre one that in discourse types there are firm conventions about who has rights and who has access. Harris (1990), however, appears to take up the extreme absolutist position that free speech is an inalienable right: 'freedom of speech is basically the right to participate in those communicational activities available in virtue of one's membership of a linguistic community' (1990: 159). In some measure, as D'Souza's discussion makes clear, these two views are not really in conflict because they are concerned with different aspects. Harris would accept that, in terms of acceptability, some things are not said (in church, in public, in formal settings, etc.); while the freedom he supports is to express one's views, beliefs, and so on. Of course, the freedom even to break the conventions of what is said and not said may not be appropriate, but nevertheless it should not be prevented.

Fairclough's 'myth' is only a myth if his deterministic view is accepted; what Harris shows is that in spite of conventions and constraints people do have freedom of alternative speech. Language does not reflect society, as Cameron argues; language is properly independent of society and while it may be politicized it does not have to be.

Informing the discussion, not always benignly, has been B. L. Whorf and the linguistic relativity hypothesis associated with him and his teacher Edward Sapir. The extreme Whorfian position (which has been aligned with realism) can be challenged on the grounds that it makes no allowance for a separation between language and thought. It has been argued that language and thought, while obviously connected, are distinct. While thought does make use of language as a medium of expression and also as a vehicle for its own activity, it can operate without the use of language and it can also act creatively and plastically on the language with which it is garbed.

Interestingly, it is to a creative writer that one can turn for an understanding of the subtle relationship between language and thought. George Orwell in his essays and novels recognized the nature of politicized language: 'In our time, political speech and writing are largely the defence of the indefensible.... Thus political language has to consist largely of euphemism, question-begging and sheer cloudy vagueness.' At the same time, what the code 'Newspeak' (in his novel *1984*) shows is that his animus was directed against invented and artificial languages such as Basic English. Control may be exercised through such devices, but the individual remains the arbiter of his/her own natural language. After all, in *1984* it is thinking not language which is the object of control.

Politics and Language

P. A. Chilton

When politicians are challenged over their use of 'language,' they often reply that the questioner is merely 'playing with semantics,' or confusing 'style' and 'content.' Nonetheless, politicians rely on using language in order to communicate with their electorates or subjects: they make speeches, employ public relations experts, and write in newspapers. Political life, whether totalitarian or democratic, depends in varying degrees on physical sanctions and coercions. However, whether democratic or totalitarian, regimes must communicate in order to inform, issue commands, legislate, persuade, and so forth. This article outlines some of the ways in which 'language' and politics are related.

1. Language, Discourse, and Power

In order to study the relationship between language and politics, it is necessary to make certain termino-logical distinctions and assumptions. The term 'language' itself appears to have various meanings in the everyday contexts in which it is associated with politics. For instance, when one speaks of 'the language of politics' one seems to imply that it is different in some way from other linguistic behavior; when one speaks of politicians 'misusing or abusing language,' the assumption is made that language is normally and naturally innocent. Other instances—for example, 'the English language'—seem to be entirely apolitical. Yet is this really so?

It is useful to distinguish 'language,' in the sense of the universal capacity of humans in all societies to acquire and to use language, from two other concepts: 'a language' (see *Language*) and 'discourse' (see *Discourse*).

As for the term 'politics' itself, from the point of view of linguistic study, there have been two guiding assumptions. First, one might adopt the classical definition of politics as the art of governance. This leads either to the linguist attempting to describe objectively the properties of the uses of language in various situations and institutions conventionally recognized as political; or to the linguist, rhetorician, or professional communication specialist providing technical advice and training to those who govern. Second, politics can be thought of as being about power, conflict, and cooperation. This leads to the view that politics is not confined to governments, parties, elections, and so forth, but pervades inter-personal interaction in everyday life, a view which has produced studies whose purpose is not merely to describe, but also to expose and criticize the relation-ship between language and the wielding of power.

Although there is no clear dividing line between descriptive and critical approaches (since critical approaches themselves necessarily depend on de-scription), it is convenient nonetheless to make the distinction. Consequently, Sect. 2 considers the first of these two perspectives, the predominantly descrip-tive perspective. Sect. 3 considers the second per-spective, critical linguistics or discourse analysis.

2. Descriptive Approaches

For many centuries in the West the study of the practical use of language in public life was moulded by the canons of Classical rhetoric. Political life and rhetorical theory are interconnected. The theory and practice of public oratory in legal and political situations appears to predate the first codifications of rhetorical techniques. According to Cicero, rhetoric was first codified in the Greek community of fifth-century Sicily, in order to promote legal proceedings against recently expelled tyrants. These methods are said to have been subsequently intro-duced to the Greeks in 427 BCE by the Sicilian envoy to Athens, Gorgias, who was himself a famous rhetor.

Over the following centuries codification devel-oped alongside a philosophical debate which centered on the question of whether the rhetor's role was a purely technical one, without moral responsibility for

the ideas expressed, or whether the very distinction assumed in this question—that is, the distinction between ideas and expression—was invalid. In the latter case, since ideas and expression could not be separated, the rhetorician and the orator had to bear moral responsibility for their words. For some thinkers—for example, Socrates as represented in Plato's dialogues—the art of persuasive speaking was necessarily deceptive. For others—for example, Isocrates (436–338 BCE) and Cicero (106–43 BCE)—the inseparability of words and ideas demanded a moral commitment on the part of speakers.

2.1 Rhetorical Description

Rhetoric manuals were developed throughout the Classical Greek, Roman, and Medieval periods in the form of highly structured lists, purporting both to describe and prescribe effective techniques for influencing an audience's thoughts and emotions. This is true of the best known and most influential Classical rhetoric manuals—Aristotle's *Art of Rhetoric*, Cicero's *On the Public Speaker*, Quintilian's *Training for Public Speakers*, and the anonymous *Rhetoric for Gaius Herennius*.

All the applications of rhetorical theory and practice were conceived as part of the political life of the community. Three principal applications were recognized: judicial rhetoric for presenting cases in the courts, 'deliberative' rhetoric for promoting policy in political assemblies, and 'demonstrative' rhetoric for ritual use on state occasions. Broadly speaking, the manuals offered speakers the following five-part methodology, adaptable to each of these types of public occasion.

(a) Psychological techniques of memorizing speeches were elaborately devised. It was recognized that maximum effect on the audience could be achieved if a speech were made to seem unpremeditated. The modern equivalent is the politician's use of the 'auto-cue'—a transparent screen, invisible to the audience, onto which is projected the text of the speech.

(b) Under the rubric 'Delivery,' techniques of voice control, gesture, and facial expression (see *Kinesics*) were described and recommended for different persuasive purposes. Twentieth-century politicians have in some significant cases been trained by actors. United States ex-president Ronald Reagan actually was a former actor.

(c) What was termed 'Invention' were in effect recommendations for finding arguments, proofs, and convincing turns of phrase. The latter might be quasi-logical proofs or plausible aphorisms.

(d) Devices of this kind had, of course, to be sequentially presented during the course of a speech, and the 'Disposition' or arrangement part of the manuals specified types of section (like the 'exordium' or rousing introduction, the statement of facts, the proofs themselves, and the 'peroration' or summing up), and ways of ordering them.

(e) The 'Style' section produced an elaborate and lengthy repertory of verbal ornaments. Under the subheadings 'figures of thought' and 'figures of speech' politicians and other public orators were introduced to a range of verbal techniques. Examples of these included questions—'rhetorical questions' (supposedly having an obvious answer), self-answered questions, strings of questions, and the exasperated question addressed to an individual. Furthermore, recommendations were made for verbal arrangements within and between sentences. Examples would be: repetitions of words ('How, how can they do it?'); antithesis ('We propose to raise living standards, the party opposite to degrade them'); sentence pairs of equal length; and alliterative effects. A third technique, felt to be particularly powerful, was the use of metaphor and related devices of analogy and resemblance, such as allegory, irony, and even onomatopoeia.

These techniques were recognized and practiced well into the early modern period. They were undoubtedly of importance to orators in the major Western political developments of the seventeenth to the nineteenth centuries. In the latter half of the twentieth century, the growing importance of all forms of electronic media in the life of almost all political systems also brought with it increased importance of the techniques of verbal presentation. Although Classical rhetorics had long since dropped out of even elite education, many of the techniques apparently continued to be employed. The reasons for this could be transmission in Western verbal culture; alternatively, rhetorical skills could be universal skills spontaneously produced by experienced speakers.

2.2 Modern Descriptive Approaches

Modern linguistics has made available methods of analysis and observation which have been applied to the verbal behavior of politicians.

2.2.1 Redescribing Rhetorical Devices

In line with the Socratic strand in the rhetorical tradition, some analysts have focused on the persuasive, deceptive, and manipulative aspects of politicians' language (see *Manipulation*). Modern linguistic categories of analysis are used to catalogue 'devices' or 'strategies.' The traditional rhetorical way of classifying is thus recast in terms of phonological, syntactic, lexical, semantic, pragmatic, and textual levels of description.

For example, on the phonological level can be placed devices of alliteration, assonance, and rhythm (e.g., 'I like Ike' as a slogan in the Eisenhower election campaign). On the syntactic level, one might list the use of agentless passives: e.g., 'Decisions were taken' fails to mention the identity of the decision-maker. On the lexical level, descriptive approaches will note 'jargon' words, that is words characteristic of some closed group of speakers, neologisms, acronyms, and word formation ('quangos' for 'quasi-autonomous nongovernmental organizations'). On the semantic level, there has been interest in semantic restriction and shifts arising from, for example, paraphrasing and euphemism. On the textual and pragmatic level, linguist commentators have noted modes of argumentation: for example, the use of quoted authorities.

2.2.2 Verbal Behavior of Politicians

Some descriptive analyses do not concern themselves with the problem of rhetorical deception, but seek to provide empirically valid, evaluation-free accounts of politicians' verbal behavior. The descriptive categories used here are the linguistic ones just referred to. In such studies, the analyst is concerned with the verbal characteristics of politicians speaking in speech settings such as parliaments or other assemblies in parliamentary democracies. Here too the customary levels of linguistic description provide a framework.

For example, it has been found that in the Austrian parliament politicians systematically switch between dialect and standard forms (see Moosmüller 1989). Dialect forms and standard forms of a language are subject to socio-political evaluation in all national states: they may be variously associated with sociability, aggressiveness, lack of intelligence, trustworthiness, etc. Politicians who rely on votes tend to exploit dialect switching. In the Austrian parliament, if dialect variants are used, this is only in part because of the social origin of the speaker. Moosmüller (1989) argues that the use of dialect switches also interacts with pragmatic structure in the following way. Although speeches themselves are usually prepared, transitional introductions and interruptions have to be managed more or less spontaneously, and it is at these junctures that dialect switches are used. The reason for their use appears to have less to do with the relatively spontaneous, and therefore less controlled, mode of speaking, than with the social evaluation of dialect forms. Because the dialect forms are negatively evaluated, they can be used to treat interventions and so forth as not-serious and to devalue opposition. Interestingly, this does not occur when speakers (either male or female) are responding to women parliamentarians, presumably because of gender-based expectations of politeness.

Some empirical studies go further than description, and, like the Classical oratory experts, seek to provide rhetorical prescriptions for professional politicians. Videorecording techniques have made it possible to analyze minutely both the verbal and the nonverbal components of the skilled oratorical performance. Gestures, voice quality, wording, phrasing, and speech structure can all be correlated with audience response in order to identify effective techniques.

One major study (Atkinson 1984) has used this methodology for identifying the techniques used by successful politicians to produce 'clap-traps'—those points during the delivery of a speech at which an audience receives a verbal or gestural signal from the speaker that applause is appropriate, or at which television production staff, by the same signal, switch camera focus. At these junctures it is possible to observe simultaneous cues that use gesture, intonation, specific verbal patterns, and pauses. Two important kinds of verbal pattern used in this way are the 'list of three,' and contrastive pairs (or antithesis). Here is an example of the former.

George Wallace, in his inaugural speech as governor of Alabama in 1963, elicited applause for his particular political message with the following list of three:

... and I say segregation *now*,	(1)
segregation *tomorrow*,	(2)
and segregation for *ever*.	(3)

The first two italicized words were accompanied by rising intonation and followed by brief pauses; the third italicized word was accompanied by falling intonation and was immediately followed by applause.

2.2.3 The Mind of Politicians

Whereas such studies concentrate on delivery and phrasing techniques, some analysts, particularly in the discipline of political science, have analyzed the 'content' of political speeches. The purpose of this type of analysis has been to discover the mental predispositions of individual political decision makers, or groups of decision makers. The data are usually the transcripts of political speeches, or translations of transcripts. In the latter case no account is usually taken of cross-language differences.

The content analyst will be interested in the relative frequency of occurrence of particular vocabulary items, such as 'peace,' 'freedom,' 'democracy.' Linguistic 'indicators' of particular political proclivities may be looked for, such as words indicating hostility, aggressiveness, or cooperativeness. In many studies of this type the texts are 'coded,' i.e., the linguistic expressions at issue are tagged in some way by a team of readers. Variants of 'content analysis' are 'operational coding' and 'cognitive mapping.' The term 'operational code' arose in the study of

Bolshevist ideology: the policymakers of the Stalinist period were assumed to behave according to a certain belief system and a certain set of practical policy rules, in short, according to an 'operational code.' In this method, documents and speeches were analyzed by a team of analysts in order to reconstruct this code, in the belief that the future actions of those using it could be predicted. The term 'cognitive map' refers to a technique of analyzing documents and speeches in which the aim is to specify, in the form of a mathematically describable graph or 'map,' the network of causal links that individual policymakers claim or assume between events, actions, and entities in the national or international domain. However, none of these methods of analysis rests on a detailed linguistic theory or linguistic description.

2.2.4 Ideology

The study of the linguistic or textual characteristics of ideologies has had numerous practitioners. In addition to the study of Soviet Communist ideology, which was a concern for some American analysts during the Cold War period, European analysts, in the aftermath of the Second World War, produced studies of fascist ideology. Marxist scholars, however, had for a long time used the notion of ideology in relation to capitalist society, proceeding on the hypothesis that ideology and language were interrelated (cf. Althusser 1971). Many approaches have been applied, but the following aspects of languages and their use in social and political life are relevant (see *Ideology*).

The means of controlling the languages used, the media of public information, and the content of public media are under *direct* political control in totalitarian states. Propaganda and censorship depend on control of the press, radio, and television. Less well-known is control through language planning, in particular the planning of language teaching curricula in schools. In Mussolini's Italy, for example, the teaching of Italian through an increased emphasis on Latin grammar was introduced, the teaching of German was given priority, and Arabic was promoted (for communication and control in the African colonies).

The effect of National Socialist ideology on the language system itself is most obvious on the lexical level. On the lexical level the changes in vocabulary, both in terms of its structure and in terms of denotative and connotative meaning, which came about as a result of national socialism in Germany and as a result of the fascist party in Italy have become widely known. In German, for example, words like *Volk* ('folk' or 'people') and its derived adjective *völkisch* became conventionally associated with National Socialist beliefs concerning race, and after 1945 became unusable in German political discourse. Other well-known terms are *Führer,*

Anschluss ('joining on' the term used for Hitler's annexation of Austria), *Selbstgleichschaltung* ('voluntary falling into line').

At the level of the use of language in particular situations, descriptions of totalitarian language use have successfully examined characteristic narrative. It is within the narratives—the histories, accounts, stories, explanations—circulated through the controlled media, including education, in a totalitarian society that the individual lexical items mentioned above acquired and retained new conventional meanings.

One of the main problems in approaching language and politics by means of the concept of ideology is the fact that the latter term is often taken to imply a distinction between a false representation of reality and an objectively true one. Yet there is no guarantee that the analyst of ideology occupies a completely neutral position.

3. Critical Approaches

The descriptive strand of study that has been so far discussed tends to take an epistemological position that is close to positivism. That is to say, it tends to treat the political language phenomena it is submitting to scrutiny as neutral independent facts, and to treat the observing analyst as a neutral independent scientist. Questions of value, and questions of the analyst's own standpoint, tend to be excluded or occluded. This is not to say that questions of value do not arise from time to time—as in the Classical tradition in rhetoric. Nor is it to say that a precise description of political language phenomena is not essential for what is described below as the 'critical' strand in the analysis of politics and language.

This approach is distinctive because it assumes a different conception of politics—a conception which emphasizes the importance of power from the point of view of the subject citizen, and assumes connections between the 'macro' structures of state institutions and the 'micro' structures of everyday, person-to-person relationships and interactions. This approach is more characteristic of European than of North American scholarship, although some impact on American social science became visible from the early 1980s (e.g., Shapiro 1984).

Among the European social theorists who have been influential, in different and—some scholars would argue—opposed ways, are Jürgen Habermas and Michel Foucault. Habermas is associated with Frankfurt School 'critical theory' and views the analysis of social practices, including linguistic ones, as a rational enterprise whose purpose is emancipation. 'Distorted communication' derives, in the Habermasian view, from unequal access to the communication process, which itself is a function of the exercise of power. Foucault is associated with a

concept of discourse which is examined more closely below (see *Discourse*).

Because of the ambiguities of the term 'language' discussed in Sect. 1, many writers have come to prefer the term 'discourse.' Linguists (as also philosophers, psychologists, information scientists) use the term to refer to language-in-use, as distinct from the language system conceived as grammatical rules, patterns, or properties. In studying discourse they focus on written text, on spoken utterance, and on the processes whereby individuals process texts and utterances (see *Speech and Writing*).

In the 1970s and 1980s, on the other hand, social scientists (including political scientists), were influenced by the way the term 'discourse' was used in European literary and social criticism by writers such as the French philosopher Michel Foucault. Such studies are sometimes referred to as 'postmodernist' or 'deconstructionist.' Some linguists concerned with the critical analysis of language use in relation to politics have also adopted these ideas (e.g., Fairclough 1989).

Among the prominent notions emphasized in this line of thinking are the following.

(a) The relationship between language and power (see *Power and Language*): control and dominance, it is claimed, are exercised increasingly in the modern period by linguistic means.

(b) The pervasiveness of power: control and dominance are everyday phenomena found in encounters of many kinds, e.g., in the classroom, in doctor–patient relations, in the relations between men and women.

(c) The relationship between linguistic and nonlinguistic practices: while the use of language is increasingly crucial in political life, other nonlinguistic forms of action are associated with language, e.g., architectural arrangements.

(d) Orders of discourse: types of talking and writing (e.g., interview, conversation, letters) play different parts in different institutions of a society (e.g., in education, policing, journalism, commerce). In addition, an entire society or polity can be thought of as constituted from several interconnected 'orders of discourse' (e.g., education, political institutions, religion, law, medicine, and so forth), and this overall structuring of a social and political entity, viewed from the point of view of discourse, has also been termed 'an order of discourse.'

3.1 National Language

It can be argued that the concept of 'a language' is itself a political concept. A language, it has been said, is a dialect with an army and a navy. The point of the joke is that what is commonly called 'a language' is not a homogeneous system, but a collection of dialects and varieties. These dialects and varieties may be distinguished in terms of their geographical distribution, but also in terms of their social distribution (see *Language*; *Dialect and Dialectology*). In addition, individuals will command, in different degrees, depending on their socioeconomic provenance and/or their skill, a variety of linguistic resources relating to different functions, situations, and institutions in the culture.

At the level of both intrastate and interstate politics, dialect is significant in the following sense. Dialect boundaries are naturally fuzzy: they do not coincide with political boundaries (see *National Language/Official Language*). However, nation-states have usually selected, codified, and elaborated the dialect of a politically dominant group as the standard. The term 'dialect' includes phonological, lexical, and syntactic variations.

For example, modern standard British English derives from the East Midlands dialect spoken by the merchant class at the end of the medieval period. This dialect subsequently extended the range of functions and situations in which it was employed as growing numbers of people adopted it, and the dialect was increasingly spoken or written in institutions of political power, such as government, administration, law, and religion. In the course of the political centralization of the UK this dialect ousted, for an increasingly wide range of functions, not only Latin and French, but also the Celtic languages, as well as other dialects of English.

In colonial settings, the use of the colonial power's national language (English, Spanish, French, Russian, for example) at the expense of local languages has the most obvious political significance (see *Linguistic Imperialism*). Even in the postcolonial period, states seeking global influence institutionalize overseas language training: the USA and the UK invest to varying degrees in language export, and France likewise seeks to maintain 'la francophonie.' Domestically, governments have more or less explicit policies with regard to standard and majority languages. In many instances the selected standard has been imposed by law and not infrequently enforced by physical sanctions (see *Linguicide*).

It is in this sense that the successful elites of emergent nation-states have typically selected a dialect and developed and imposed a national language. The political effect is both international and domestic. On the one hand, the 'national language' externally defines and differentiates nation-states in the international system; on the other hand, the 'national language' internally defines and differentiates, to the extent that this standard is not equally distributed throughout a population at a given period of time, elites and non-elites, the powerful and the less powerful. It follows that the concept 'a language' has an inherently political basis.

3.2 Critical Discourse Analysis

The term 'critical linguistics,' originally indicated techniques of descriptive linguistics to expose uses of language which were claimed to manipulate addressees, deceive them, or hide material from them. The early emphasis on lexis and syntax had the disadvantage of giving the impression that manipulative, deceptive, or dissimulating procedures, and hence ideology, were attributable to the language system *as such*, and that they had a deterministic quality. Later work has emphasized the receiver's end of the communicative process, however. Feminist linguists and discourse analysts in particular have clarified the importance of this subjective dimension (see *Ideology*; *Manipulation*; *Discourse*).

The linguistic discipline of pragmatics has drawn attention to the fact that language-in-use is a form of social action (see *Pragmatics and Sociolinguistics*). The predominant Anglo-American approach, however, emphasizes individual action and has neglected the dependency between individual acts, including speech acts, and power (see *Speech Act Theory: An Overview*; *Power and Language*). A speech act is an utterance which is identical to some social act, which may be an institutionalized one. For example, promising, requesting, warning, are generalized speech acts, and baptizing, sentencing, declaring war are highly institutionalized ones. Both, however, can be seen as dependent on structures of power.

In the latter examples this is self-evident: only certain appointed individuals, operating according to established procedure, can issue such speech acts. Not everyone can declare a war or sentence someone to prison. The former examples also depend on power. Speech acts have been said to depend on 'felicity conditions.' That is to say, they do not work unless certain conditions obtain: for example, a request only makes sense if, among other things, the speaker wants the hearer to perform some action, and believes the hearer is capable of performing this action. This formulation, however, omits the fact that in certain situations only speakers occupying a certain status with respect to the hearer are entitled to issue a request. Thus many of such examples clearly depend on the *legitimacy* of the speaker and the act. In other words, they depend on a characteristically political concept.

Another aspect of issuing speech acts is what have been termed 'politeness phenomena' (see *Politeness*). Among the generalized or noninstitutionalized speech acts many can be issued in various ways, depending upon circumstances. A request can be made directly or indirectly, with or without overt politeness words: for example, 'Move along there, please,' 'Get out of the way,' 'It's a little crowded in here.' Indirect politeness formulas avoid direct verbal reference to the speaker, hearer, object, or event. In addition, politeness may be achieved by creating common ground between the speaker and the hearer, for instance, by saying 'we,' mentioning common experiences, or using phrases common to the interlocutors.

In most accounts in the literature of pragmatics such phenomena are treated as individual strategies. However, such strategies are clearly useful in the political context. Indeed, the avoidance strategy can be used, precisely because it is conventionalized in politeness practices, to misrepresent, underinform, and evade responsibility. The common ground strategy likewise is a natural procedure for political speakers seeking to establish legitimacy, credibility, and popularity. There is not of course any direct and necessary correspondence between such procedures and a particular type of political action. A critical analysis arises from the critical position of the analyst.

Conversation analysis (CA) has been successful in identifying and describing the sophisticated resources of speakers in the management of talk in various kinds of settings. The taking of turns, for example, is handled according to regular principles, with ends and beginnings of turns being signaled in subtle linguistic ways (see *Conversation Analysis*). The disadvantage of this approach is that it neglects the connection between the 'micro' setting and 'macro' institutions, including the distribution of power (see *Power and Language*). For example, building upon the techniques of CA, analysts have noted the skewed distribution of power in male–female encounters in certain social settings, which is reflected in turn-taking rights, interruption rights, and in speaking time allotted. In general, a high-status interlocutor may interrupt more readily than a low-status interlocutor, and in such instances the motive may be to exercise control.

Conversation analysis can be extended in another politically relevant sense, if the micro-analyses of conversation turn-taking are seen as a metaphor for the macro-communicative processes of the polity as a whole. Such a metaphor points not merely to political questions of censorship, freedom of information, and access to public media, but also to the fundamental question of freedom of speech—in short, to how 'turns' are allocated to individuals and groups in the global 'conversation' of public communication. Placing conversation analysis in the context of political discourse analysis necessarily takes this question beyond simple legal entitlement, and leads to investigation of non-obvious restrictions on access to media and on rights to adopt particular communicative roles.

Some of these implications have been given formulation by using the notion of 'subject position.' The term 'subject' in this notion is deliberately understood in two senses: the political sense in which a person is a passive 'subject' in a political

jurisdiction, and the quasi-grammatical sense in which a 'subject' is (at least in many sentences) the active 'doer.' On this basis the critical discourse analyst proceeds to show how a 'subject' is both determined by the discourses available, but is also thereby constituted as a social actor. This is not a determinist model, for 'subjects' have scope for creative maneuver as well as for stereotypical behavior.

An example of this type of analysis would be the discourse of a social institution such as a school or college. Such institutions are structured in terms of the discourse types that are viewed as legitimate for the various functions of the institution: lectures, teacher–pupil talk, staff meetings, examinations, for example. Within each discourse type, certain 'subject positions' are quite rigidly prescribed, in terms of what each can say and when, for the roles of teacher, lecturer, pupil, examiner, chairperson, and so forth. From the point of view of critical discourse analysis such distinctions are not merely a matter of organizational efficiency, but a means of maintaining and reproducing social control, and are thus a part of a political analysis.

A second example would be the analysis of the discourse of political parties. All political parties need to have the support of electors. These electors therefore need to be addressed (media broadcasts and the like) as if they were all members of a homogeneous entity. This may not of course be the case, where a political party needs support from electors of diverse social origins. Another way of stating this problem for the political party is to say that it needs, in its public discourse, to construct a 'subject position' that can be 'occupied' by diverse hearers.

The linguistic means for such constructions can be detailed through analysis of texts and transcripts, and they are of course highly variable and dependent on the analyst's own viewpoint. However, in particular instances, syntactic and other features can be indicated as involved in the projection of subject positions. In the following extract from a radio interview (December 17, 1985) with the then UK Prime Minister, Margaret Thatcher, the use of lists with syntactic coordination can be related to the need to specify a notion of 'the people' which will be assented to by different social sectors:

> and I was always brought up with the idea 'Look, Britain is a country whose people think for themselves, act for themselves, can act on their own initiative, they don't have to be told, don't like to be pushed around, are self-reliant and then over and above that they're always responsible for their families.'

As Fairclough has argued, the syntax of coordination appears here to serve the function of listing attributes with the implication that they are connected in a composite whole. It would also be relevant, in the critical discourse perspective, to note that the speaker assumes the authority to speak truthfully to the people about themselves, and that she does so by reproducing stereotypes that constitute common ground. The speaker thus assumes a particular subject position, a position aided by privileged access to an authoritative medium, and verbalizes a subject position for hearers of the interview.

There are two closely interrelated ways of looking at meaning in relation to political discourse. First, words can be considered in so far as they are part of a resource potentially available to anyone who can be said to know a particular language. Second, meaning can be considered in relation to the words and sentences of a text or utterance produced in particular discourse types.

Of the many theories of semantics, those approaches that have proved fruitful in the analysis of political discourse are those developed in cognitive science and in cognitive theories of comprehension. Texts and utterances are produced and comprehended at least in part by accessing mental representations of objects and processes. These representations include 'image schemata' (basic experiences like moving from one location to another), 'frame' (recurrent static objects like houses), and 'scripts' (repeated events like election procedures). Discourse types are partly characterized by their frames and scripts. They enable people to define what is 'real,' recognize situations, objects, and events, and to draw relevant inferences from allusions to them. Moreover, they provide the source for metaphor, where metaphor is understood as a major cognitive process not merely in persuasive rhetoric, but in conceptualization of complex or remote phenomena such as politics and international relations.

The politically important notion of racial, gender, and enemy 'stereotypes' can be understood in cognitive terms. The stereotype of the Jew, the German, the Communist, for instance, is a set of relatively stable mental representations linking attributes as well as attributed motives and goals. These attributes are negatively valued, and are repeatedly accessed in comprehension and perception. Stereotypes seem to arise when some, often peripheral, subset of a category is taken as the prototypical representative of the entire category. From a cognitive and a semantic point of view this process is metonymic—that is, the process whereby one thing is taken to stand for another thing with which it is associated. But the metonymy itself comes about as a result of some form of social or political promotion, usually by a socially and politically dominant group. The role of Western enemy image stereotypes was apparently recognized in Soviet foreign policy in the 1980s when efforts were made, often explicitly, to modify Western perceptions of the Soviet leadership.

590

The part played by metaphor in conceptualizing political realities is considerable. Metaphor is used by both theorists and practitioners, although in some political systems the distinction may be blurred. The most well-established metaphor for the state is the 'body politic.' In international relations theory, the state is often conceptualized as a person or as a container. Metaphors have implied meanings that can influence subsequent discourse in its conceptual aspect.

Thus, if a state is a body, it may also be sick, have a cancer within it, need a purge, and so forth. If it is a container-like entity, it will have internal and external affairs, and rigid separation of domestic and international politics might be a consistent part of the discourse's conceptualizations. Stalin's concept of politics and the state seems to have utilized a machine metaphor, entailing 'transmission belts,' 'levers of power,' etc.

Many other key political concepts show conceptual consistency of this type. The notion of 'policy' itself is often expressed in terms of movement along a path: a step-by-step approach, not deviating from the party line, dual track, etc. Crises are often seen as 'cross-roads' or 'turning points' of history. Such concepts might be linked to some larger system of political beliefs in which history is itself viewed as a path through time with an inevitable destination, or in which one's country has been sent on some 'mission.'

Particular metaphors may serve an important role in the conduct of political debate on problematic issues, both by providing a conceptual tool and by providing a means of referring to taboo topics indirectly. But in international, intercultural communication, including diplomacy, there can be distorting effects. An example, is the 'common European house' metaphor, used by the then Soviet president Gorbachev from around 1985, where the word 'house' translates the Russian 'dom.' The cognitive frame for 'dom,' however differs markedly from the stereotypical Anglo-American house, in so far as it typically represents a block containing separate apartments. The political implications of the metaphorical 'dom' and the metaphorical 'house' were divergent.

Although the systematicity and the productiveness of metaphors like these are clear, the implications are less so. It is possible that a well-established metaphor may in some discourse type tend to limit alternative conceptualizations. In persuasive political rhetoric, metaphors of this type may, because they appear natural, contribute to a speaker's legitimacy and credibility.

Power and Language

N. Fairclough

For the most part, questions of power have either been ignored in language studies, or dealt with at a rather superficial level. The richest insights into the relationship between language and power have come from increasing attention to language in social theory (its so-called 'linguistic turn'), in the work of Louis Althusser, Pierre Bourdieu (see *Bourdieu, Pierre*), Michel Foucault (see *Foucault, Michel*), Jurgen Habermas, and others. But in the 1980s and early 1990s, there have been attempts to operationalize these insights in language analysis, within 'critical linguistics,' and within more critical work in discourse analysis and pragmatics (see *Discourse; Pragmatics and Sociolinguistics*). A major problem for such work is that there are many divergent theories of power, which can lead to different approaches to language. There are also different levels at which the language–power relationship can be investigated: one could focus upon how power relations are enacted in discourse; or alternatively

upon power asymmetries associated with unequal access to certain languages or language varieties (including questions of language politics and language planning). This article concentrates mainly upon the former. It discusses, first, meanings of 'power.' It then moves from a rather static view of domination in discourse (see *Linguistic Imperialism*) to a more dynamic view of discourse as embedded within power struggles, discussing in turn power in discourse, power 'behind' discourse, and power struggle in and over discourse.

1. The Concept of 'Power'

Theories of power differ on fundamental issues; for example, whether power belongs to individuals or collectivities or systems, whether it necessarily involves conflict, whether it presupposes resistance, whether it is just repressive and negative (a matter of domination) or also enabling and positive. Within the bewildering divergences, it is possible to differentiate two major contrasting conceptions of power. The first and more general sense is power as transformative capacity, the capacity of agents to affect the course of events. Power in this sense may be enabling and positive as well as repressive, and it is a capacity possessed in some degree by any actor, dominant or dominated. Power in the second sense is a relational concept, 'power over,' and is linked to domination by individuals or collectivities. In critical language studies as in other spheres, there has tended to be a one-sided emphasis upon the latter, giving an overly pessimistic view of the sociolinguistic and discourse practices of a society (see *Language in Society: Overview*; *Discourse*) as simply an apparatus of domination. This article begins with domination and 'power over,' looking first in the section 'power in discourse' at the power of one participant over another in particular interactions, and then in the section 'power behind discourse' at the power of certain collectivities over others arising from their control over the sociolinguistic practices of a community. But in the section 'power struggle in and over discourse,' the more general sense of power is brought in, in the process of arguing that power in language is not simply domination.

2. Power in Discourse

Perhaps the most obvious instances of 'power over' and domination are cases where using language is a way of directly policing or mobilizing people. One example is the orders, threats, or diatribes parents sometimes use to control their children; a more institutionally regulated example is the discourse of military command (e.g., *Attention! From the left, quick march!*).

Domination takes a more indirect form in what are sometimes called 'unequal encounters'—types of discourse such as job interviews or medical consulta-

tions or lessons, where participants have unequal institutional status and authority. In such cases, higher-status participants (such as doctors or teachers) may control the development of the discourse, and the contributions of other participants to it, in various ways. For example, a medical consultation may consist largely of questions from the doctor, with the patient being limited to providing answers. This gives the doctor control over the content of the discourse (what topics are raised and how they are dealt with), as well as positioning the patient as a particular sort of medical subject (a passive participant in medical practice, a body worked upon by the doctor), in a particular sort of relationship (subordination and dependency) to the doctor. Generalizing from this example, one can say that power in discourse is exercised over content, relations between participants, and the identities of participants as social subjects.

Higher-status participants may also control the contributions of others by treating them as performances to be evaluated. In classroom discourse, for example, teachers systematically evaluate what learners say (e.g., Teacher: *What's the capital of France?* Pupil: *Paris, Miss.* Teacher: *Yes, Paris*). And there are various other ways of controlling contributions: by interrupting and curtailing them when they are judged to be irrelevant, by providing authoritative summaries or 'formulations' which impose particular interpretations upon them, by asking for them to be reformulated in different words which may force participants to be more explicit than they would wish to be, and so forth.

Power asymmetries between participants of different status may be evident in their orientation to what some pragmaticists call the 'face' of coparticipants (see *Politeness*). Participants may differ in how polite they are to each other, or in how directly or indirectly they say or write things which may be intrusive or offensive or threatening (compare, for example, two ways of asking a question which might be asked in a medical consultation: *How's your sex life?* versus *Are there any aspects of your personal life that might have a bearing on these problems?*). Participants may also differ in the extent to which they try to be accommodating to other participants, for example, by modifying their own usual linguistic practices toward those of others.

But it is not just differences in the institutional status of participants that give rise to discoursal inequality and domination; so too do differences in age, gender, cultural identity, and so forth. One aspect of unequal gender relations is that men sometimes dominate in female–male interactions. A study of the discourse of married couples in the USA, for example, (by Pamela Fishman, reported in Graddol and Swann 1989) showed that men gave women much less supportive feedback when they

were talking than vice versa, and that topics introduced by men were much more likely to be taken up than those introduced by women. Such inequalities are aggravated in institutional interactions, where the higher-status participants are men, or members of cultural majorities, and the lower-status participants are women, or members of cultural minorities (see *Minority Languages*). Some research has suggested that, in such situations, higher-status participants systematically misinterpret cultural differences in discourse practices (e.g., between the majority white community in the UK or the USA and black or Asian minority groups), as evidence of lack of cooperation, incompetence, etc., on the part of lower-status participants (Gumperz 1982).

So far 'face-to-face' discourse has been considered where participants are interacting at a particular time and place, and conjointly producing the discourse (though with different degrees of influence on it, as indicated above). But in the case of written discourse, and the discourse of the mass media (radio, television, film) (see *Media Language and Communication*), there is a separation between participants who produce the discourse and those who constitute its audience (be they readers, listeners, or viewers). Producers have power over audience in that they can determine what is included or excluded, and how people, objects, and events are represented. And since mass audiences are so potentially diverse, producers have to build into their discourse 'ideal' readers or listeners or viewers, which may significantly contribute to the social shaping of real readers, listeners, or viewers. Of course, audiences sometimes have means of counteracting the power of producers: they may stop reading or turn the television off, or be hostile audiences that contest producers' discourse in some way or other.

One section of the mass media whose power has been widely debated is the news media, and there is much controversy over the extent to which, and ways in which, news discourse shapes the beliefs and actions of audiences, but broad agreement that it has some significant effect. The central issue is what might be called 'signifying power': if it is assumed that there is no neutral or objective way of representing events, then all reports signify them in particular ways, perhaps according to the strategies (economic, political) and ideologies (see *Ideology*; and Sect. 3.1 below) of the reporter. For example, the headline *Police shoot 100 in riot* is quite explicit about the agency of, and responsibility for, the violence reported, whereas the headline *100 die in riot* is quite inexplicit, and there may be good strategic or ideological motivations for one rather than the other. What is not entirely obvious is who exercises signifying power in the media: behind the journalists and editors are the powerful sections of society

(government, industry, the professions, etc.) that constitute the major sources of news, and it is arguable that events are often signified in ways which accord with their interests, strategies, and ideologies. Their power is a hidden power, which might be related to a 'hidden agenda' for the media: to mediate between those who hold power and the mass of the population. Signifying power in the media may be used to consciously manipulate audiences and readerships (see *Manipulation*). A more general and perhaps more insidious effect of signifying power is that particular signifying practices with particular ideological investments become naturalized for media professionals.

3. Power Behind Discourse

'Power in discourse' draws attention to discourse as one site where domination takes place and power relations are enacted; whereas 'power behind discourse' identifies discourse itself as a target for domination and hegemony. Societies and their constituent institutions (e.g., education, health care, law) have 'orders of discourse'—sets of codes, conventions, and norms which are structured in relation to each other in particular ways, and which are open to restructuring. Orders of discourse can be regarded as one domain of cultural hegemony (see *Hegemony*): dominant groups in societies and institutions seek to win consent for particular structurings of orders of discourse, as part of their attempt to achieve hegemony in the sphere of culture (complementing economic and political hegemony).

One dimension of a society's order of discourse is the structuring of relationships between different languages, and different varieties (social dialects—see *Dialect and Dialectology*) of one language. Certain languages or varieties are typically attributed high prestige and designated as appropriate for prestigious functions in law, government, education, and so forth, whereas other languages or varieties may be marginalized by being designated as appropriate only for functions in the private and domestic spheres, or indeed may be excluded through bans or ideological offensives (see *Linguicide*).

'Language standardization' is the process through which one variety of a language becomes the 'standard language' of a society, or even a broader international community—'Standard English' is an example. Standard English developed from the East Midland dialect of the late medieval period, which became the language of the merchant class of London, the class which was to achieve dominance in the transition from feudalism to capitalism. This link between the standard and social class is still there, although its form has changed: it is upper-class and middle-class children who learn Standard English as their mother tongue in the home, and for whom it constitutes the most efficacious 'cultural

capital'—a passport to positions of influence and power. The claims of Standard English to be a national language are, it is true, recognized by all sections of British or American society, but it tends to be a forced and superficial recognition on the part of working-class people and cultural minorities, who still adhere strongly in practice to their own varieties and languages (see *Class and Language*). Standard English is universally taught in the school system, yet a substantial proportion of children fail to achieve high levels of competence in it. The process of language standardization does not merely elevate one variety, it simultaneously demotes others, and imposes a structuring upon the societal order of discourse which marginalizes 'nonstandard' varieties and other languages (see *Linguistic Imperialism*). Standardization belongs to the era of the modern nation-state with its centralization of national economies, political systems, and cultures. As this era comes to an end, nation-states are simultaneously under pressure from larger international entities and smaller local entities, and so too is the position of standard languages within orders of discourse.

As the last paragraph suggests, power behind discourse is not only a question of securing hegemonic structuring of orders of discourse, it is also a question of controlling access to languages, varieties, and codes which are ascribed prestige within orders of discourse. The educational system is of considerable importance in controlling access, being as Foucault put it 'a political way of maintaining or modifying the appropriation of discourses, along with the knowledges and powers which they carry' (1984: 123). Whatever the political rhetoric of education, the effect of the schools in Britain, for example, has been to consolidate class differences in 'linguistic capital' established in the family, rather than ironing them out. Access to prestigious functional varieties or 'registers' such as varieties of writing (literary, scientific), professional varieties such as legal English, or genres such as interview or public speaking, is similarly filtered by the education system. This is not to say that working-class or cultural-minority children do not acquire them, but that the development of high degrees of competence in them is disproportionately weighted toward upper-class and middle-class children.

Another important aspect of power over orders of discourse is the shaping, imposition, and naturalization of particular variants of the functional varieties just referred to. For example, there are various ways in which medical consultations might be and indeed are conducted, but there has tended to be an approved way of conducting them which has been institutionally 'policed' through inducements, pressures, and sanctions. A particular way of conducting a medical consultation will involve a given distribu-

tion of discourse 'rights' and 'obligations' between doctor and patient, such as rights and obligations to take turns at talking (see *Conversation Analysis*), respond to the other's turns in particular ways, develop and change topic, probe into aspects of the other's private life through direct or more tentative questioning, provide summaries of what has been said, give accounts of illnesses and problems, and so forth. What participants are allowed or required to do, and inequalities between participants in this regard, point to implicit assumptions—ideologies—about the nature of medicine, what it means to be a doctor or a patient, what relationship there ought to be between doctor and patient, and so on.

One may say that particular practices of medical consultation, classroom teaching, or interaction between managers and workers, carry particular ideological investments (see *Ideology*). That is, they embody sets of assumptions which correspond to the interests and points of view of particular social groups, but are made to look like mere common sense. This is why the imposition of particular practices is an objective for power holders: they can progressively naturalize ideological assumptions which help reproduce existing social relations and structures. Ideology is one modality of power, which uses control of meaning and definition of common sense as a means of producing and reproducing domination, positioning people as 'social subjects' of various sorts, and underpinning the interpretation of language texts as 'coherent' (see Sect. 3.1). The other major modality of power is the use of force, which may have more immediate effects than ideology, but is less effective in the longer term in maintaining relations of domination. Modern societies, in which domination takes the form of hegemony (i.e., rule through the generation of consent—see *Hegemony*), have become increasingly reliant upon the modality of ideology. They have therefore become increasingly reliant upon discourse, because it is in discourse that ideological processes mainly take place.

3.1 Ideology

Ideology, like power, is a complex and contested concept. It is a central element of Marxism, where ideologies have traditionally been seen as misrepresentations of reality through which the ruling class dominates other classes. Outside Marxism, more general definitions have emerged which see different ideologies as merely different perspectives or points of view. But the power of ideology as a concept is the connection it makes between domination and points of view, meanings, and representations. This link between ideology and domination has been maintained and developed in more recent Marxist theory (see *Marxist Theories of Language*). One influential tradition, based upon the theories of Antonio Gramsci (see *Gramsci, Antonio*) and Louis Althusser,

sees ideologies as: (a) generally implicit or 'common-sense' assumptions about the nature of the world, social relationships, and social identities, which (b) invest and shape social practices, including discourse practices, that constitute their material form, and which (c) contribute to reproducing or restructuring relations of domination ('power over'). Most studies of language and ideology have adopted a view of ideology along these lines.

Language texts, written or spoken, may be ideologically 'invested' in various ways and at various levels—that is, choices of vocabulary, grammar, organization of trun-taking, and so forth, may come to be ideologically significant. Words and their meanings have received most attention, on the assumption that contrasting ways of 'wording' (see *Pragmatics and Sociolinguistics*) a particular domain of experience may embody different ideologies. An example would be the contrast between more traditional wordings of educational practices, and current 'commodified' wordings (e.g., *we can offer our customers a range of purpose-built packages to choose between*). But aspects of grammar may also be ideologically invested—compare, for example, the sentences *Thousands are out of work* and *Company directors have sacked thousands of workers* as different ways of reporting the same event (e.g., redundancies in the car industry). The former is an intransitive sentence without an agent which represents a state, the latter is a transitive sentence with an agent which represents an action. Systematic selection among such alternative sentence types may be connected with representations of unemployment as a condition which nobody is responsible for, or alternatively as caused by the actions of specific agents. On a different level of analysis, the turn-taking system operative in a classroom, or the politeness conventions (see *Politeness*) operating in interaction between managers and workers, may be invested with particular ideologies of education and work. Other features of texts are also ideologically important, including the sorts of metaphor that are used, and the sorts of presupposition that are made.

To understand fully the ideological effects of discourse, however, it is necessary to consider the processes of producing and interpreting texts as well as the texts themselves. In this connection, Althusser's emphasis on the relationship between ideology and the constitution of social subjects is important. He claims that ideologies 'interpellate' individuals as subjects of particular sorts, placing them in particular subject 'positions.' Discourse plays a major part in such processes of interpellation. For example, one effect of a set of conventions for medical consultations or classroom teaching is to cumulatively construct definite identities and 'positions' for doctors, patients, teachers, and pupils. If such a set of conventions comes to be dominant and natur-alized (a matter of common sense), individuals who wish to become doctors or teachers have to compliantly occupy the positions provided. When a doctor addresses a patient drawing upon such conventions, (s)he implicitly positions the patient through the way (s)he speaks, and the same is true vice versa. Those so positioned may resist these positionings, but it is often extremely difficult to do so. Compliance does not however entail acceptance: people may 'go through the motions' of adhering to conventions, while at the same time privately distancing themselves from them. In favorable circumstances, they may challenge and try to restructure them (see Sect. 4).

At the end of Sect. 3, a connection between ideology and the production of coherent interpretations for texts was referred to. 'Coherence' has been a major concern of discourse analysts, because a central question about discourse is how interpreters can make sense of written or spoken texts which on the surface are highly disjointed and incoherent. However, from the perspective of ideology and the subject, the production of coherent interpretations can be seen as a key moment in the positioning of subjects. In order to establish coherence, interpreters need to draw upon the sort of implicit assumptions and knowledge structures which cognitive psychologists and specialists in artificial intelligence have called 'scripts,' 'frames.' and 'schemata.' Suppose, for instance, that a text contains this sequence of sentences: *She's giving up her job next week. She's pregnant.* To link the sentences coherently, an interpreter needs a 'bridging' assumption, that women who are about to have children stop working. It is an ideological assumption, tied to particular (now contentious) views of gender relations in the family. The point is that in achieving a coherent reading of the text, the interpreter is simultaneously being positioned, or repositioned, within a particular ideology of gender relations which (s)he needs to take for granted in making the next coherent. Similar comments apply to text producers: producing a text is an achievement which rests upon the mobilization of ideological assumptions and knowledge structures, thus ideologically positioning the producer.

4. Power Struggle In and Over Discourse

The view of power in and over discourse which has been presented so far is too static, and overemphasizes the imposition of domination from above. It neglects ways in which power may be contested. This section will adopt a more dynamic conception of power in and over discourse, centered around the concept of power struggle.

4.1 Struggle in Discourse

The exercise of power in discourse frequently meets with resistance, though only under particular

subjective and social conditions. In terms of the former, resistance presupposes participants who have the motivation, resources, and confidence to resist. These subjective conditions are often discussed in terms of the 'empowerment' of members of dominated social groups (be it workers, women, or members of cultural minorities). Empowerment can be thought of as educative action to equip people to make use of the power they have—using 'power' now in the more general sense of transformative capacity—to resist in circumstances of domination. But empowerment can be effective only under favourable social conditions: resistance in discourse is more likely to occur, and more likely to take active forms, in institutional locations where the domination of one group over others is partial, precarious, or contested.

Struggle and resistance in discourse take a variety of forms, some of which are more active than others. It was suggested earlier that compliance with dominant discourse practices may amount to no more than 'going through the motions.' A form of passive resistance which may be as much as is possible in certain circumstances. Participants may also resist by fully exploiting the rights made available to then within dominant discourse practices, rather than challenging those practices (e.g., the right of interviewees to question interviewers, which is often offered to them at the end of an interview in the expectation that they will make at most token use of it). Or participants may overtly question the practices themselves; I could, for example, under certain circumstances tell my doctor that he might learn more about my problems if he sat back and listened to me for a while, rather than submitting me to a battery of diagnostic questions. A more covert and more pervasive form of resistance is not conforming with the rights and obligations imposed by dominant discourse practices, and drawing instead upon other practices. For example, provided (s)he has the resources to bring it off and provided the social conditions are favorable, a lower-status participant may be able to prevent a higher-status participant from conducting an interaction as a formal interview by talking (and more generally acting) as if it were a friendly chat.

4.2 Struggle over Discourse

Such forms of struggle in discourse may be manifestations of longer-term processes of contestation between social groups in which the structuring of societal and institutional orders of discourse is at stake. In Sect. 3 the imposition of hegemonies from above was referred to, but hegemonies are also open to challenge from below, and must constantly be reproduced and redefined under conditions of struggle. An example of the challenging of hegemonies from below is the attack by feminists upon what are seen as sexist and male-dominated discourse practices across a range of institutional orders of discourse—in the family, politics, trade unions, the media, education, social services, and so forth. One focus of this attack has been the forms of female–male interaction referred to in Sect. 2, which constitute modes of male domination: forms of conversation, for example, in which women are kept in the marginal and passive roles of listener and respondent, where their contributions are interrupted, where they are expected to talk on men's topics without being able to introduce their own, and so forth. The feminist challenge has made hitherto hegemonic practices problematical for many men as well as women, and led to some restructuring of practices.

Another example is the widespread tendency for institutional discourse (e.g., interviews of various kinds) to become more informal and conversational, less directive and judgmental and more empathetic, sometimes drawing upon the discourse of counseling as a model. This tendency is associated with struggle against traditional authoritarianism and bureaucratic impersonality in relationships between professionals and their clients or publics, and the late twentieth-century ascendancy of values of individualism and consumerism. But this tendency illustrates how challenges from below may be contained and appropriated from above: these new forms of institutional discourse are now widely cultivated by professionals and managers as strategies for attracting clients and consumers, or in personnel contexts for increasing the commitment of employees to the firms they work for, and making a greater range of their skills and talents available for exploitation by the firm. This can be seen as a shift in ideological investment (see Sect. 3.1): the concept of ideological investment implies that a given set of discourse practices or linguistic features does not have one inherent and permanent ideological value, but may come to be differently invested in different contexts, in the course of ideological struggle.

This example points to a basic feature of power struggle over orders of discourse in late twentieth-century society. On the one hand, there are centrifugal tendencies. Modern industrial society has been associated with the imposition of homogeneous and unitary dominant practices for such types of institutional interaction as medical consultations, job interviews, teacher–pupil interactions, or the discourse of managers and workers. There is now a shift away from this, associated with what some see as a 'postmodern' fragmentation of the modern structuring of society into discrete institutional and professional domains. Discourse practices are becoming more heterogeneous, partly because there are more opportunities for challenges from below to have effects. So the practices of medical consultation or classroom teaching are now highly variable,

allow-ing the preferences and dispositions of doctors and teachers, patients and learners, to find some expression.

On the other hand, however, there are centripetal tendencies. These may be partly in response to the above centrifugal tendencies, but they also give them fresh impetus. Thus centripetal and centrifugal tendencies are tied into a single dialectic. Late twentieth-century centripetal tendencies involve a process of 'technologization' of discourse: the subjection of discourse practices (e.g., various types of interview) to systematic and institutionalized processes of research, redesign, and training. The technologization of discourse is a form of linguistic manipulation (see *Manipulation*). But as suggested above, these impositions from above may generate resistance and moves toward further diversity (see also *Linguistic Imperialism*; *Discourse*).

5. Conclusion

Absence of serious attention to the relationship between language and power is a major weakness of linguistic theory in the late twentieth century, including much of the work that has been done in sociolinguistics. In the 1960s, a distinction was often drawn between two branches of language study which link language and the rest of society in different ways: sociolinguistics, which places the focus upon language; and 'sociology of language,' which starts from society and social theory. This distinction has dropped out of fashion, and sociology of language has not really developed. The time has come for 'mainstream' linguistics to take note of recent critical work on language and power, perhaps in the form of resurrecting the sociology of language. But work on language and power may have a deeper significance for mainstream linguistics in the longer term: it may lead to new, more socially realistic theories of language which displace currently dominant asocial theories in the center of the discipline.

Power Differentials and Language

P. L. van den Berghe

Nearly all human relationships have a power dimension, and are, of course, expressed, to a large extent, through language. It follows that language frequently reflects, maintains, and enforces power differentials (Laponce 1984, Pool 1987). Of the major types of unequal relationships, those involving people of different 'race' or ethnicity, including the special case thereof known as 'colonialism,' have vied with age, sex, and social class in importance (Banton 1983, Horowitz 1985, van den Berghe 1981). This article is an attempt to sketch some of the main sociolinguistic features of ethnic interactions, with the main analytical focus on power and inequality.

1. Linguistic Differentiation

Speech communities, by definition, emerge from sustained, iterated linguistic interaction. Conversely, barriers of any kind to interaction inevitably translate into language barriers. Uninhibited, spontaneous, free and easy speech is only possible to the extent that barriers are absent. The most obvious barriers are those of physical distance. While they are partially breached in recent decades by the telephone, the radio, and television, it continues to be true that language is shaped primarily by people interacting face to face with high frequency, that is, by people in spatial propinquity to one another. Regionalism is, thus, a salient source of linguistic differentiation.

However, while spatial propinquity is a necessary condition for the formulation and maintenance of a speech community, it is not a sufficient condition. Barriers of social status frequently interfere with interaction as well. Age and gender are ubiquitous barriers of social status which lead to linguistic

differences. Both sex and age differences are deeply ingrained in the lexicon and even syntax of many languages, leading, for example, to asymmetrical forms of speech between juniors and seniors. Beyond these asymmetries in common speech, when barriers to interaction between age groups and men and women are rigid, linguistic differences between these groups may even emerge. This is particularly pronounced between generations. As language continuously evolves, children often use a different lexicon and even syntax than their parents. Furthermore, children will frequently use different language varieties to their age mates than to their elders.

Social class is another prominent dimension of linguistic differentiation. To the extent that people of different class origins are prevented from having free and open relations with one another, they develop different forms and styles of language use. The more rigid a country's class structure, the more evident linguistic differences become. If class status (including, notably, occupation and access to various types of schooling) is largely ascribed and inherited, class groups readily become socially isolated and quickly turn into speech communities. Even without sharp class barriers in the conventional sense, occupational segregation readily produces that effect: lawyers speak differently from army officers, physicians, sailors, or musicians.

2. Language and Ethnicity

The link between language use and ethnicity is especially close. In the last analysis, an ethnic group (or ethny) is a group that defines itself and is defined by others as descended from common ancestors (van den Berghe 1981). Common biological descent, however, is often difficult to prove; indeed, it may be partly fictitious. Common ethnicity is frequently operationalized in terms of language. One is a Dane if one speaks Danish, at least if one speaks it well enough to pass as a native. The reason why language is such a good criterion of ethnic membership is that our biological programs for language learning lose enough flexibility early enough in life to make it difficult for an adult to learn to mimic the phonetics of a second language. Historically, if one spoke a language others thought to be flawless and accentless, the odds were quite high that one was a native member of the language group. Massive long-distance migration in recent centuries, and consequential intermarriage, have considerably muddied ethnic and linguistic boundaries, and the picture has been further blurred by 'racial' barriers, but, by and large, ethnic and linguistic communities still coincide frequently enough for language use to remain the main marker of ethnicity.

It is true, of course, as Eastman (1983) points out, that there can be a dissociation between language use and even language competence on the one hand, and ethnic identity on the other hand. Learning to become a relatively competent user of a second language does not mean shedding one's ethnic identity and assuming a new one. Language can be, and frequently is, learned, used, and manipulated to instrumental ends more quickly than ethnic identities change. At the limit, one can even totally cease to use one's native language and one's children may never learn it, without the family losing, even for generations, a sense of ethnic identity with the ancestral group. A measure of dissociation between ethnicity and language is most characteristic of countries like Canada, Australia, Argentina, Brazil, and the USA, that have experienced a massive and recent influx of immigrants from many ethnic origins. Thus, in the USA, people may call themselves Japanese, Italians, or Mexicans even though they are no longer fluent in their respective 'home' languages. These cases are rather exceptional, however. In most of human history, and still in the early twenty-first century in most of Europe, Asia, and Africa, ethnicity and language overlap closely.

Ultimately, it is the degree of endogamy which maintains both ethnic and linguistic boundaries. As has been seen, ethnicity is self-defined in terms of common descent. Therefore, mixed ethnic descent, by definition, creates marginal categories of individuals who straddle ethnic groups. Unilineal descent societies, i.e., those that are clearly patrilineal or matrilineal, sometimes resolve that problem by ascribing the offspring to the group of the socially relevant parent (the father or the mother), but such assimilation only 'works' if it is accompanied by complete linguistic absorption. In practice, ethnic intermarriage rates in excess of 25 percent give rise to great fluidity and mixing of ethnic and linguistic boundaries.

3. Language and Power in Ethnic Relations

So far, language and ethnicity have been discussed without reference to power differentials existing between linguistic and ethnic groups. In fact, power differentials are almost always present between ethnic and speech communities. To a large extent, it is the nature and source of power differentials between groups which determines their interrelations and their linguistic behavior. Therefore, power is central to any sociolinguistic analysis. A language has been defined as a dialect with battleships (see *Language; Dialect and Dialectology*).

There are several dimensions to power differentials between ethnic and linguistic communities.

(a) Absolute size of the group worldwide. Holding everything else constant, the larger a language group is, the better are its prospects for long-term survival, and the better its position relative to other groups. This is true even if the group in question has few speakers locally.

Thus, for instance, the future of English in India is better than that of Dutch in Indonesia, even though both languages were spoken by small dominant minorities in these respective countries. Both languages were introduced by a dominant colonial power, which lost political control simultaneously. Yet, English is still an important medium of communication in India, while Dutch has virtually ceased to be used in Indonesia. The incentive for a member of the Indian elite to learn English remains much greater than for his or her Indonesian counterpart to learn Dutch. English is spoken by some 360 million native speakers, accounts for some 65 percent of the scientific literature in chemistry and 73 percent in medicine, controls 34 percent of world GNP, and 32 percent of the world's military budget. Dutch, by contrast, is spoken by 20 million people, produces 0.1 and 0.3 percent of the scientific output in chemistry and medicine respectively, accounts for 1.3 percent of world GNP, and 0.9 percent of the world's military budgets (Laponce 1984; chap. 3).

(b) Geographical distribution of speakers. Other things being equal, the more geographically scattered a group is, the better are the chances of diffusion and survival of its language. Thus, despite its enormous number of native speakers, and the appreciable military power of the People's Republic of China, Mandarin is a much less vital international language than English, or even French and Spanish. Similarly, Japanese has more native speakers than French, and Japan is the world's number two economic power, but hardly anyone outside Japan speaks the language. Internationally, even Portuguese or Dutch will get one farther than Japanese.

(c) Relative size of the language group in the population of a state or territory. Barring differences in power or wealth between groups, the larger a language group is in relation to other groups, the more useful its language is to others and the more it is likely to be used, and to spread. A French- or Italian-speaking Swiss citizen, for example, has most incentive to learn German as a second language, and least to learn Romansch. Language learning is always costly to the learner; therefore, the amount of learning of any language is proportional to the benefits the learning confers. The simplest model predicting language learning is utilitarian: people, even young children, pursue a conscious or unconscious cost–benefit calculus in their language behavior, as indeed they tend to do in all their behavior. An occasional individual learns languages for the sheer intellectual fun of it, but that behavior is rare enough to be inconsequential in the aggregate.

(d) Control of a linguistic or ethnic group over scarce resources. The most important of these resources are political power and wealth, one being frequently convertible into the other. Languages along with other cultural products such as religion, diffuse overwhelmingly through conquest and trade. The incentive for the poor and the powerless to learn the language of the rich and the powerful is much greater than vice versa. Indeed, the incentive can be so overwhelming where disparities of power and wealth are great (as under colonialism), that the language of a small dominant minority of 1 or 2 percent can quickly displace majority languages. The spread of Spanish in the wake of the conquest of the Western Hemisphere is a good case in point. Within half a century of the *Conquista*, the language of a few thousand Spaniards was well on its way to becoming that of half a continent.

(e) In addition to power differentials, one additional factor affects whether languages spread, stagnate, or decline, namely: degree of contact between linguistic and ethnic groups. Highly isolated communities, however small, poor, and powerless, can indefinitely maintain their language provided that their isolation persists. Thus, for instance, scores of very small Amazon and Orinoco basin groups held their own for several centuries beyond the frontier of Spanish and Portuguese settlement so long as they remained inaccessible. Conversely, the language of large, powerful, and wealthy groups can fail to spread if states pursue isolationist policies. The cases of Japan and China until the late nineteenth century are good examples.

In sum, a few key factors, in combination, provide good predictors of linguistic behavior. They do so because they are all readily reducible to a simple utilitarian and individualistic model of human behavior. We know that the human brain is extraordinarily adept at acquiring one complex language very early in life. We also know that language learning ability declines with age (though not equally for everyone), and that the cost–benefit ratio of learning additional languages tends to rise steeply with age in most circumstances. Multilingualism is not a normal state of affairs because it is quite costly. Most people only learn second or third languages if the benefits of doing so outweigh the costs. Conditions that affect the cost–benefit ratios of language learning are relatively simple and straightforward. Basically, they have to do with disparities of numbers, and of control over scarce resources, mediated by probability of contact. The latter, in

turn, is partly a function of spatial distribution and isolation.

Sociolinguistic situations prevailing in different types of ethnic contact will now be discussed.

4. Slavery

A common feature of slavery is that slaves are strangers to their masters. They are generally acquired from neighboring groups, through warfare or purchase. Often, they come from a multiplicity of ethnies, and thus, are a linguistically fragmented group compared to the rest of their 'host' society. Despite great differences in status, wealth, and power between masters and slaves, the two groups often live in 'distant intimacy,' i.e., they are socially distant but spatially (and often emotionally) close. All these conditions of linguistic fragmentation, powerlessness, and spatial proximity insure that the slave will quickly assimilate to the master's language and culture. Learning the master's language is advantageous both to the master and to the slave. For the master, it makes the slave more useful. For the slave, it helps him make the best of a bad situation, by ingratiating himself to his master or manipulating him. Almost invariably, the burden of learning a new language is on the subordinate. Since masters will not make the effort to learn the language of their slaves, it is almost always the slaves who acculturate to their masters' language and customs.

In the case of domestic slavery, where slaves live in the household of their masters, and, in the case of women, frequently bear their masters' children, slavery is, in fact, frequently a transitory condition. The institution of slavery persists, but individuals move out of slavery in one or two generations through acculturation and interbreeding. Slaves become serfs or freedmen.

In the rarer situation of chattel slavery, which prevailed in the USA, Brazil, the Caribbean, and Spanish America, slave status was racialized (i.e., associated exclusively with black African descent), and was accompanied by an exceptionally harsh and rigid social order. Furthermore, field hands on large plantations did not have close day-to-day relations with their masters. Only an elite of house slaves did. Yet, even in the Western Hemisphere, African slaves had to learn English, Spanish, Portuguese, French, or Dutch, as the case might be. They had little option as their masters' language was the only lingua franca not only to communicate with their masters, but also to talk to one another. Coming from scores of different African societies, they had no common language.

However, conditions of chattel slavery not only forced linguistic acculturation on slaves, they also interfered with the slaves' ability to acquire a full version of their masters' language and culture. Harsh physical conditions, the disruption of families, high

mortality and turnover, social barriers, racial segregation, and enforced illiteracy all made it difficult for the slave to acquire the master's language. The result was frequently, for the initial period of contact, the emergence of pidgins, which, after one or two generations, evolved into creoles. The French-based creoles of Haiti, Martinique, and Guadeloupe are good examples of this process (Stewart 1962).

Scholarly and political arguments have long raged as to whether Afro-Americans (and by extension, Afro-Caribbeans, Afro-Brazilians, and Afro-Hispanics) speak distinct languages from their compatriots of European descent. The issue of 'survival' of African languages and cultures in the Western Hemisphere is complex, and there is a lot of local variation. Two areas stand out in terms of a large African contribution to contemporary language, cuisine, religion, and other aspects of culture, namely Haitic, where the Dahomean component is clear, and north eastern Brazil (especially Bahia), where Yoruba influence is obvious.

In the USA, evidence for African survivals is much more tenuous, except in the cultural isolate of the islands off the South Carolina coast, where some linguists have claimed that Gullah is a creole (Hancock 1971). There is also much controversy concerning the classificatory status of African American Vernacular English (AAVE), but most linguists agree that it is a form of English rather than a creole. It has a regional (Southern) and class component, as well as a specifically 'racial' one. Furthermore, many American do not speak AAVE, and most of those who do exhibit large degrees of diglossia. They can switch with relative ease between their dialect and Standard American English, perhaps even more readily than many white speakers of non-standard dialects, e.g., from rural Kentucky or Maine.

5. Language and Race

The real issue about AAVE, however, is not the extent to which it is spoken by African Americans, nor the degree to which it varies from Standard American English (if, indeed, there is such a thing), but the stigmatization attached to the speech behavior of the black lower class (Sonntag and Pool 1987). AAVE is doubly stigmatized on the basis of class and race, and that stigmatization is a powerful component of racial discrimination in contemporary American society (in such matters as educational and occupational opportunities). African Americans are routinely expected to master Standard American English in order to have access to formal education and to all but the most menial forms of employment. Language use associated with blacks is much more powerfully stigmatized than equally variant forms spoken mostly by whites. These linguistic prejudices thus reinforce racial discrimination and vice versa.

The case of AAVE is but one of the many instances where differences in language use overlap with racial distinctions in a given society. Another case of a postslavery situation is Haiti. During slavery, a sharp distinction evolved between a 'mulatto' class of freed slaves who, through close contact with the white slaveowning elite, came to speak a Haitian variety of standard French and later to rule the country after the revolution of 1791, and the mass of black slaves who developed a French-based creole. The sharp class and linguistic distinction persists in the early twenty-first century, even though there is extensive diglossia in the upper and middle classes. The official language is standard French, which is the passport of admission to the ruling class, but the native language of 80 to 90 percent of the population is a distinct creole, derogatorily referred to by the mulatto elite as a mere patois.

Unlike AAVE, which is clearly a variety of English, Haitian creole is sufficiently distinct from French in both lexicon and syntax to qualify as a separate language. Haitian creole, for instance, is more clearly distinct from French than Afrikaans is from Dutch. Afrikaans, however, was, until 1994, the language of the powerful white ruling class of South Africa, and was an official state language with an extensive literature, while Haitian creole is spoken by impoverished peasants and is seldom written (except in folkloric novels and anthropology monographs). Afrikaans, in short, had an army behind it, and was universally recognized as a separate language. Since the advent of non-racial democracy in 1994, however, the status of Afrikaans though still official has been greatly reduced relative to English. Haitian creole is the language of the oppressed and lacks even a distinct name.

'Racial' groups only exist insofar as physical phenotypes (such as skin pigmentation, hair texture, facial features, and the like) are attributed social significance in a particular society. Where such is the case, racial groups may or may not be culturally and linguistically distinct as well. Racially stratified societies are overwhelmingly the product of large-scale long distance migration across wide phenotypic gradients (van den Berghe 1981). This may happen through conquest as in much of Africa, Asia, and America, or through labor migration (in the form of slavery, indenture, or free labor).

Sometimes, these socially defined groups are also ethnic groups. More frequently, racial groups are made up of many ethnies. Not uncommonly, after centuries of close contact, members of different racial groups may, in fact, share the same language and culture, as is true, for instance, of white and black Anglophone North Americans, and of white and 'colored' Afrikaans-speaking South Africans. Even when different racial groups share a common language and culture, however, the stigma of race itself perpetuates sufficient discrimination and social segregation to maintain great inequalities of status, power, and wealth, and, thus, to create subcultural and dialectal differences between racial groups. These secondary linguistic and cultural distinctions are no different in principle from those that arise between social classes, except for the peculiarly invidious stigma of race itself. Once the stigma of race is entrenched in a society, then any differentiation, however objectively trivial, between racial groups becomes itself stigmatized. It is this element of seemingly intrinsic stigmatization which distinguishes racial from mere ethnic distinctions. Ethnic distinctions are not intrinsically demeaning in the way that racial distinctions inevitably seem to be in those societies that make them (see *Ethnicity and Language*).

6. Imperialism

If imperialism is defined simply as the conquest and rule of one ethny over others, then it follows that imperialism is inevitably accompanied by linguistic stratification. The language of the ruling class has prestige, and spreads at the expense of the other languages because fluency in it confers obvious economic and political advantages. However, linguistic hegemony, especially when it is forcibly imposed by discriminatory practices, frequently arouses opposition in the form of nationalist movements. In short, imperialism is almost invariably accompanied by conflicts which have an important linguistic dimension. Perhaps the most common case is one where one ethny uses its own language as the official language of the state it controls, to the greater or lesser exclusion of all other languages. Classical examples are the use of Russian in the Czarist Empire, of Osmanli Turkish in the Ottoman Empire, of German in the Hapsburg Empire, and of Amharic in Ethiopia.

6.1 Definitions and Distinctions

The linguistic hegemony of the *Staatsvolk* (as the Germans call the ethny that dominates the state) can range from a situation of official tolerance of other languages to active suppression. At one extreme, for instance, all nondominant languages may be excluded from all formal education, from law and administration, and even from public discourse outside the home, and they may be denied access to the printed word and to all public media. Conversely, the dominant language is actively pushed through the schools, the press, the mass media, the courts, the military, and all other organs controlled by the state. Such extreme cases of forced assimilation frequently provoke countervailing nationalist movements. Most imperial ruling classes have, therefore, pursued somewhat more flexible linguistic policies of tolerating the use of other languages, but of simply

601

withholding state-controlled resources from them. Access to the elite, for instance, can only be achieved through mastery of the dominant language. Such relatively 'tolerant' policies have frequently had a double benefit for the *Staatsvolk*: its language spread rapidly because of the benefits mastery of the dominant language conferred, but linguistic policies of laissez-faire and benign neglect prevented the growth of militant nationalisms.

Colonialism is really a special and extreme case of imperialism. Although both definitions and situations of colonialism have varied, the term has generally meant the political and economic hegemony of one state over distant territories inhabited by culturally and 'racially' distinct populations, often much poorer groups with a less developed technology. Such situations made not only for maximum cultural and social distance between conquerors and conquered, but also for sharp inequalities in wealth and power. Indeed, these inequalities in access to scarce resources have often been so large as to enable ethnic minorities of 1 percent or less of the total population to dominate the rest. A few thousand British civil servants, army officers, railway engineers, etc., ruled 300 million Indians, for instance. The same was true of the Dutch in Indonesia, the Belgians in the Congo, the French in West Africa, and so on.

A distinction is frequently made between 'colonies of settlement' like North America, Australia, and New Zealand, and 'colonies of exploitation' like most of tropical Africa, Asia, and Latin America. Colonies of settlement were largely nontropical lands suitable for European settlement, where native populations were so sparse as to make their virtual extermination a likely prospect. Where the native population was dense and had achieved a complex level of social organization, colonies of exploitation resulted, especially in tropical areas unsuited to the biological reproduction of European populations. Would-be colonies of settlement with large native populations (like Algeria, South Africa, Rhodesia (now Zimbabwe), or Angola) had very mixed success in terms of permanent European colonization.

Linguistically, the colonial expansion of Europe covers a wide gamut of situations. Most of the successful English colonies of settlement—Australia, New Zealand, and what became the USA—became effectively monolingual in English, thereby assuring the pre-eminent position of English as an international language since the nineteenth century. The English monolingualism of these countries was the result of massive displacement and reduction of native populations through epidemics, habitat destruction, land expropriation, and military conquest, and of fairly rapid linguistic assimilation of millions of non-English speakers from Europe, Asia, Africa, and Latin America, first under slavery, later under voluntary immigration. Canada's linguistic evolution

is somewhat similar, except for its sequential colonization by the French and the British, and, thus, for its stable bilingualism in the respective areas of French and English settlement.

6.2 Latin America

Latin America is also an area where the respective colonial powers—Spain and Portugal—were remarkably successful in imposing their language. In the 'Southern Cone' (Argentina, Chile, and Uruguay), this is not surprising, because the native population was sparse and largely decimated, as indeed was also the case in much of the Amazon and Orinoco basins and the Caribbean. In Mexico, Central America, and the Andean countries, however, the indigenous population was dense, and, although it was also decimated by conquest and epidemics, large concentrations of 'Indians' survive to this day. In tropical American countries, Europeans always remained small minorities, but they interbred extensively with aborigines and African slaves to produce Spanish- or Portuguese-speaking populations of mixed ancestry, a process known in Spanish America as *'mestizaje.'*

In contemporary Mexico, barely one tenth of the nation's citizens still speak indigenous languages (and most of them are bilingual in Spanish), even though something like 85 to 90 percent of Mexicans are of at least partly indigenous descent. In North America, only Guatemala still has a large number (some 3 million) of monolingual speakers of native languages (specifically, 22 Maya languages). There is also a large pocket of some 12 million Quechua and Aymara speakers in the high Andes of Ecuador, Peru, and Bolivia. In addition, large areas of lowland jungle in Brazil, Venezuela, Peru, Ecuador, and Bolivia are sparsely settled by a multiplicity of tiny language groups of *selváticos*, 'forest Indians.'

Paraguay is a special and unique case in Latin America, in that it is officially bilingual in Spanish and Guaraní. Many Paraguayans at all class levels are effectively bilingual, a situation which also prevails in some Andean areas of Peru (with Quechua and Spanish). In both of these areas, in fact, the upper classes tend to be more bilingual than the lower classes. This is an extremely uncommon situation created by Catholic (especially Jesuit) evangelization in a standardized form of Guaraní and Quechua, respectively. These indigenous languages were thus actually spread by the agents of the colonial power, and acquired by many members of the ruling class. The end result was an Indian peasantry monolingual in the native language, and bilingual, urban middle- and upper-class mestizos.

With the exceptions noted above, however, Spanish and Portuguese in their respective areas nearly totally displaced indigenous languages. Given the diversity of cultural origins of the Latin American population and the enormous geographical area it

covers, the degree of linguistic uniformity it has achieved is highly unusual. A brutal conquest, followed by devastating epidemics, slavery, and peonage explains the linguistic dominance of the conquerors during the colonial period. The independent republics which followed were dominated by the Spanish- and Portuguese-speaking upper classes which established centralized governments that used exclusively Spanish and Portuguese as languages of administration, education, justice, finance, commerce, and industry, and thus condemned the indigenous languages to growing marginality and disuse.

6.3 Africa and Asia

In contrast to the extensive penetration of the European languages in the Western Hemisphere, European colonialism made little linguistic headway in Africa (except in South Africa), and even less in Asia (except for Israel). The linguistic situation of Israel is quite unique. Jewish settlers from a score or more of European, African, and Asian countries revived a moribund religious language and transformed it into the mother-tongue of nearly all Sabra (Israel-born Jews) in a generation or less. There have been other state-supported attempts to revive 'national' languages, as with Irish in Ireland, but Israel is the only clear-cut success story.

In South Africa, until 1994, the 15 percent white minority imposed the use of their two languages, English and Afrikaans (a Dutch creole), on the rest of the population. Perhaps another 10 to 15 percent (mostly 'coloreds,' or people of mixed descent) became monolingual or bilingual in these two official languages, and millions of black South Africans use one or both of them in addition to their first language. Indeed, South Africa probably exhibits one of the highest degrees of effective multilingualism of any country on earth. It is not uncommon for urban black Africans to speak, in addition to their native Bantu language, both of the European languages with some fluency, and one or two of the closely related Bantu languages besides their own. As is true in most colonial situations, bi- or multilingualism is much more extensive in the formerly subordinate groups than among members of the former ruling oligarchy.

In the rest of Africa, the language of the colonial power—French, Portuguese, Italian, Spanish, German, and English, depending on the area—made only limited inroads in the native population. Everywhere, it remained an elite language acquired by a small minority of generally well under 10 percent of the total, who reached secondary- or university-level education. Primary schooling was frequently in the child's mother tongue, as was much grass-roots evangelization by the Christian missionaries. Outside of North Africa and the northern Sudan, Arabic

expanded with Islam, but it failed to become a lingua franca and remained almost exclusively a limited-purpose sacred language among non-Arab Muslims. Even the fact that knowledge of a European language became a near-prerequisite for the acquisition of power and wealth in postcolonial Africa does not seem to contribute to a rapid spread of French, English, or Portuguese in Africa.

In North Africa, both French and Berber yield ground to Arabic, which is becoming the overwhelmingly dominant language from Casablanca to Cairo. Much of the French-speaking population left for France or Israel at independence. As to the Berbers, they are becoming increasingly Arabized, although many remain situationally bilingual. Most tropical African countries (except for a few small ones like Somalia, Swaziland, and Lesotho) are divided into a multiplicity of first language groups, and thus, their elites find it convenient to continue using French, Portuguese, or English as the language of administration. Indeed, elite monopoly over these former colonial languages serves to consolidate the political control of these Europeanized black mandarins. To speak of African countries as Francophone, Anglophone, or Lusophone is a hyperbole. Only a small urban elite—typically under 10 percent, often under 5 percent of the population—speaks these languages with any fluency, and that group is not expanding due to limited educational facilities. Indigenous languages hold their own quite well, since they continue to be used extensively even by the elites who are generally bilingual, and some African languages have even extended their spread well beyond their native speakers to become linguae francae. This is, for instance, the case with Hausa, Wolof, Mandingo, and Fula in West Africa, Lingala in the Zaire basin, and Swahili in East Africa, especially in Tanzania where it has become the unifying 'national' language of an ethnically very diverse country (Polomé and Hill 1980).

The decline of European colonial languages in Asia is even more rapid than in Africa. Where the colonized country had a unified language as in Vietnam, or was successful in imposing one as in Indonesia, the colonial language receded quickly after independence. The main exception is India, and even there, Hindi is slowly supplanting English as the lingua franca of northern India. Only resistance of south Indians to Hindi as a 'national' language maintains English as the lingua franca of the south Indian elite. Even in the few enclaves of Asia which remained European colonies until the late 1990s, such as Macao and Hong Kong, the native language thrives and the European ones are receding.

Representation

R. Fowler

Certain intellectual and cultural trends, and technological developments, originating in the nineteenth century, have formed a set of commonsense beliefs about the relationship between the communicative media and 'reality': the philosophy of utilitarianism; the rise of sociology; realism and naturalism in nineteenth-century fiction; the rise of newspapers (and all the 'information-gathering' services that support them) and their claim of objectivity; the development of still and moving photography, sound recording, and now ever more advanced audiovisual technologies. It is in the nature of these trends to insist that an objectively existing reality can be represented faithfully in language or images (or statistics, etc.).

This naive realism, product of a dominant empiricist and authoritarian climate, has been in this century repeatedly challenged by artistic avant-gardes: cubism, trans-sense poetry, the *nouveau roman*, etc. It has also been subjected to academic critique in different domains, including art history and the sociology of knowledge. Until recently, realism of representation has not been much questioned in linguistics, partly because of an uncritical acceptance of the communication or channel model in which language is a conduit for conveying ideas unaltered from one brain to another; partly because of the problematic nature of one area of theory, the Sapir–Whorf hypothesis (see *Sapir–Whorf Hypothesis*).

An alternative conception of representation in language is basic to critical sociolinguistics (see *Critical Sociolinguistics*). Representation is regarded as a process of construction, not as a modeling. Informally, the proposal is that, whatever 'natural' structure the world might have, our experience of it is shaped to a large degree by the social (cultural, political, etc.) and ideological relationships within which we are positioned. Language has a reciprocal, dialectical, relationship with this constructed reality. On the one hand, conceding the plausibility of 'natural kinds' such as color, shape, directionality, etc., it may be proposed that much of the semantics of a language answers to the life of its speakers: this is easy enough to demonstrate as far as lexical inventory and structure are concerned, anyway. Reciprocally, as the structure of language encodes the categories of thought by which a society manages its reality, it crystallizes them, aiding the simplification of the perceived world and facilitating the transmission of received values.

1. Interdisciplinary Sources

Berger and Luckmann's central thesis is indicated in the title of their book, *The Social Construction of Reality* (1976). Reality as we perceive it and conceive of it is relative to specific cultures, specific kinds of social organizations. It is a product of social interactions among individuals, and of institutional structures and relationships. The structure of the socially constructed world we experience is affirmed when we communicate with one another, and Berger and Luckmann point out that 'conversation' has a particularly significant role in reality maintenance.

Because conversation is casual and uncritical, the ordinary terms which represent our commonsense beliefs can be mentioned without emphasis or enquiry—contrast the language of the classroom or of the law.

A parallel set of ideas, which have been most influential in linguists' formulation of the theory of representation, is found in the work of Michel Foucault (see *Foucault, Michel*). Central to Foucault's contribution is the idea of 'discourse' (see *Discourse*) a system of prohibitions and conventions, culturally originating, about what can be spoken about and how (cf. register as 'range of semantic potential' in Halliday 1978; for a detailed exposition, see *Register*).

In E. H. Gombrich's treatise *Art and Illusion* (1960), representation in the visual arts is not a rendering of a subject but the construction of a way of seeing: an illusion in his striking term. Analyzing many familiar examples, he demonstrates how the deployment of the technical properties of the medium manages the illusion. That most apparently 'natural' of properties of visual representation, perspective, was a historical development. Techniques based on converging lines with attendant differences in size in representations of objects known in world-knowledge to be equivalent in size, guided viewers to sense an illusion of depth and three-dimensionality in their experience of a flat painting.

Gombrich's approach is based on an exemplary union of historical circumstances, variety and change of technical procedures, and the contribution of the viewer's internalized knowledge. The latter dimension of his theory accords well with 'schematic' approaches to language comprehension in psycholinguistics: people understand language in terms of schematized knowledge that they project on to texts (see de Beaugrande and Dressler 1981: chap. 5, Garnham 1985: chap. 7, Johnson-Laird 1983).

The Sapir–Whorf hypothesis contains two claims (see also *Sapir–Whorf Hypothesis*; *Sapir, Edward*; *Whorf, Benjamin Lee*). 'Linguistic relativity' argues (contrasting native American and European languages) that the structures of languages differ in fundamental ways, particularly as the semantics and syntax represent spatial and temporal aspects of experience, and material processes. 'Linguistic determinism' suggests that speakers are constrained to perceive and think along the lines afforded by the structure of their language. As far as relativity is concerned, 'difference of structure' needs defining very carefully. 'Determinism' in the form implied by Whorf is untestable. However, there is some psycholinguistic research to the effect that the simplicity with which a concept is coded has an influence on the accessibility and the memorability of that concept (Carroll 1964, Clark and Clark 1977); coding varies from language to language, even for the so-called 'natural categories.'

The cross-linguistic comparisons which Whorf makes are not central to the linguistic theory of representation, and rather serve to muddy the water; more important is that an individual language provides alternative ways of coding a concept or an event. Alternative wordings or phrasings segment or package experience in ideologically distinct ways.

2. Representation in Functional–systemic Linguistics

Halliday's *Introduction to Functional Grammar* (1994) has a section 'Clause as Representation' which begins in a Whorfian manner. He asks the reader to imagine a natural scene, birds flying overhead: 'perceptually the phenomenon is all of a piece; but when we talk about it we analyze it as a semantic configuration'; and there are different ways of analysis—'birds are flying in the sky' or 'it's winging' (1994: 108). The implication is that alternative linguistic expressions encode differently structured experiences. Halliday locates representational alternativity within what he calls the 'ideational' function of language: 'it is through this function that the speaker or writer embodies in language his experience of the phenomena of the real world' (1971: 332). This representational function is served by systems of linguistic options of which the most important are lexis and transitivity. Lexis (vocabulary) is taxonomically organized: systems of words categorize the objects, qualities, and events recognized by the culture into sets of hierarchical relations, providing an organized mapping of experience; the structure is value-laden—'girl' is opposed to both 'boy' and 'man'; alternatives are richly available which signify different orientations—'money,' 'capital,' 'investment,' 'loot,' 'bread,' etc. In Halliday's terms, transitivity refers to the semantic structure of the clause: who does what to whom, who experiences what, and so on (1994: chap. 5); choices made in the transitivity system are fundamental to the way in which a text offers a perspective on an event.

Halliday's most memorable demonstration (1971) of the construction of a mode of experiencing through linguistic structure concerns a fictional text—William Golding's *The Inheritors*. This is a classic study of the way in which a fictional world is constructed, with consistent and foregrounded transitivity choices defamiliarizing experience for the reader by staging an illusion of the causally restricted cognitive world of 'Neanderthal Man.' This study makes it clear how fundamentally important the linguistic theory of representation is for our understanding of the way in which language is structured to create fictional worlds and 'mind-styles,' but here we are talking about the deliberate textual strategies of a professional novelist.

The crucial point about representation is that the linguistic construction of reality is not limited to

605

deliberate fictional technique: the principle pervades language. Recall Berger and Luckmann on conversation, the casual way in which we share and maintain our society's categorization of experience by uncritically mentioning the terms in which it is divided up and sorted. The same ideological working is found in familiar modes of public discourse: the news media (Fowler 1991), rules and regulations, official documents, interviews, etc., have all been shown to encode commitments to specific systems of values, ways of representing the world (Fowler et al. 1979). These values, which are conveyed in recognizably distinct genres or registers of language (advertisement for women, right-wing newspaper editorial, letter from bank, etc.), are institutionally grounded: they are representations of the world in terms appropriate to the social and economic needs of the organizations that utter them. Representation, which is always from some specific point of view, can be seen not just as an innocent process but a social practice, conscious or not.

Semilingualism

J. Cummins

Considerable debate has focused on the question of whether some students from linguistic minority backgrounds can be characterized as 'semilingual' (sometimes termed 'doubly semilingual'), a condition that implies inadequate development of both first and second languages (L1 and L2). A related question concerns the extent to which such linguistic and/or cognitive deficits may be regarded as causal factors in explaining the poor academic performance of some minority students (Cummins and Swain 1983, Edelsky et al. 1983, Hansegard 1972, Kalantzis et al. 1989, Martin-Jones and Romaine 1986, Paulston 1982, Skutnabb-Kangas 1984, Stroud 1978). In many respects the controversy parallels the issue of whether working-class children are characterized by language deficits that contribute to their difficulties in schools (Bernstein 1971, Labov 1970).

Hansegard (1972) has provided the most elaborate description of the construct of 'double semilingualism' based on his observations among Finnish and Saami communities in Northern Sweden. Six characteristics are outlined by Hansegard:

(a) size of the repertoire of words, phrases, etc., understood or actively available in speech;

(b) correctness with respect to syntactic, phonemic, and discoursal aspects of language use;

(c) degree of automatism in use of the language;

(d) ability to create or neologize in the language;

(e) mastery of the cognitive, emotive, and volitional function of language;

(f) degree of richness in the semantic networks available to the individual through the language.

Edelsky et al. (1983) characterize this description of the construct as 'a confused grab-bag of prescriptive and descriptive components' and argue that to attribute minority students' academic difficulties to 'semilingualism' even as one link in a causal chain constitutes a deficit theory that 'blames the victim.' Paulston (1982) similarly argues that there is no empirical evidence for the construct and deplores its use (primarily by Skutnabb-Kangas) in the Swedish debate as an argument for Finnish home-language classes. Martin-Jones and Romaine (1986) also dispute the existence of 'semilingualism.' They attribute apparent inadequacies of linguistic competence among bilinguals to the normal processes of language contact and language shift.

Skutnabb-Kangas (1984), in response to criticism, makes the point that most of the studies that claim

not to have found evidence for inadequate command of two languages have focused on *syntax*, whereas many of those that support the construct have focused on range of vocabulary. She furthermore argues that semilingualism cannot be regarded as a deficiency inherent in the individual but should be treated as one result of the societal and educational discrimination to which minority groups are subjected. In other words, it is a political as much as an educational construct. Semilingualism can be avoided when minority children receive intensive L1 instruction through 'language shelter' (i.e., L1 immersion) programs.

Several authors have adopted an intermediate position with respect to this debate. McLaughlin for example, suggests that:

> Semilingualism may be a useful way of describing those cases where, through extreme social deprivation, bilingual children do not learn to function well in either language. At issue here, however, is whether it is a useful concept when talking about bilingual children in general. If the concept of semilingualism is defined as meaning that bilingual children do not perform as well as native speakers in either language, then there is some agreement that in fact this may be the case at certain points in the development of their languages.
>
> (McLaughlin 1985: 33)

Kalantzis et al. similarly point to the situation 'in which the home language is not continued with growing sophistication past entry to formal schooling either at home or at school, and in which the initial experience of formal schooling does not adequately prepare students for proficiency in their second language' (1989: 30). They suggest that the consequence of this situation can be what they have termed a 'cognitive void' (or what Hansegard has termed 'semilingualism') in which 'children's ability to express themselves and manipulate the world around them through language is hampered' (1989: 31).

Appel and Muysken (1986) make the point that the bilingual's verbal repertoire can be viewed as different and not deficient, even though at some point in their development they may know less of each of their languages than monolingual children. For example, bilinguals' code-switching abilities give them the opportunity to convey messages in subtle and sophisticated ways not available to monolinguals. Appel and Muysken also point out that comparisons with monolinguals may not be justified since bilinguals use their two languages in different domains and for different purposes. In other words, from a sociolinguistic perspective, the two languages of the bilingual can be viewed as one linguistic repertoire that is adequate in a wide variety of situations.

The issues in this debate appear to be less complex than might be indicated by the heated controversy that surrounds the use of the term. In the first place, virtually all theorists on both sides of this issue agree that the major causal factors in minority students' underachievement are sociopolitical in nature; specifically, the pattern of dominant–subordinated group relations in the wider society and the interactional manifestations of these relations in the school context. Second, if one admits that variations in language and literacy abilities exist among monolingual populations, then there is no reason to deny the existence of such variations among bilingual populations in their two languages. It is clear that there are major individual differences in literacy skills and in certain aspects of oral language skills among the general population in their L1s (or first languages). Not everybody is capable of reading and writing at the same level nor does everybody have identical oral repertoires (e.g., oratorical skills). In the same way, bilingual children and adults vary in their degree of mastery of different aspects of their two languages. Even Edelsky et al., admit that 'semilingualism might mean something more substantial (e.g., an inability to use language in its ideational or representational function...)' (1983: 11).

If it is allowed that variation exists, then it appears that certain bilinguals will have relatively low levels of literacy in both their L1 and L2 (or second language), while others will have relatively high levels of literacy in both languages. Certainly some minority children born in the host country who do not receive sufficient L1 instruction at school develop L1 oral and literacy skills only to a very limited extent (Wong Fillmore 1990). These children will also vary in the degree of formal L2 academic skills that they develop at school. The extent of mastery of these formal language skills is directly linked to future educational and economic opportunities. As Kalantzis et al. (1989: 31) point out, 'in the modern world, formal language skills of speaking, reading and writing are the means to certain sorts of futures and power.' They suggest that all children should have the opportunity to develop mastery of these formal language skills and academic researchers 'who have mastered the pinnacle of mainstream language' should not view as unproblematic the fact that a disproportionate number of minority students fail to realize the full range of options in their two languages.

In short, the issue does not seem to revolve around the existence of variation in language and literacy skills among bilingual (and monolingual) populations. The issue is rather whether it is appropriate or theoretically useful to label some of these bilingual children 'semilingual' or 'doubly semilingual' or 'deficient' as a means of characterizing their relatively limited repertoires in certain aspects of their two languages.

There appear to be compelling scientific and sociopolitical reasons to avoid using such labels. First, as

the debate clearly shows, there has been no precise linguistic or cognitive operationalization of the term 'semilingualism.' In other words, there is no scientific rationale for choosing one arbitrary cut-off point over another as the level below which it is appropriate to label an individual 'semilingual.' Thus, the term has no explanatory or predictive value but is rather a restatement of the vague notion of 'limited proficiency in two languages.' At a sociopolitical level the term has assumed pejorative connotations and may be misinterpreted as suggesting that linguistic deficits are a primary cause of minority students' academic difficulties, despite denials to the contrary. Furthermore, the futile debates to which use of the term has given rise, suggest that its continued use is counter-productive.

There appears to be little justification for continued use of the term 'semilingualism' in that it has no theoretical value and confuses rather than clarifies the issues. However, those who claim that 'semilingualism does not exist,' appear to be endorsing the untenable positions that (a) variation in educationally-relevant aspects of language does not exist, and that (b) there are no bilinguals whose formal language skills are developed only to a relatively limited level in both L1 and L2. Just as there are monolinguals whose formal language skills are developed only to a limited degree, so too there are bilinguals whose formal language skills are developed only to a limited degree.

Stereotype and Social Attitudes

M. L. Apte

'Stereotype' is an important concept in the discussion of the social reality of any culturally bound aggregate of human population. The concept was given a definitive formulation by the American journalist Walter Lippmann in 1922. It has been controversial however, and has been much discussed in the social science literature primarily in the context of contact and interaction by various ethnic groups within and across modern nation-states. It is also significant in the exploration, discussion, and analysis of ethnic humor, especially ethnic jokes.

1. Conceptual Formulation of Stereotype

Lippmann (1922) defined stereotype as a mental picture formulated by human beings to describe the world beyond their reach. In his view, stereotypes are at least partially culturally determined. He emphasized however, that their contents are factually incorrect and that they are the products of a faulty reasoning process. He felt that stereotypes are difficult to get rid of, and they persist even when a group is exposed to education and has first-hand experience concerning the phenomenon or human groups about whom stereotypes are held.

A stereotype is now considered to be an over-generalization and an uninformed one. It is also intertwined with strong positive or negative attitudes. It is inevitable that cultural knowledge includes not only information about one's own actions and behavior, institutions, traditions, customs, and artifacts, but also about other human groups and the environment. The concept of stereotype primarily focuses on the knowledge of other sociocultural groups, especially factual or putative racial and

ethnic characteristics and their behavior. In order for one group to hold a stereotype of another, the former does not have to be in direct contact with the latter.

In the 1930s many studies were conducted by psychologists to test the validity of stereotypes. The most well-known among these is that of Katz and Braly (1933). It was based on the experiment conducted at Princeton university in which 100 students were asked to list the traits they considered characteristic of 10 ethnic groups. They were to select the traits from a predetermined list given to them. Many similar studies were conducted during the 1950s and the 1960s. Yet none of them was conclusive regarding the correlation between stereotypes and empirical reality.

To what extent, if at all, prejudice and other negative attitudes are associated with stereotypes is a controversial issue that has been much discussed. Allport (1958) is of the opinion that prejudice is generally an essential aspect of stereotypes, especially negative ones. It has also been argued that ethnocentrism, the natural tendency of each and every sociocultural group to hold its own culture to be superior to all the others is a major cause for developing negative stereotypes. Behavior, customs of dressing, eating habits, speech patterns, sexual practices, and other aspects of culture that substantially differ from those of one's own are perceived as 'primitive' and 'repugnant.' Such conclusions and generalizations do not have to develop from first-hand information, but rather from hearsay evidence or from superficial observation of even a single member of another group.

Although stereotypes are generally considered uninformed opinions it has been argued that they are not totally false, but that there is some degree of truth in them. This has been known as the 'kernel of truth' hypothesis in the literature on stereotypes (Brown 1965: 172). However, one study (La Pierre 1936), much quoted in the literature, showed that stereotypes persist in spite of their contradiction or falsehood in the face of 'objective reality' or 'empirical truth.'

Stereotypes of groups based on such factors as occupation, sex, age, social, or economic status also exist in addition to those based on ethnic and/or national identity. In the culture of the USA, as in many others, women are stereotyped as bad drivers, excessively talkative, and easily given to emotional display. In many societies lawyers are stereotyped as unscrupulous, politicians as corrupt, and villagers as stupid and ignorant. As for the national stereotypes, the Scots are perceived as miserly, the Germans as excessively rigid, the English as stiff, the French as expert in love-making and cooking, the Jews as shrewd and good in business, and American Indians as inscrutable.

Folklore in most societies abounds with oral narratives based on stereotypes of other societies and nation-states. These images in folklore are due to what Jansen (1959) has called the esoteric–exoteric factor in folklore. He describes it thus: 'The esoteric applies to what one group thinks of itself and what it supposes others think of it. The exoteric is what one group thinks of another and what it thinks that other group thinks it thinks' (Jansen 1959: 206). Popular jokes based on national and other stereotypes constitute a major genre of such folklore (Davies 1990, Dundes 1971, 1975, 1987).

2. Stereotypes and Intergroup Interaction

In multi-ethnic nation-states, diverse cultural and linguistic groups and their members come in contact with each other and are forced to interact, even if on a limited basis. Stereotypes hinder such interaction and social discourse because they create misunderstanding. Dominant and/or majority groups tend to use stereotypes to justify their unjust treatment of powerless and/or minority groups. Interestingly, some dominated and/or minority group tend to accept their stereotypic image as created by others, but with a positive rather than a negative attitude. Sociocultural change and major historical events may affect the existing stereotypes in a society.

Symbolic Power and Language
C. B. Vigouroux

Just as the military strategist Clausewitz saw war as an extended form of politics, Pierre Bourdieu sees language not only as a self-contained system, but also as the political instrument of power struggles, a kind of 'battlefield.' By identifying language as an area in which power relations are created and exercised, Bourdieu (1977: xx) shows that the act of speaking does not merely involve exchanging information: 'language is not only an instrument of communication or knowledge but an instrument of power.' An important aspect of the Bourdieusian approach is the linking of Marxist and Weberian thought. Whereas Marxist society is based on the dominant/dominated dichotomy, Weber sees social reality as a combination of relations of meaning which give place to a symbolic dimension: power can also be administered symbolically.

Language for Bourdieu is considered within a wider attempt to deconstruct the mechanisms of domination, which form the basis of social relations. Language is everywhere, embracing all levels of society, and for Bourdieu it is an ideal means of getting to the bottom of this domination: while a physicist will talk about physics, a football fan about football, a computer programmer about computers, the common factor between them all is the use of language. Just as the psychoanalyst uses language to listen to that which his/her patient suppresses, Bourdieu the sociologist uses language to listen to that which society conceals.

1. The Economics of Linguistic Exchanges

Bourdieu seeks to construct a 'general theory of the economy of practice.' In the same way as we have a monetary economy, we also have a linguistic economy: language is exchanged as a product, which, within an *economy of linguistic exchanges*, is given a *price* and a certain *value*. Thus Bourdieu talks of linguistic, cultural, or political capital, etc. Linguistic capital acquires its value within *linguistic markets*, which include, for example, the education system, the labor market, the arts, government, etc. These act as authorities, which legitimize language, use and govern *price formation*. For Bourdieu communication does not only involve the giving and receiving of messages, but it also implies economic or symbolic value. While speaking like a politician will be appreciated within the appropriate settings, at the same time it may be devalued within other settings (e.g., among certain younger age groups) where it will be considered 'wrong currency.' While a word like *fuck*, for example, is not permitted in school, it may be taken up elsewhere by certain groups of people

and used as an identity marker. The linguistic market therefore exists because language, like any other product, can be subject to transactions.

Language does not convey an individual's experiences. Rather, it is the individual's experience itself in that he/she is a historical individual, evolving within a particular social environment. Bourdieu's approach, rather than treating language as a closed system, takes the speaker along with the conditions of communication as the central aspect: 'a scientific approach to speech must take into account the conditions in which communication takes place since the expected reception conditions are bound up within the production conditions' (1977: 21). By doing this Bourdieu disputes the validity of a structuralist (i.e., Saussurean, see *Saussurean Tradition and Sociolinguistics*) approach to linguistics which attempts to explain linguistic features in terms of internal patterned organization or structure. Although Bourdieu does not deny language's autonomous nature as a *structured structure* (means of communication, language, or culture vs. discourse behavior), he goes on to add, however, that it is also a *structuring structure* (instruments for knowing and constructing the objective world) and can, therefore, become an *instrument of domination*.

2. Ideology and Legitimation

With the idea that the individual is born into a language—i.e., into an already existing system, with its phonological, syntactical, lexical, and morphological features—comes the idea of being born into a certain ideology relative to the language in question. Language is, above all, a means of apprehending the world: learning Mandarin for a European, for example, means not only learning the language system, but also learning to organize and categorize the world differently. If we take the example of a writer, writing in his/her first language, his/her particular style will reflect a certain vision of the world (see *Sapir–Whorf Hypothesis*).

An individual or an object cannot exist without a name: by giving people or things names we admit their existence. The naming of a newborn baby amounts to giving him/her a social baptism. The English philosopher Austin (1962) shows how 'saying is doing' with the speech-act example of the ship which is named by pronouncing the words 'I name this ship the *Queen Elizabeth*.' However, Bourdieu would argue that by actually naming the ship, the person demonstrates his/her legitimate right to do so; 'doing is saying.' So, while speaking implies saying something to somebody, it also amounts to telling

somebody who we are and what we stand for. Stylistic variation can be linked to the speaker's motivated communication strategy vis-à-vis his/her audience: for example, a pensioner who refers to someone as 'well cool,' not only manifests an appreciation of the person in question, but also adopts a particular stance (identifying with the young or trendy) in choosing this register. More importantly than, for example, morphology or syntax, it is the way in which the language is actually put to use which interests Bourdieu: the *mise en scène* of language gives us an insight into society's hidden structures.

Words are actualized within a given context of communication; they take on specific meanings according to the speakers involved. This implies complicity and the establishing of a tacit contract between speaker–formulator and listener–decoder alike. For Bourdieu, society can not only be split into dominant/dominated groups but it can also be divided up into 'fields' (*champs*). These consist of small spheres, which dispose of their own value systems. Within a given field, a previously dominated subject can become the dominant one. The speech of a given individual will be more or less 'legitimate' according to the particular field in which it occurs. For example, if a book reviewer who is not a literary specialist writes in a newspaper that a book is 'interesting,' his/her judgments will have a particular value. However, within another field, such as that of the university, these may be played down.

3. Symbolic Power

Power is rarely exercised overtly as a physical force for any length of time. Rather, it takes on a symbolic form. In order for *symbolic power* to be exercised it must first of all be *interiorized*, i.e., acknowledged as something natural, which goes without saying by those who are subjected to it. In the case of language prescription, where the norm or 'approved correctness' in speech is prescribed by the education system, for example, this process does not only involve the simple imposition of a given linguistic variety, but it also implies speakers' interiorization of the idea that their variety is of low prestige. And, while those concerned may get the impression that this takes place at a purely linguistic level, it is in actual fact another kind of domination. So, it is not only by *recognizing* the means of domination, but also by '*misrecognizing*' its ends, that symbolic power is transformed into *symbolic violence*. The nature of *symbolic violence* for Bourdieu is, then, twofold, being based on the recognition–misrecognition pair. This is part of a key concept in Bourdieusian sociology, i.e., *habitus*, which concerns the ways in which social structures are impressed upon our minds and bodies (*corporal hexis*) becoming *durable* and *transposable dispositions* (*Le sens pratique*, 1984). A

further example can be seen in the process of colonization by European countries. This not only concerned the colonization of space, but also extended to the colonization of the mind. The language of the colonizer, with all it conveys (imposition of the dominant science, history, technology, and ideology), contributed to the colonized subject's interiorization of the master as a master to the extent that the former came to discredit his/her own language(s), history, science, and technology.

Given that language not only forms part of our environment, but also serves to construct our environment, totalitarian regimes have always sought to control language in order to subdue society or to control society in order to subdue language. The French Revolution provides us with an example of the reworking of time via the implementation of new ways of naming things with the setting up of a calendar with new names for the months of the year (*vendémiaire, brumaire, pluviôse*). The many different forms of domination operate most discretely and also most violently in language. As Baudelaire points out, all the devil's trickery lies in making us believe that he does not exist. Thus language, of all forms of power, is the one which can have the greatest effect. It is the fact that language is a symbolic form of power that an individual, group, or institution can use it as a weapon to exercise symbolic violence.

The Linguistic Marketplace
I. Gogolin

The idea of the existence and functioning of a linguistic marketplace was originally created by the French sociologist Pierre Bourdieu; it is described in detail in Bourdieu's 1991 work *Language and Symbolic Power*.

Throughout his works, Bourdieu examines the question of how power relations in a society emerge and stay relatively stable, and how they are traditionalized although certain changes take place. A key concept for the explanation of these processes is that of *habitus* (see *Linguistic Habitus*). According to Bourdieu, a habitus is the set of dispositions, which incline the manner of action and reaction of the individual. A habitus generates durable practices and attitudes in people; it pilots their perception of normality. As a habitus is acquired under certain social conditions of an individual's existence, members of a social class and people of similar backgrounds tend to relatively homogeneous habitus.

The concept of habitus allows the principles which underlie the practices and perceptions of the individual to be described. Complementary to these, Bourdieu offers the concept of *field* or—as a largely synonymous metaphor—*market* for a description of the social contexts within which individuals act. Though these terms are borrowed from economics, the analysis based on these terms goes far beyond the assumption of simple economic transaction in human action.

A field or market may be seen as a structured space of positions, which are determined and interrelated by the distribution of different kinds of *capitals*. These are special resources, which an individual is equipped with—namely by heritage, but possibly also by one's own achievements. Bourdieu proposes that there are different forms of capitals: *economic capital* (money, stocks, shares, property, etc.), *cultural capital* (skills and knowledge, cultural acquisitions, and other qualifications, etc.), *social capital* (human relations, contacts, and connections, etc.). When these capitals are officially accepted as the worth of an individual, they function as *symbolic capital*: the accumulated honor of a person (see Bourdieu 1998). The capitals can be converted into the other; for example, social capital as well as cultural capital can be exchanged for reputable jobs.

The actors in a field or market usually have a tendency to either preserve their position or struggle for a better one, depending on where they are located. In these struggles—Bourdieu also refers to them as *games*—all participants share a common set of rules or unquestioned beliefs, to which belong the interpretations of the values and operation of capitals. But participation in the struggle or game is not to be understood as the mere result of constant conscious calculation. Individual practices are more likely a result of habitus: predisposed ways of action, deep-seated, unconscious beliefs and presuppositions. Apart from strategic activities, the ways of accumulation of capital and of investing capital are clearly influenced by habitus.

Linguistic utterances are forms of practice, which can be understood as the product of the relation between linguistic habitus and linguistic market (Thompson 1991: 17). The linguistic habitus of a person—as part of the habitus as such—governs his or her ways of language behavior as well as the judgment about the values of languages, forms of speech, or linguistic expressions. Articulatory styles differ according to class and region, and can also differ according to sex. The different styles are endowed with different values, which are related to the distribution of other forms of capital. The symbolic value, which is connected with a language or an articulatory style, is handed down historically. In many societies, especially the classical European nation states, the best recognized language variations, i.e., those which receive unquestioned respect by everybody, at any given time and which are connected to the highest amount of symbolic power, are the official national languages in their standard form. Nevertheless, the values of different articulatory styles differ in particular contexts or markets. For example, in a youth group, a conversation in standard language will probably not be adequate, and in a rural area the local dialect may be the appropriate medium for an address at an official celebration.

612

Linguistic competence in this approach does not refer to a uniform notion of formal correctness or to the technical command of a language, but refers to the ability of using language or language variants in a manner that secures a 'profit of distinction.' The social and symbolic power of languages or language use does not derive from language as such, but from the settings—the particular contexts or markets—in which communication takes place. The reproduction of symbolic power related to languages or to language use functions by virtue of every speaker's assessment of market conditions. Speakers modify their language use according to their anticipation of its reception and acknowledgment. If they struggle for a better position in a society, they will probably try to reproduce the expressions and styles, which they know as valued more highly than others. This is why people from lower classes tend to give up their modes of expression when they aspire to a better position in society. On the other hand, people from upper class backgrounds usually respond with relative ease to the demands of different language situations. Their linguistic habitus enables them to handle diversity, and this may include the use of a regional dialect or social variant in specific situations. The socially constructed dispositions of the linguistic habitus imply a certain propensity to express oneself in an appropriate manner and a capacity to speak. This capacity involves the linguistic capacity to generate an infinite number of discourses as the social capacity to use this competency adequately in specific situations. The structures of the linguistic market impose a system of specific sanctions and censorships on speakers (Bourdieu 1991: 37).

The concept of a linguistic market was developed from a (Western) European perspective and describes the part of language in the process of social distinction in capitalistic societies. But it can also be useful as a frame of reference for the study of power relations in other areas of the world, namely colonial and post-colonial countries (cf. Goke-Pariola 1993).

Language Planning, Policy, Practice

Academies: Dictionaries and Standards
L. C. Mugglestone

National academies, influential and often authoritarian bodies devoted to the maintenance and regulation of individual languages, first appeared in Europe in the sixteenth century, though the Hebrew Language Academy was, for example, founded as late as 1953. The production of a dictionary was often given as a major objective in the foundation of such institutions, particularly since a dictionary was seen as one of the main ways by which the issues of language maintenance could be realized. As a result, academy dictionaries frequently reflect the ideals of conscious linguistic standardization which came to prevail in the Renaissance as well as afterwards.

1. The Accademia della Crusca and the First Academy Dictionary

The Italian Accademia della Crusca was, in 1584, the first such academy to be established, its guiding principles being based in the intended regulation of the language, and the production of a dictionary being given as one of its main aims. Like the Académie Française which was to follow in 1635, or the attempts to found a similar body in England around the end of the seventeenth century, the Crusca was in many ways explicitly preoccupied by the notion of linguistic authority, and by the need for a national standard of linguistic usage. Its dictionary, the *Vocabulario degli accademici della Crusca*, published in Venice in 1612, naturally embodies these aims; the words it records are those supported by the written authority of great works, rather than by current usage, and lexical innovation is tolerated only where felt to be unavoidable.

Such principles of lexical selection were employed under the joint banners of patriotism and purism; the intention was to remedy the perceived 'degeneration' since the linguistic 'Golden Age' of the fourteenth century, and also to reflect a new concept of the vernacular, as a language in its own right, rather than as a debased form of Latin. The linguistic concerns are therefore normative and conservative, and the *Vocabulario* was felt to be the preserve only of the best usage, and more specifically, the best literary usage.

2. The French Academy

The role of academy dictionary as linguistic exemplar was also adopted within the methodological principles of the Académie Française, one of its founding tenets being 'to labor with all possible diligence to give definite rules to our language, and to render it pure.' Its own dictionary, published in 1640, is shaped by these issues of linguistic propriety; recording only those usages felt to be redolent of 'le bel usage,' it is above all, like the *Vocabulario*, a dictionary of the written language, literary authority sanctioning the introduction of words where current usage could not, with the result that archaic words are often admitted to the exclusion of newer ones. As the Preface to the seventh edition of 1877 records, 'A word is not dead because we no longer employ it, if it lives on in the works of a Molière.' Many of the original authoritarian principles were maintained in successive editions; the Preface to the second edition of 1718, for example, makes explicit its decision to exclude words such as *fichu, ratafia, bizarre*, and *sabler*, whilst that of 1877 notes that words which seemed ill-composed, or contrary to 'the genius of the language' have likewise not been admitted. The academy dictionary in this way becomes not a dictionary of the language in itself, but instead a dictionary of the words felt to merit existence in that language.

3. Proposals for an English Academy

Such standardizing ideals within the preserve of lexicography in turn exerted their influence upon England. Daniel Defoe in his *Essay upon Projects* (1697) urged the creation of a legislative body in linguistic matters which would 'polish and refine the English tongue, and advance the so much neglected faculty of correct language . . . to purge it from all the irregular additions that ignorance and affectation have produced.' Such a plan, however, never came to fruition, and Dr Johnson's own dictionary (1755),

praised, for example, by David Garrick as the English equivalent of the *Dictionnaire* of the Académie Française, is tempered by a sense that the dicta of academies cannot control lexical change, nor fix its norms of propriety. As he notes in his own Preface in 1755

> With this hope, however, academies have been instituted, to guard the avenues of their language, to retain fugitives, and to repulse intruders; but their vigilance and activity have hitherto been in vain; ... to enchain syllables, and to lash the wind, are equally the undertakings of pride, unwilling to measure its desires by its strength.

4. The Twentieth-century Context

Though academies attempted therefore to prescribe lexical norms, and to codify the patterns of the best usage in terms of literary authority, the principles of lexical exclusion and selectivity which they advocated were not followed in the actual language itself, where usage is the only guide to lexical existence, rather than the arbitrary norms of official institutions. Recent lexicographical developments, even within the sphere of academy dictionaries, have in a number of ways come to recognize this fact, though the dicta of the Académie Française can still be marked by a certain lexical xenophobia, as well as by a qualitative bias in the words it records: the Preface to the *Dictionnaire* of 1935, for example, noted that new words have indeed been listed, but only those which have been judged of sufficient dignity to merit admittance.

Artificial Languages

A. Large

An artificial language has a vocabulary and a syntax, a writing system, and normally also a phonology. It is used to communicate between human beings although some artificial languages such as programming and command languages are used by humans to issue instructions to machines. Unlike a natural language, however, it has one or more creators who were responsible for its design. Artificial languages are related to other kinds of linguistic creations such as cryptographs and shorthand systems. Although some speakers have learned an artificial language from their parents at the hearth, in most cases such languages are learned through study. It is worth adding that many users of artificial languages do not themselves care for this terminology. They believe that artificial implies such negative characteristics as lifeless, second-rate, or unnatural, and prefer the terms 'constructed language' or 'planned language.'

At a conservative estimate some 500 artificial languages have been created since the seventeenth century and new ones regularly appear. Few have attained wide-spread use, however. Esperanto, now more than a century old, must be acknowledged the most successful when measured by numbers of active users, geographical distribution, and publications. Precise and reliable figures for artificial language users are difficult to come by. This is partly because a clear definition of user is difficult to formulate for languages which are normally learned as a foreign language rather than as a mother tongue. Users can range from those who are fluent (itself by no means unambiguous) in speech and writing to mere purchasers of language primers. Quantification is also problematical in a partizan field where statistics have a propaganda value and estimates vary dramatically between supporters and detractors of any particular language.

1. Categorization

Artificial languages can be categorized as *a priori* or *a posteriori*. An *a priori* language is composed entirely of invented elements not found in any natural language, and is usually based on a logical classification of ideas. Relationships between things in the real world can be expressed taxonomically by the language itself, the object being to remove ambiguity and create, as Leibniz put it, an 'instrument of reason.' In practice, however, this tends to make the language more difficult to learn and use. Ro is an example of an early twentieth-century *a priori* language. Knowledge is divided into 25 main classes, each with further levels of subdivision. Related

concepts are indicated by alphabetically similar words so that *bod* is universe with subclass related terms such as *bodam, bodas,* and *bodar* for moon, sun, and star, respectively.

An *a posteriori* language is based on elements of grammar, vocabulary, and syntax drawn from one or more natural languages. This more pragmatic approach is usually motivated by a desire to design a workable auxiliary language which can be easily learned and used by everyone. Natural languages, however, are replete with irregularities and inconsistencies. An *a posteriori* language like Occidental attempts to remain close in form to its natural language parents (chiefly the Romance languages) and is therefore relatively easy to read, at least, for the educated elite of western Europe. Unfortunately this naturalistic element can only be purchased at the expense of numerous irregularities in Occidental. *A posteriori* languages like Esperanto and its offshoot, Ido, are much more regular but thereby less closely identifiable with the European languages on which they were based.

Modified natural languages are closely related to naturalistic *a posteriori* languages, having many similarities in approach and objective. In practice the distinction between a naturalistic artificial language like *Latino sine flexione* and a modified natural language such as Basic English is relatively minor. The objective here is to simplify acquisition and use of a natural language by eliminating its most awkward features—usually irregularities of grammar, spelling, and pronunciation—coupled with a reduction in vocabulary. Basic English, for example, functions with a vocabulary pared down to fewer than 1000 words, achieved by eliminating synonyms and by building complex terms from their simple components. The drastically-reduced vocabulary certainly facilitates reading but requires considerable linguistic ingenuity and skill on the part of the writer.

2. History

Although interest in language creation goes back much further, it was in seventeenth-century Europe that the idea of constructing languages first became a serious proposition. Many different motives have attracted people to this task. An intrinsic interest in language itself is essential but rarely sufficient of itself, and few language constructors have been professional linguists. The early schemes of the seventeenth century were prompted by philosophical, religious, scientific, and commercial considerations. The decline of Latin as an international language prompted a quest for a new vehicle to communicate the growing output of scientific publications, while traders and missionaries needed a language which could be taught to the natives of the Far East and Americas so as better to trade goods and save souls. Of even more importance, however, was the desire to construct rational, philosophical languages which would avoid the confusion and discord created by ambiguous, ill-structured natural languages. It was this goal which attracted the likes of Descartes, Leibniz, and Wilkins to their linguistic endeavor.

Of the many universal language projects contemplated or actually constructed at that time, the clergyman John Wilkins's *An Essay Towards a Real Character and a Philosophical Language* (1668) is the most impressive and most fully developed. Relying largely upon the Aristotelian distinction between genus and difference Wilkins attempted to allocate 'all things and notions' to 40 classes so as to group related concepts in some kind of meaningful order. He then provided grammatical rules by which simple concepts could be assembled into complex ideas. This *a priori* language played a role in the standardization of scientific nomenclature and inspired Roget during the compilation of his *Thesaurus*, but Wilkins did not succeed in establishing a universal language.

The construction of philosophical languages held less attraction in the eighteenth century and enthusiasm for universal language projects flagged without quite disappearing. Its reappearance in the second half of the nineteenth century was prompted not by the desire to create a philosophical language but by the perceived need for a practical, ethnically neutral language for international communication. Growing cross-border contacts at the personal, institutional, and governmental levels highlighted the barrier caused by language diversity and emphasized the advantages to be gained from the adoption of an international auxiliary language. Such practical considerations were further buttressed by idealistic motivations. For example, the German priest, Schleyer, envisaged his language, Volapük, as contributing towards universal peace, while the Jewish oculist and creator of Esperanto, Zamenhof, was haunted by the memory of ethnic conflicts in his native Poland to which he believed linguistic differences had contributed. More recently the authors of another language wrote that 'Glosa is not an end in itself, but a means of helping to rid the world of poverty and ignorance.'

This more practical concern with the growing need for an international auxiliary language has reduced the numbers of a priori schemes although they do still appear from time to time. Attention has been increasingly devoted to *a posteriori* languages, an early example of which was sketched by a Frenchman, Faiguet, in 1765. Volapük, which drew its vocabulary from the heavily modified roots of various European languages, was the first artificial language to win widespread popular support. First published in 1880, Volapük initially registered considerable successes but dissension among its supporters soon tore the movement apart. The language soon to be called Esperanto (after the pseudonym of

its creator, Doktoro Esperanto—'one who hopes') was published in a Russian edition a few years later in 1887. Despite setbacks and schisms Esperanto has experienced greater success, surviving as an active and organized movement for more than a century.

3. Characteristics

Although artificial languages are linguistically diverse, a number of general characteristics have assumed prominence. Ease of acquisition is a major criterion for any language which is to seek mass support. *A posteriori* languages attempt to facilitate learning by incorporating syntactic and morphological features found in natural languages. *A priori* languages normally look much less familiar and their difficulty to acquisition is a major argument directed against them. Yet even here their creators frequently claim that mastery can be assured with little effort. John Wilkins, for example, claimed that more of his Real Character could be learned in one month than in 40 months' study of Latin.

Precision is a second sought characteristic. In this case the language is intended to provide an unambiguous and logical medium of communication in contrast to natural languages which, it is asserted, lack clarity and consistency. *A priori* seventeenth-century schemes in particular pursued this goal. Their classifications of concepts, however, mirrored their creators' perception of knowledge and have proven neither universal nor eternal. Wilkins's Real Character, for example, is based upon seventeenth-century reality, leading him to decisions such as the classification of the whale as a fish rather than a mammal.

In most cases artificial languages have been intended for all kinds of communication and must therefore cope with the syntactic and lexical demands of numerous specialized subject domains as well as the everyday needs of their speakers. Furthermore, they must accommodate new words and constructions if they are to evolve in the way of natural languages. The supporters of Esperanto, for example, stress its receptivity to new words.

How successfully have artificial languages met these goals? The philosophical *a priori* languages have too often been difficult to memorize and use, inhospitable to new concepts and rational only to those who agree with their designer's identification and classification of concepts. *A posteriori* languages may be easier to learn, but such ease is dependent upon the learner's familiarity with the natural language or languages on which they are based. The internationalism of artificial languages primarily based upon languages in the Indo-European group, for example, might be questioned. Linguistic evolution tends to be more problematic for artificial than natural languages. The fact that the language is designed according to a blueprint can lend force to conservatism; at the same time linguistic stability can be threatened by proposals for reform which are seldom in short supply in movements whose *raison d'etre* is language. Disputes over the use of circumflexed letters in Esperanto orthography, for example, have been frequent and bitter. The history of the artificial language movement all too often has been one of acrimonious dispute, sectarianism, and fission: creators and supporters of artificial languages are ill-equipped to compromise on such matters as grammar or lexicography.

4. The Future

Artificial languages may not be so rational, expressive, neutral, and easy to learn as their supporters sometimes assert, but nevertheless they can function very effectively as a medium for written and spoken discourse. A language like Esperanto is spoken in all parts of the world, as well as possessing the linguistic richness to accept in translation the greatest literary works from a wide variety of natural languages and, indeed, to convey a sizeable body of original prose and poetry. The major problem which has always faced artificial language creators, however, is to persuade enough people to use them. An international language, to be effective, must be spoken by most if not all the world's population. Yet the total number of artificial language speakers from the seventeenth century to the present represents a mere fraction of late twentieth-century English speakers. How can people be persuaded to devote the time and energy necessary to learn even the most regular, natural, and straightforward artificial language and then to use it as a medium of communication with people who do not share their own natural language? This is the fundamental problem facing any artificial language and it is political rather than linguistic in nature.

There are two ways in which an artificial language might be adopted as a vehicle for international communication. A *de jure* decision might be taken by an international body such as the United Nations to select a language for this role. In the twentieth century a Delegation for the Adoption of an International Language was created which appointed a committee to examine scientifically the merits of a number of schemes with a view to recommending universal adoption; it only succeeded in generating a deep rift in the Esperantist movement. Once a language has been selected by the international organization it would then be necessary to ensure its acquisition by as many people as possible as quickly as possible, a task requiring international collaboration on a scale so far sadly absent from world councils.

Alternatively, an artificial language might become *de facto* the international language through sheer weight of numbers. No language movement is remotely big enough to suggest this is probable. Although a number of international organizations have toyed with the idea of adopting an artificial

language (usually Esperanto) for at least some of their activities, natural languages have not been dislodged from their stranglehold even in this most fertile ground for constructed languages. The task of winning worldwide support is formidable for an artificial language which depends for its promotion on a dispersed social group and lacks the political, economic, and cultural pressure which states can afford their natural languages.

Heritage Languages
J. Cummins

In a general sense the term *heritage languages* refers to languages other than the official or majority languages of a country. The apparent simplicity of this general definition, however, is misleading in an area as highly contested as the status of different languages in society and the social and educational rights that accrue to speakers of different languages. These struggles around status, identity, and rights are reflected in the variety of terms that have been used in Canada and other countries to refer to heritage languages. The terms *ancestral, ethnic, immigrant, international, minority, non-official, third* (after English and French), and *world* have all been used at different times and in different contexts. The term used in Quebec is *langues d'origine* (languages of origin). In other countries the term *community languages* has been used (e.g., Australia, New Zealand, the United Kingdom) and the term *mother tongue teaching* is also common.

In the Canadian context, the federal policy of support for multiculturalism within the framework of two official languages, announced in 1971, legitimated demands among ethnocultural communities that federal and provincial governments support maintenance and development of heritage languages. Advocates argued that a policy of multiculturalism was vacuous if it claimed only to support 'culture' in the absence of concern for the languages in which those cultures were embedded.

The term came into widespread use in 1977 with the establishment of the Heritage Languages Program in the province of Ontario. Funded by the provincial government for the past 25 years, this program provides support for the teaching of heritage languages for up to two-and-a-half hours per week outside of the regular five-hour school day. The term *heritage languages* was intended to acknowledge that these languages constitute important aspects of the heritage of individual children and communities and are worthy of financial support and recognition by the wider society.

In the early 1990s, the term *heritage languages* was changed to *international languages* by the provincial government, reflecting misgivings among ethnocultural communities that the notion of 'heritage' entailed connotations of learning about past traditions rather than acquiring language skills that have significance for children's overall educational and personal development. The term *international languages* was intended to communicate that, in an era of globalization, these languages were highly relevant to business and cultural exchanges and had economic as well as 'heritage' value.

Indigenous communities have resisted attempts to include their languages within the categories of 'heritage' or 'community' languages on the grounds that as 'First Nations,' the status of their languages is very different than the status of immigrant languages. Deaf communities have also grappled with the status of sign languages vis-à-vis heritage languages. For example, in Ontario, the Deaf community in the early 1990s resisted having American Sign Language (ASL) taught as just another heritage language and argued successfully for the institution of ASL as a language of instruction within a bilingual/bicultural program in the provincial schools for the Deaf. Thus, definitions of *heritage languages* remain dynamic rather than static, reflecting the contested cultural and political terrain to which the term refers.

International Languages

U. Ammon

In modern times international communication has become increasingly important. As a consequence, international languages (ILs) gain more and more practical significance. Though international communication does not necessarily depend on ILs (it can also take place via translation from one language into another), in many situations using an IL is much more convenient than translating.

The meaning of the term 'International Language' may appear clear enough at first view. A closer look, however, shows that some clarification may be useful, especially since there is no significant research tradition within which a widely accepted concept could have been established. An attempt at conceptual clarification will also open up perspectives for future research.

1. The Concept 'International Language'

'International language' is not usually found as a lemma in dictionaries of linguistic terminology. An exception is Pei (1966: 132, 128) who defines it as a language 'created or suggested for adoption for purposes of international communication.' While this definition fits a language that is *intended* as international, a more adequate way to specify the meaning of IL would be 'a language *used* for international communication.'

By definition, international communication occurs between nations, or rather, individuals belonging to different nations. The problem is that the concept of 'nation' itself is interpreted in various ways, namely at least the following two: (a) country or autonomous state; (b) nationality, defined by a common language, culture, history, and an idea of belonging together.

If possible, the definition of an IL should take into account these interpretations. A communicative act (see *Communication*) may be called 'international' if it occurs between different countries, i.e., between inhabitants or citizens of different countries, or between different nationalities, i.e., roughly speaking, between (native) speakers of different languages. If only one of the two conditions is fulfilled, the respective communicative act could be called international *only in a wider sense.*

Examples would be a communicative act either between a speaker of German and a speaker of Hungarian, both of whom are citizens of Hungary, or between a citizen of Germany and a citizen of Hungary, both of whom are speakers of German. If, however, both conditions coincide in a communicative act, it seems adequate to consider it *international in the narrower sense*, i.e., if the communicative act occurs on the one hand among (native) speakers of different languages (e.g., a speaker of German and a speaker of Hungarian) who on the other hand are citizens or inhabitants of different countries (e.g., Germany and Hungary). The more a language is used in international communication, either in the wider sense only, or also in the narrower sense, the more likely it is to be seen as international.

From the above, one sees that it would be wrong simply to separate languages into ILs vs. non-ILs (which is the approach taken by Braga 1979). Instead, the conceptual framework offered above asks for a ranking of languages, or even a measuring by intervals according to degree of internationality (Ammon 1990a: 135–8). Empirical research is necessary to determine to which extent the various languages are actually used in international communication. Only on the basis of such empirical findings will it then be justified to delimit a certain set of languages as *the most important ILs.*

2. The Most Important ILs

Trivially, the importance of a language as an IL varies with the course of time. Therefore, any characterization of a language as an IL should be specified as to the period of time for which such a characterization holds true. Thus, ancient Greek was an important IL in classical antiquity; in the late twentieth century neither classical nor modern Greek are. For reasons of space, the following considerations will be limited to ILs in the twentieth century, with only occasional glimpses back into history. For the same reason, ILs which are limited to religious functions, such as Latin for Roman Catholic Christians or Pali for Buddhists, will not be dealt with; Arabic, which is the religious language for

Muslims, is another matter, since it does not only serve religious functions.

Since it is impossible to observe all international communicative acts, empirical investigations into ILs have to rely on relatively limited samples, or even on mere indicators of international communication. The value of these indicators can often only be judged intuitively, for the same reason.

It seems clear that the number of (native) speakers of a language is of some limited significance as an indicator of its importance as an IL; however, it certainly is not too reliable a measure. Chinese has, for instance, more speakers than English, and Bengali has more than French or German; it is, however, quite obvious that English is a more important IL than Chinese, and that French or German are more important ILs than Bengali. More significant with respect to its importance as an IL is a language's *economic strength*, understood as the economic strength of its language community (i.e., the community of all its native speakers). Superior economic strength is thus one of the factors responsible for the eminent international importance of English as compared to Chinese, or of the greater international importance of French or German as compared to Bengali. Likewise, the expansion of Japanese as a foreign language can in part be explained by the considerable economic strength of its language community. A language community's economic strength makes the study of its language appear more rewarding, because that language community appears as a more promising market—to mention just one of the reasons why economic strength enhances the international importance of a language. According to one calculation (Ammon 1991: chap. 3, 4) the strength of the six economically strongest language communities around 1985 was (in terms of their GNP in billions of $US):

1. English		4271
2. Japanese		1277
3. German		1090
4. Russian		801
5. Spanish		738
6. French		669

Another significant indicator of the international importance of a language is the number of countries in which it is used, either as the native language of a considerable portion of the population, or as an official language of the country. If the number of 'its' countries is greater, the chances of a language to serve for international communication naturally increases. Around 1985, the following six languages ranked highest with respect to the number of countries in which they were official, either on a national or on a regional level (source: Banks et al. 1987):

1. English	63
2. French	34
3. Spanish	23
4. Arabic	22
5. German	8
6. Portuguese	7

The extent to which languages are studied as foreign languages could serve as another indicator of their importance as ILs; as a rule, it may be assumed that the more a language is used for international communication (in the narrower sense), the more it is studied as a foreign language. Unfortunately, world-wide comparisons of various languages as to the degree to which they are studied as foreign languages are not readily available. The only figures which are readily accessible are those of foreign students studying in the mother tongue countries of the following six languages (according to Conrad and Fishman (1977) for the older figures of some of the languages; according to the writer's findings from the same source (*UNESCO Yearbook*) for the other languages and for newer figures):

	1967	1986
English	156,403	409,920
French	44,078	142,480
German	39,178	96,172
Spanish	25,161	10,821
Italian	16,957	34,720
Russian	16,100	?

The data are not complete, since the number of foreign students (per country of provenance) is not always given for every mother tongue country of each language. In particular, the figures are incomplete for Spanish, which is underrepresented here; figures are entirely missing for Russian for 1986. Nevertheless, the overall tendency may be assumed to be correct. The figures presumably also correspond roughly to the overall degree to which the respective languages are studied as foreign languages worldwide—with the exception of Spanish, which is probably studied to a similar extent as is German and even clearly exceeding it in certain regions, particularly in North America. The foreign students represent those learners of the respective language who, as a rule, acquire solid skills in it and therefore are, at the same time, most likely to actually continue using it for communication afterwards.

A closer look at certain domains provides some insight into the actual use of various languages for international communication. Most revealing are, of course, the typically 'international domains,' i.e., those with high proportions of international

communication. Of these, some data relevant to this study are available for the domains of economy, diplomacy, and science.

In which languages do international business contacts mainly take place? An answer, admittedly preliminary, is provided by the German Chambers of Commerce (Ammon 1991: chap. 7.3), which on the basis of their extensive experience regularly issue recommendations for German companies as to which languages to choose for business contacts with other countries. This is particularly important for sales purposes: here, the choice of a language is a much more sensitive issue than in the case of buying. Even allowing for this sensitivity, one may find the recommendations somewhat biased towards German (which is natural, given the geographical location of the authors). For the year 1989, the six languages below are recommended for the following number of countries (for some countries, several languages are given):

1. English   122 (sole language in 64 countries)
2. French   57 (sole language in 24 countries)
3. Spanish   26 (sole language in 17 countries)
4. German   36 (sole language in 1 country)
5. Arabic   12 (sole language in 0 country)
6. Portuguese   8 (sole language in 0 country)

These figures should be weighed against the economic strength of the languages, as given above: just listing the number of countries can be misleading, especially with respect to a language's importance for international business communication. If the economic strength of the languages were taken into consideration, Japanese would probably have to be moved up, and French somewhat down as regards their importance for international business.

In the area of diplomacy, a language's status in the UN is of considerable importance, since this has some impact on its status in other international political organizations and conferences, as well as on the language training of diplomats in a number of countries. The following six languages are 'official,' and at the same time 'working' languages of the UN (the distinction between official and working languages has been largely blurred in the late twentieth century): English, French, Spanish, Russian, Chinese, and Arabic (Ostrower 1965: 405–31). German has the lower status of a 'documentary' language, i.e., one into which more important documents are translated (Tabory 1980: 9). The privileged status of official languages in the UN is due to one or several of the following attributes: being an official language in a great number of member countries (English, French, Spanish, Arabic); having a great number of speakers (Chinese); representing a mother country

with significant political and military strength (Russian).

Another indicator of a language's importance in diplomacy is its use in the texts of treaties between countries. Particularly revealing with respect to international communication is the asymmetrical use of a language or its use as a lingua franca in treaty tests. A language is used asymmetrically if it is the national, official language of one of the countries involved and is used for (an authoritative version of) the treaty, to the exclusion of other national, official languages of any of the involved countries. A language functions as a lingua franca if it is used without being the national, official language of any of the countries involved. During the period 1900–63, the following six languages were most frequently used asymmetrically or as lingua franca in treaty texts. (In the table, the first number indicates the entire period 1900–63, the number in parentheses indicates the period from 1950–63. Source: Rönnefarth and Euler 1963.)

Asymmetrical use		Lingua franca	
1. English	56 (24)	1. French	49 (16)
2. French	53 (21)	2. English	26 (18)
3. Portuguese	11 (4)	3. Russian,	
4. German	9 (3)	Spanish	1 (1)
5. Chinese	6 (5)	4. Swedish	1 (0)
6. Italian	5 (2)		

The most spectacular change occurring in the period is perhaps the demotion of French in favor of English as a lingua franca. This may be connected with a general change in rank order between the two languages as to their importance in diplomacy.

In science, international communication has always played an important role. In particular, a sizeable number of printed publications in one language have always also been studied by speakers of other languages. The number of scientific publications in a language may, therefore, serve as a rough indicator of the amount of international communication which takes place in it. Figure 1 shows the share of the five most important languages of scientific publication in the time period 1880–1980. (Source: Tsunoda 1983. The figures were calculated as the arithmetic means, first of the five sciences, and second of all the national bibliographies included by Tsunoda.)

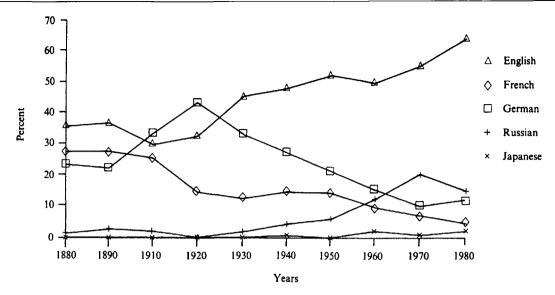
Figure 1 shows that whereas English, German, and French were somewhat on a par as languages of scientific publication at the beginning of the century, English has since clearly outstripped the other two. It seems, in fact, likely from other observations that international scientific communication largely happens in English, while the use of other languages is more and more restricted to the own language


Figure 1. Percentage of publications in different languages in the natural sciences.

communities. Similarly, new languages of scientific publication, such as Japanese, hardly serve for communication beyond their national market.

These data reveal some overall tendencies. English clearly is, in the late twentieth century, *the* IL in all important respects. It has outdone former competitors, even in their specific domains such as diplomacy (French) and science (German). This process has taken place in the course of the twentieth century. Nevertheless, some other languages still play a limited role in international communication (even taken in the narrower sense), particularly French, Spanish, German, Russian, Portuguese, Arabic, Italian, Japanese, and Chinese. In particular, this can be observed in these languages' asymmetric use in bilateral contacts with speakers of even less widely used international languages. Thus, French will still often be used between a French person and, e.g., a Portuguese; German between a German and, e.g., a Czech; and so on. The choice of language in such bilateral (or multilateral) contacts has, however, not been studied systematically on a larger scale; neither has the choice of a lingua franca been studied comprehensively. By and large however, the tendency seems to be for English to be the most frequent choice by far in the late-twentieth-century world. English is in a certain sense the contemporary 'world language.'

3. Factors of Relevance for the Rise and Stabilization of an IL

How does a particular language become and/or stay an IL? The task of finding convincing explanations for the facts presented above and of identifying and evaluating the reasons behind them is no less difficult than specifying macro-sociological factors in general. Such factors cannot be studied experimentally, because the circumstances cannot be manipulated (as would be necessary for such studies), and because the possibilities of doing statistical analyses are very limited for want of a sufficiently large number of cases. Nevertheless, some preliminary insights can be extracted from the available empirical and theoretical findings.

The question why a language becomes an IL should not be confused with that of a language's spread, even though the two issues certainly are related. In particular, the question why certain languages which were imposed by conquest (as in the case of colonization) became firmly established in their new area, while others did not, is of relevance in this context. A number of factors have been identified here: first of all, a colonial rule of long duration (e.g., the long-lasting British versus the short-lived German colonial rule); a high degree of multilingualism in the colonized territory (the imposed language thus becoming indispensable as a lingua franca); and, after decolonization, the continued existence of tight economic ties with the former colonial power (Fishman et al. 1977). The imposed language became, of course, firmly established particularly in cases where colonialism was accompanied by massive immigration from the colonial power (and later on also from other countries), such that the indigenous populations were virtually eliminated together with their languages, as was the case in the Americas and Australia.

623

The factors which establish a language as an IL have varied a great deal in the course of history. Thus, victories in major wars seem to have been a factor of some importance in modern times. For instance, English was established as an official language of the League of Nations after World War I, because, among other things, the US President insisted on English along with French being the official languages of the Versailles Treaty (the treaty which included the covenant of the League of Nations); German and Russian, being the languages of the defeated war parties, were not considered. Similarly after World War II, none of the languages of the defeated countries became an official language of the UN, whereas Russian, this time the language of one of the victorious powers, did. In contrast, French was not challenged in the nineteenth century as the (sole) language of peace treaties, even after the defeats of 1815 and 1871.

Military victories alone, however, have never been sufficient to establish a language as an IL. Extreme cases are the military successes of the Huns or the Mongols in medieval Europe, which in no way sufficed to make their languages international. Even a long-lasting political control over a defeated country does not necessarily establish the language of the victorious power as an IL. This is illustrated by the case of the Turks, whose language receded to their own country when their reign of hundreds of years, in some places even a thousand years, over the countries of the Middle East and of Southeast Europe came to an end. Economic strength, often accompanied by scientific and cultural prominence, seem to be the most important factors in establishing and maintaining an IL. Weakness in these respects seems to be the main reason why Russian presently is losing its status as an IL in Eastern Europe with the Soviet Union's military and political control over this region coming to an end. Contrariwise, the success of English as an IL in this region may be due to its economic and cultural or scientific strength compared to German, despite the latter language's long tradition there as an IL and as the language of a geographical neighbor.

One other factor of considerable importance deserves to be mentioned: an established IL stabilizes, even strengthens, itself in this function (Lieberson 1982), as it appears most attractive for being studied as a foreign language, and therefore is the 'normal' choice in contacts between speakers of different languages. For an established IL to be substituted by another language in this function requires a clear superiority of the latter in relevant areas such as economic strength of its language community, etc.

4. Native IL-Speakers: Privileged or Not?

It has often been suggested that people who do not speak an IL natively should be envied for being forced to study foreign languages with all the advantages which such a study implies, such as mind-training, insights into different cultures, awareness of linguistic relativity (see *Sapir–Whorf Hypothesis*). In contrast to these somewhat abstract blessings, the privileges of native speakers of an IL are more immediately evident, particularly if their language is the major IL, the 'world-language,' i.e., in the 1990s English. First of all, such native speakers are not forced to study any foreign languages in order to communicate internationally, but can spend their precious time on other, perhaps more rewarding endeavors. (This does not, of course, prevent them from studying foreign languages with all the said blessings involved.) Thus, they have a real choice, in contrast to the members of other language communities. Second, they are, as a rule, linguistically superior in the IL to non-native speakers of the IL, i.e., they can express their ideas more precisely, more correctly as to grammar, more elegantly, and more fluently; their discourse will therefore often be more convincing. Such advantages may not be relevant in all situations; in some, however, they certainly are, as, for instance, in diplomatic or business negotiations, or in discussions between scholars or scientists, especially when they take place in front of an audience.

However, one person's privilege is another's disprivilege, as is felt quite acutely by many communicators. Thus, among German scientists, a considerable number clearly feels disprivileged vis-à-vis English as the dominant language of science (Ammon 1990b). Many of them (25 percent) professed difficulties even in reading English, over a third (38 percent) in understanding the spoken language, and more than half (54 percent) in writing it. Even those who did not explicitly mention the latter difficulties were often handicapped in their written communication, since their secretaries usually were unable to handle English (88 percent of them). No wonder then that more than half (58 percent) of this sample of German scientists claimed that producing a text in English caused additional expenses (for translators, for corrections by native speakers, and/or for typing). Consequently, a considerable number of the scientists confessed to not being willing (at least on some occasions) to participate in scientific conferences (19 percent) or publication projects (33 percent) if English was the required language; similarly, they would abstain from other contacts with colleagues if such contacts had to be in English (25 percent). Similar difficulties may be expected in other groups for whom it is essential to communicate internationally. These difficulties are probably less serious in language communities with a longer tradition of having to use another language for international communication, as such communities have more or less adjusted themselves to the situation; however,

certain difficulties probably remain even for them in one way or another.

Still other advantages (or, as the case may be, disadvantages) arise from the fact that an IL, particularly if it serves for various functions, tends to be brought up to date constantly. Here, members of the IL-community have better access to the current terminology than do members of other language communities. Modern terminology, in particular technical terminology, is often taken over in its original, untranslated form by the non-IL, thus—among other things—increasing the gap between experts and lay people in the non-IL-communities.

For all these reasons, it is by no means astonishing that all larger language communities try to spread their language internationally, to the best of their abilities; that is, they try to increase their languages' degree of 'internationality' (Ammon and Kleineidam 1992). Even the major countries of the English language community are heavily engaged in such endeavors, in spite of the international dominance which their language has already gained (Phillipson 1991: chaps. 5, 6). If successful, such endeavors are also economically rewarding, since a more prominent IL will, as a rule, also be studied more intensively as a foreign language—to the advantage of the language teaching industry, as well as of the language teachers and linguists of the respective countries.

5. Artificial ILs: A Utopia?

The problems of ILs have often been closely associated with those of artificial languages proposed as ILs (e.g., Burney 1966, Pei 1966: 128, 131, see *Artificial Languages*). Such proposals have a long tradition, materializing in Europe as early as the seventeenth century. But it was not until the nineteenth century that projects were launched which, for at least some time, seemed to have real chances of success. The most successful of these is Lazarus L. Zamenhof's *Esperanto*, the first version of which was published in 1887 (*Linguo internacia*); a more refined version (1905, *Fundamento de Esperanto*) is in principle valid even in the early 1990s.

There is no question that Esperanto actually has become an IL and functions as such in the late twentieth century. However, it has fallen far short of the hopes that its creator and the members of the Esperanto Movement held out for it, namely to be *the* IL of the entire world, the means of communication between all human beings, no matter what their native languages, and an additional language for everyone. Esperanto was constructed in such a way that it would be particularly easy to learn (Roman script and regular orthography, an 'easy' phonology, simply morphology, etc.), no matter what actual language served as the learner's starting point. Thus, it also contains a fair share of the vocabularies of a number of different (European) languages. This

endeavor for 'fairness' was complemented by the idea that no language community should be at a disadvantage in international communication, since the speakers of the strongest of them would communicate in a foreign language just the same as would the speakers of the weakest language community.

That the project of Esperanto has thus far failed, is often ascribed to a number of more or less subtle reasons: e.g., structural insufficiencies (these could have been amended), its 'artificial' character, and so on. Rather, such reasons have served as arguments for those who rejected the entire project anyway. The real objections came from all those language communities or their representatives who hoped finally to realize their own native language as *the* IL of the world. Thus, Hitler and Stalin were among the most fervent adversaries of Esperanto. Some of the internationally dominant, or would-be-dominant, language communities did not fight the idea openly, but simply lent it no support whatsoever and instead promoted their own language as an IL; here, the major English-speaking countries are examples (see *Linguistic Imperialism*).

The Esperanto project has certainly been a utopia in that it presupposed that the powerful language communities would give up their linguistic advantages in favor of weaker language communities, allowing for a 'fair' solution to the problems of international communication. What those powerful language communities actually did in order to guard their vested linguistic interests seems to be in accordance with no less than a sociolinguistic 'law,' whose existence the 'Artificial IL Movements' have failed to recognize. It is, however, an open question whether such a sociolinguistic law (as sketched above) is a human universal, that is, whether it will determine all future development. If that were indeed the case, it would imply that a 'fair' solution to the problem of international communication, whether or not it was realized using an artificial language, would never have a chance.

Language Adaptation and Modernization
S. Bowerman

1. Introduction

'Language adaptation' refers to linguistic change, whether deliberate or spontaneous, whose goal is to adapt a language to the changed or changing needs of its speech community. The term is nearly synonymous with 'language modernization,' as the needs of a speech community are often a function of the times. Coulmas (1989: 1) argues that the term 'modernization' is less suitable, as it is often taken to refer to the present day. Language adaptation is a relatively new term in sociolinguistics, but the phenomenon affects all languages at all times.

The field of language adaptation and modernization largely intersects with that of language planning (see *Language Planning: Models*), in that a language is sometimes deliberately adapted to fulfill new roles. Natural language adaptation is spontaneous, and is unconsciously undertaken by its own speech community. Intervention is only necessary when a language, previously excluded for some reason from certain domains of use, suddenly needs to be used for those functions. It is therefore desirable to distinguish between linguistic change that comes about naturally, and that which is forced.

2. Factors Influencing (Deliberate) Language Adaptation
2.1 Dominance and Domain Exclusion

Many of the world's language communities are dominated in some way by another language community that is politically, economically, or numerically more powerful (cf. Tollefson 1991: 14). The dominant community's language becomes the medium for the higher domains of language use (see

Linguistic Imperialism; *Power and Language*) such as government, media, education, technology, and commerce, to the exclusion of the dominated language. Because the dominated languages are excluded from these higher domains, their lexicons, for example, do not keep up with the development of the dominant language as new terms are coined to describe new phenomena and experiences. The need for language adaptation is often recognized when there is a change, or a push for change, in the social structures that keep the dominance relationship between language communities intact. When this happens, and the (previously) dominated language is required as a medium for the higher domains, it is often found to be inadequate in terms of technology, modes of expression, etc.

Domain exclusion also impacts upon a language's speech community on a social level. A language that is excluded from the higher domains of language use is reserved for the lower or more basic domains: i.e., the home and community environment. This means that they will not be perceived as tools for economic advancement, and will consequently suffer from low status and prestige (see *Language Planning: Models*; *Linguistic Imperialism*). The language becomes stigmatized, even in its own community, and members of the language community who seek economic advancement will seek to acquire the dominant language. If the status of a language in such a position is not improved, it may well face obsolescence.

The post-colonial experience of many African and Asian nations in the mid-to-late twentieth century was a proving ground for the dominated indigenous

languages. The colonial languages had almost invariably been used as media for the higher domains, to the exclusion of the indigenous languages (Phillipson 1993: 112, chap. 5). The demise of colonialism meant that many countries were faced with a dilemma: whether to retain the colonial language as a high-domain medium, or replace it with one or more indigenous languages. Retaining the colonial language carried unpleasant connotations; but it was already developed enough to cope as the medium of a modern industrial state, and was entrenched in that role (Schmied 1991: 19). The indigenous languages, on the other hand, had been excluded from the higher domains and had neither the status nor corpus (see *Language Planning: Models*) to cope with their new roles. Although the indigenous languages were often instituted as symbolic official languages, the colonial language was retained for higher domain use in most cases (Schmied 1991: 20). Although the dominance of colonial languages, particularly those that offer global access, is all but assured (Laitin 1992: 181), there is a concerted effort for the functional expansion of indigenous languages.

2.2 The Transition From Oracy to Literacy

The move from oracy (see *Oracy*) to literacy (see *Literacy*) also creates a need for language adaptation. Indeed, the need for a written language where there was none before reflects a drastic change in the social structure of a community. There are (at least) two ways of fulfilling this need: the adoption of an already written language for these purposes, or the adaptation of the oral language to writing. Most societies have had to face this transition at some point in their history, whether this developed naturally or was thrust upon them from outside. Thus, the written language may differ completely from that which is spoken—which, as Coulmas (1989: 13) points out, is to be expected as speech and writing serve different communicative functions. Moreover, writing in the initial stages of the transition from oracy to literacy is usually the domain of an elite few. However, the adaptation of an oral language to writing reflects a change in the communicative function of that language, which in modern times has spread to the rest of the society. Whereas the 'undiscovered' world coped for millennia without writing, illiteracy in present times is viewed as a scourge.

Coulmas (1989: 12) notes that literacy does not necessarily stimulate language adaptation *per se*; but it serves as a tool for carrying out the process. A written language can easily be codified into a set of rules to be transmitted through education. This in turn affects the acquisition and use (particularly in the higher domains) of a language.

2.3 Attitudes and Language Maintenance

As with any language planning measure, it is the attitude of the people for whom language adaptation is to be undertaken that will determine whether or not it is successful. One crucial factor in forming a community's attitude is the degree to which the language will be useful, i.e., the domains to which a particular language gives access (Phillipson 1993: 79, 80, Cooper 1989: 100, chap. 5). Loyalty to a language and culture is another factor affecting the maintenance of a language. Although the revival of Irish in Ireland has turned out to be little more than symbolic, it is the loyalty of the Irish to their language that led to its extensive adaptation, even though English serves all the language needs of the majority. Languages that are neutral i.e., do not carry ethnic connotations, are more likely than others to be used as languages of wider communication. The neutrality of Swahili in east Africa led to its being extensively adopted as a national language in Kenya and an official language in Tanzania, and therefore to the extensive expansion of its functional range (Cooper 1989: 102).

3. The Process of Language Adaptation

3.1 Two Aspects of Adaptation

The process of equipping a language to deal with the realities of its speech community involves two aspects: one external to the language (involving the speech community) and one internal to the language (involving the structure of the language itself). In order for a language to be successfully adapted, that language must be widely used by its speech community in the domains concerned. This requires not only the elaboration of its lexicon, but also the boosting of its status. Adaptation and modernization through language planning is at an early stage: it is the implementation of language planning measures by a speech community that tells us whether the language has been successfully adapted or not.

3.2 Adaptation Through Status Planning

A common way of boosting the status of a language, and facilitating its adaptation and modernization, is through functional reallocation. Thus, a language previously excluded from the higher domains is allocated to those domains (Cooper 1989: 99, 118). These measures take time to be implemented: before a language can be properly used in a domain from which it was previously excluded, it has to be developed as a medium for that domain.

After their independence from colonial rule in 1962 and 1963, respectively, Tanzania and Kenya wished to establish a national African language in the place of the colonial one (Laitin 1992: 91). Swahili was the natural choice, having few 'tribalist' associations and a long history with the liberation movements (Laitin

Table 1. Terminology development in South African languages.

Method	Example
Calquing: direct translation, especially of compounds	English *cellphone* > Afrikaans *selfoon*
Loan words: borrowing a word, or the sound of a word, by another language	English *cellphone* > Sotho *selula founo*, Zulu *iselula*
Transliteration: use of the Classic stem to coin an equivalent	English *computer* > Xhosa *ikompiyuta*, Zulu *ikhomputha*
	English *silver* > Xhosa *isilivere*, Zulu *isiliva*
Extension of meaning: use of existing words, but broadening the meaning to include more modern concepts	Zulu *bafana bafana* (reduplication) = 'the boys'; extension of meaning to the soccer team, i.e., young male competitors on the international soccer scene
Neologism: new words created from within the target language	English *unleaded petrol* Afrikaans *ongelode petrol* (Creation of the verb *lood* 'lead,' past participle *gelode* 'leaded' from Afrikaans noun *lood* 'lead.')

1992: 91–2). In Tanzania (then called Tanganyika), Swahili was proclaimed as the language of state and public functions, and shortly thereafter became the 'major language of Parliament,' and was introduced as 'medium of instruction in all public primary schools' (Massamba 1989: 63). Although Swahili still faces serious competition from English, its adaptation and modernization have been widely accepted.

3.3 Corpus Adaptation and Modernization

3.3.1 Terminology Development

In order to fulfill its role as a high-domain medium, a language's corpus (lexicon and grammar) must be sufficiently developed. In cases where a language has been excluded from a domain it now wishes to occupy, its terminology and perhaps modes of expression need to be adapted to its new roles. There are various ways of adapting terminology, taking the target language system into account. It can be achieved through neologism, calquing, transliteration, and meaning extension (Alberts 1998: 233). Alberts (1998) provides some examples of these four methods of terminology development from South African languages, adapted here in Table 1.

As can be seen from some of the examples in Table 1, terminology development must take the target language into account: and we see how calquing and borrowing adapt from the sound system of one language to the other. Grammar is also an important device in language adaptation, and, particularly, terminology development. Table 2 shows how new coinages in Irish were applied to existing grammatical structures. O'Baoill (1988: 116) gives the example of the creation of an Irish term for 'lithograph,' and some of its derivatives. The new lexeme is a Hibernized borrowing from English, to which productive derivational morphemes are applied:

Languages also reflect their adaptation to a new or changed social order by getting rid of certain elements that tie them to the past. The reform of

Table 2. An example of terminology development in Irish.

English term	English derivational morphemes	Standardized Irish borrowing	Irish derivational morphemes
lithograph		liteagraf	
	-er		-ái
	-y		-áiocht

Turkish under Attatürk in the 1920s saw all Persian and Arabic loan-words expelled from the standard Turkish lexicon (Cooper 1989: 154, citing Heyd 1954). Similarly, some sectors of the French government have tried to block the number of loan words entering into French usage (Appel and Muysken 1993: 164).

3.3.2 Grammatical Development

The development of a grammar to suit modern or high domain purposes often results in a simplification of grammatical forms that are considered unwieldy, anachronistic, and unsuited to scientific and commercial discourse. Grammatical development may mean bringing the grammar of a language more into line with that of a dominant language. For example, there have been some attempts to bring the grammar of Irish more into line with that of English (Greene 1972: 15). Developing a standard grammar for Modern Hebrew from Biblical Hebrew processes, as well as innovation, in Israel spurred the creation of a multitude of new word forms. Grammar can be an especial problem in situations where there are a number of varieties of a language. In order for the language to be adapted to modern roles, it requires codification, and therefore standardization (see *Standardization*). Thus, where more than one form is found across varieties, one must be chosen as the standard. This applies to all aspects of the corpus.

3.3.3 Orthography and Spelling

These are two more aspects of the corpus, which are taken into account when conscious adaptation and modernization takes place. Orthography refers to the script that is used to represent the spoken language, and spelling refers (roughly) to the way it is used.

When a language is selected for adaptation and modernization, an orthography needs to be selected for it. If the language has never been written before, an orthography must be created—a process known as graphization. If, however, an orthography already exists, a decision must be made as to whether this system should be retained, or a new system found. This process is known as regraphization (Cooper 1989: 125, 154). Christian missionaries graphized most of the oral languages of southern Africa in the nineteenth and twentieth centuries. Generally, a Roman script was imposed and the spelling system of the missionaries' nationalities informed the orthography and spelling. While graphization is one aspect of language adaptation, regraphization is also important. The change in orthography reflects a change in society. An early example of this was the development of the Cyrillic alphabet, so that biblical and ecclesiastical texts could be translated into Slavic languages. More recently, Turkish adopted a Roman script in place of the Persian orthography it had used before (Haugen 1972: 170, citing Heyd 1954). Orthography can have powerful symbolic value for a speech community (see *Orthography*). In the 1930s, the Soviet government imposed the Cyrillic script on non-Russian languages within the USSR (Mesthrie et al. 2000: 391). Since the disintegration of the USSR, however, a number of these languages have had the non-Cyrillic script reinstated. Mesthrie et al. (2000: 391) cite the case of Moldavia: in August 1990, the Moldavians held a 'Language Festival,' celebrating the reintroduction of the Latin script. A developing adaptation process is also evident in Chinese and Japanese, which are adapting to changing functions by *adding* a Roman orthography, to facilitate the learning of these languages phonetically (Crystal 1995: 313, Sugito 1989: 117).

3.3.4 Standardization and Harmonization

These two terms apply in different ways to the same phenomenon: one language, which has many distinctive varieties in the same area. In some cases, like that of Irish (O'Baoill 1988: 111) or Swahili (Massamba 1989: 61), the varieties are widely recognized by academics and speakers as being varieties of one language. In order for the language to be adapted to a function, it needs to be stabilized and codified, and therefore standardized, and an orthographical/terminological/grammatical form is chosen from one of the dialects and held up as the norm. Otherwise, one

Table 3. Equivalent terms in Xhosa, English and Zulu (Adapted from *The South African Multi-Language Dictionary*).

Xhosa	Zulu	English
ifoni	ithelefoni	telephone
imoto	imoto	motor car
umbane	ugesi	electricity
ilayibri	ilabhulali	library
ikompiyuta	ikomputha	computer

dialect will be chosen as the standard, and all its forms held up as the norm by society as well as language planners (Cooper 1989: 134).

Harmonization is a form of standardization, but operates across varieties that are regarded as closely related, but distinct, languages. In essence, harmonization is an attempt to build one standard language from a variety of closely related languages (and all of their respective varieties). The harmonization (also 'unification') question in South Africa was revisited in 1989 by Neville Alexander (1989: 64), who proposed the harmonization of the seven major indigenous languages into two standards:

(a) Standard Nguni, comprising Xhosa, Zulu, Ndebele and Swati.
(b) Standard Sotho, comprising South Sotho, Pedi and Tswana.

Harmonizing the indigenous languages of South Africa would eliminate the need to adapt and modernize every one of the 7 languages that make up Sotho and Nguni. The harmonization of these languages could begin with new terminology, which can be coined as illustrated above. Table 3 illustrates similarities and differences between the Nguni languages:

The similarity between these two languages is striking, and shows the close relation of the languages to each other. Differences in vocabulary and pronunciation appear minor, but are significant to their speech communities that may be concerned that linguistic assimilation means political assimilation (Msimang 1998: 167). Those involved in language harmonization will have to liase extensively across languages to avoid being perceived to value one variety or language group above another.

4. Conclusion

Language adaptation and modernization is essential to the evolution and indeed, survival of any language. The linguistic change brought about through adaptation reflects the dynamics of the society in which it is used. The fact that intervention is sometimes necessary links the field with that of language maintenance: the adaptation of a language to fulfill modern functions is surely a mechanism for language

maintenance. It ensures that a language remains valued by its own community and others.

Language Development
H. R. Dua

The concept of 'development' has been extensively employed in social sciences to an increasingly large number of entities and embraces a wide range of meanings. Its application to language by linguists and language planners is a recent phenomenon. The notion of language development has assumed a great importance because of the role of language in the development of nationalism and nationality formation, the expansion of education and mass media, and the growth of culture, science, and technology. This article first clarifies the conceptual dimension of language development and then characterizes the nature of language features relevant to it. Following this it argues against the unidirectionality and universality of language development models. Finally, it discusses some theoretical and methodological issues involved in measurement of language development. The concluding remarks highlight the future work and prospects in the study of language development.

1. Conceptual Dimension

Perhaps the first explicit formulation of the notion of language development was attempted by Ferguson (1968). Ferguson maintained that judgments of backwardness or limited development of a language could not be made on the basis of linguistic structure. However, he identified three dimensions relevant for characterizing the nature and degree of language development: graphization, standardization, and modernization. In elaborating these dimensions he did not consider how they can be measured, weighted, and summed up to arrive at the degree of language development. Moreover, he interpreted narrowly the notion of language structure and ignored several other issues crucial to language development.

Since Ferguson, no considerable achievement has been made regarding the conceptualization of language development and its measurement. However, the notions of standardization and modernization have been differently interpreted in the context of

language planning and related to language planning processes. Fishman (1974) represents an integration of Ferguson's dimensions of language development with language planning processes of selection/implementation, codification, elaboration, and cultivation. He considers the dimensions as possible resultants existing along a continuum of the repeated application of the processes. However, he does not specify, apart from giving certain instances, what points can be established along the continuum, how the language planning processes relate to these points, and how language development can be measured in terms of the dimensions.

Two crucial issues need to be considered to make the concept of language development more comprehensive and to render it more useful in language planning theory and practice. First, what the linguistic features relevant from the point of view of development are and whether the dimensions mentioned by Ferguson adequately represent them. It is obvious that two important features have been ignored, though perhaps implicitly recognized in connection with modernization. The first is the quantum of material production in a specific language which includes not only the specific output of codification and elaboration efforts but also the creative, scientific, technical, and other forms of literature. The second is the number of domains in which a language is used or is intended to be used. The domains of use not only reflect the functional status of a language, but also its level of development. While the various linguistic features amenable to development may be considered independently for analytical purposes, they are intimately related and mutually reinforce each other making measurement of language development an extremely complex task, if not an impossible one. This is evident from the theoretical and methodological issues involved in language measurement.

Second, it is necessary to distinguish between the process and the product of language development. The process of development of a particular linguistic feature involves implementation, evaluation, codification, elaboration, etc., and is spread over a period. The product of language development on the other hand needs to be specified both in quantitative and qualitative terms. It is essential not only to evaluate the total output in the form of specific material, explicit norms or varieties of registers, styles and genres but also to consider how far the output is relevant, useful, and wide in range. The congruence between the process and the product of development indicates the success of language planning and ensures systematic and comprehensive language development.

2. Language Features and Development

For an adequate explication of the concept of language development, the language features can be distinguished in relation to language structure, language use, and language material (Dua 1985, 1989). Broadly interpreted, the language structure can be considered in terms of speech, writing, vocabulary, syntax, and forms of discourse. The nature and scope of these features can be characterized only briefly. Speech involves the development of the formal, semi-formal, and informal styles of speaking, the rules of pronunciation, and the norms of correctness. The development of writing implies not only the creation or adaptation of a writing system but also changes or modification in it in relation to its use for different purposes such as typewriting, printing, computer technology, etc. It also includes the development of orthographic and spelling conventions and formulation of rules for simplification, unification, or systematization of spelling and orthographic subsystems. The development of vocabulary may be considered with respect to the different types of vocabulary, basic, technical, and scientific, the range of abstract and generic terms for different disciplines, the degree of precision, consistency and flexibility in meaning, and the output of words through borrowing, coinage, and derivation. The nature and scope of syntactic development is less clear than vocabulary. It may be tentatively considered in terms of the property of intellectualization in grammar which manifests itself in syntactic devices that allow for 'the constructions of elaborate, yet tightly knit, compound sentences, as well as the tendency to eliminate elliptic modes of expression by requiring complete constructions' (Garvin 1973: 27). It may also involve development of new constructions, rules for foregrounding, coherence, and text organization. Finally, the development at the discourse level may be characterized with regard to the functional differentiation and specialization as related to registers, styles, and genres suitable for scientific, technical, literary, journalistic, and other types of functional prose, and the creation of models of reviewing, abstracting, reporting, drafting, and other such forms of specialized writing.

The level of language development related to language use can be characterized on the basis of the number of domains in which a language is used, and the description of the clustering, ordering, or ranking of the domains of use. It further depends on the oral and written modes of communication and the frequency and pervasiveness with which a language is used in different domains.

The production of different types of creative, original, and translated materials can provide a more concrete basis for the characterization of language development. It would, therefore, be extremely useful to develop a scheme of different types of materials. The following types are suggestive only: reference materials, including dictionaries, thesauri, glossaries,

nomenclatures, manuals, grammars; creative literature belonging to different genres; scientific and technical literature; literature in social sciences and humanities; journalistic literature; and textbooks for different levels of education.

The developmental status of the linguistic features discussed above can be specified on the basis of the developmental indices which include standardization (see *Standardization*), codification, elaboration, and cultivation. Standardization implies whether a linguistic feature has attained uniformity, whether uniformity is explicitly or implicitly recognized, whether there are different models or centers of standard, and whether norms of standard are rigid or flexible. Codification of a linguistic feature indicates whether its development has been recorded or not, and if recorded, in what form and to what extent, and whether the codified information is easily available. Elaboration implies whether the development of a linguistic feature shows more than one standard form used for different purposes. For instance, there might be different kinds of fonts used in printing or different types of dictionaries for specific users or purposes. Cultivation involves norms of correctness, efficiency, purity, and esthetics that are invoked in the development of a linguistic feature. The nature and scope of the developmental indices as characterized above were not, in the late twentieth century, fully understood, and their characterization and transformation into scalar values for measurement of language development can be considered still an open question. Furthermore, the development of all the linguistic features may not be equally evaluated with respect to these indices.

The characterization of developmental indices for evaluation of the developmental status of a linguistic feature can be made more useful in terms of what Neustupny (1974) refers to as the characteristics of language treatment patterns. He has suggested four characteristics for studying the treatment patterns: systematicity, theoretical elaborateness, depth, and rationality. For instance, it might be asked how far the standardization of a linguistic feature as elaborated above is systematic, based on theory, and is deep and rational. Thus the characterization of linguistic features and developmental indices along with their characteristics provide a sound framework for considering the nature and degree of language development.

3. Models of Development

Though language development cannot be dissociated from nonlinguistic development, the relationship between the two is far from clear. Another significant issue concerns whether the so-called 'developing languages' pass through similar or different stages of development than what is attested in the case of already developed languages.

As regards the relationship between linguistic and nonlinguistic development, Neustupny (1974) takes an extreme position. He has distinguished between three socioeconomic stages of development which he maintains have a one-to-one correspondence with language treatment patterns and models of language teaching. He distinguishes primarily between policy and cultivation varieties of language treatment patterns. He maintains that not only do the stages of socioeconomic development correspond to specific language treatment patterns but also that the less developed societies are characterized by a high degree of arbitrary social and linguistic heterogeneity and therefore show a predominance of policy approach, whereas the developed nations are linguistically homogeneous and focus on cultivation of code.

Neustupny's thesis has been questioned by several scholars on the basis of data from different situations. Jernudd (1977: 43–8) points out that the policy and cultivation approaches to language development need not necessarily be mutually exclusive. The tradition of language treatment in India, according to him, is characterized by the coexistence of policy and cultivation approaches which 'cyclically share the limelight' (1977: 44). Even Sweden is not found to present a very 'clean' case for assigning it to a 'cultivation' or a 'policy' approach. A 'developed' speech community could be found in any nation, developed ('modernized') or not. Jernudd (1977: 48) concludes, therefore, 'that there is no simple link between the development of a nation and the degree of development of its constituent speech communities.'

Since there is no simple and direct link between the linguistic and the nonlinguistic development, the developing nations need not necessarily pass through the same 'stages' of language development and reach some similar modern outcome. This is further supported by an ecological perspective on development which implies that 'development' depends on language situation, social system, economic processes, and other environment features considered as 'input' at a particular time yielding a specific 'output' given a certain degree of planning. This raises two significant issues from the standpoint of language development and language planning. First, it might be asked what kind of language planning and language development can coexist with what kind of societal conditions. Second, it might be considered whether language diversity is incompatible with national development, modernization, and language development.

The issues discussed above have been further clarified by Fishman (1974: 84) who compares the linguistic and nonlinguistic development on the one hand, and the experience of the Western and the non-Western societies on the other. He points out that

'the basic sociohistorical orientation in both fields points a complex constellation of continua with respect to the outcome of development and the processes of planning.' He finds a great deal of difference between the Western and non-Western societies with respect to the primary and secondary development which, according to him, 'is increasingly calling into question any simplistic notions to the possibility of universal and panchronic unidirectionality with respect to development and developmental planning.' He points out that the process of language development in the developing societies not only encapsulates centuries but also shows a discrepancy between expectations and rate of improvement not known in former centuries. He claims that language development may not only be instructively different as a whole today in comparison with former times, but it may also be variable with respect to certain domains and processes. Hence Fishman concludes that the developing nations must develop their own models of language planning and language development compatible with their language situations.

4. Measurement of Language Development

Even though the measurement of language development is essential for evaluating the vitality of language and the success of language planning, the issues involved in it have not been explored systematically. This is primarily because of inadequate understanding of the theoretical and methodical problems involved in measurement of language development. First, it is essential to understand the relative value of various linguistic features and their contribution to language development as a whole. This issue is complicated for several reasons. The nature and scope of linguistic features may differ from one language to another under different sociolinguistic situations. A particular feature may take some time before it manifests its impact on or contribution to language development. The effect of the feature may appear sooner or later than expected or there may be a different outcome altogether. Thus the weighting of linguistic features for their contribution to language development as a whole is complicated partly because of a differential salience of features and partly because of time and/or effect lag in their development.

Second, the summation of the value of all the linguistic features is no less complicated since it is not clear as to how far a particular linguistic feature is independent of the other. Without understanding the nature of interaction or independence between the linguistic features it is difficult to assess adequately the contribution of a linguistic feature to development. For instance, the development of a writing system has far-reaching implications for development of literary tradition and production of language materials. The latter is intimately related to the role of language in education and the degree of bilingualism in it. This is clear from the Indian linguistic situation. While Hindi shows a clear lead in quantitative terms over English in the production of periodicals during the decade 1971–81, English retains the top position in qualitative terms with respect to the periodicals of science, engineering, and technology. Notwithstanding the growth of periodicals in Hindi, both English and Hindi show a stable complementary relationship due to their role in education and the degree of bilingualism in them. Thus the interaction between the linguistic features on the one hand, and their interaction with sociolinguistic phenomena on the other make it extremely difficult to arrive at an independent developmental score of linguistic features for the purpose of summation.

Finally, the consideration of intertranslatability between developed and developing languages as a measure of language modernization (Ferguson 1968) has confused the issue of measurement of language development. In the first place, intertranslatability as a measure of language modernization implies that in spite of the different 'input' conditions of developing languages due to various sociolinguistic parameters they are assumed to pass through the same 'stages' and end up with some similar modern 'outcome' (Dua 1987). However, even the similarity of 'outcome' between developed and developing languages based on scientific discourse or technical terminology cannot be taken for granted. It has become sufficiently clear that accuracy, efficiency, and exactness of technical terms cannot be achieved in isolation from the general vocabulary, that the specific theory of terminology is language sensitive and that there is a dynamic interaction between special and general language usage which shows creativity, specificity, and uniqueness in language development (Cluver 1980).

In the second place, the degree of intertranslatability cannot be properly determined due to certain methodological considerations. There does not seem to be any valid single comprehensive theory of translation which can provide criteria for different modes of translation, the nature and scope of equivalence of translation in different modes, the selection of topics and forms of discourse for translation, and the relative value of both the form and content of texts of translation (Dua 1987, Fishman 1974, Newmark 1981).

It appears, therefore, that not only have the problematics of measurement of language development not been adequately formulated but also that it has been led into unwarranted directions and problems on both the theoretical and methodological grounds by considering it in terms of intertranslatability.

5. Future Work

Language development is crucial to national development and modernization of linguistically heterogeneous developing societies on the one hand, and success of language planning theory and practice on the other. The utility and relevance of the notion depends upon a deep and explicit understanding of the conceptual dimensions of language development along with a systematic characterization of language features. It further depends upon the theoretical and methodological developments in the measurement of language development rigorously on the basis of developmental indices and their characteristics. This requires a great deal of empirical research in different sociolinguistic situations and language planning contexts. Both the theoretical and methodological research on language development should be able to provide answers to the following questions. How is a particular language underdeveloped or inadequately developed? What is its degree of development? Regarding what characteristics and in relation to what functions is it developed or underdeveloped? What kind of language planning and sociolinguistic conditions are conductive to language development? How does the process of language development interact with socioeconomic conditions and developmental processes on the one hand, and the product of language development on the other? How are the modalities of time, rate, resources, and strategies of implementation related to the nature and degree of development? There could be many more questions. The point is that the notion of language development is potentially rich and vast and at the same time highly demanding from the points of view of theory, methodology, and research. The high expectations raised by the notion can be fulfilled depending upon the future developments in the theory of language development in particular and of language planning in general with respect to the issues discussed here as well as the others that might be raised on the subject.

Language Diffusion Policy

C. G. MacLean

The promotion of a language by a government outside the government's territory may be achieved in a number of ways. The evidence of history is various and often paradoxical. Military advances have usually resulted in the spread of the victor's language—or at least parts of it—but the effect has sometimes been only temporary. Missionary activity, not necessarily funded by government, has helped to spread some languages, but in many contexts missionaries (see *Missionaries and Language*) have aimed to make contact in the language of those they wish to convert. Policies of either persuading another to speak one's own language or of learning to speak another's language can be equally imperialistic in politics or religion or commerce.

Propaganda, religious or political, is generally more likely to be effective if it is in the language of the target audience. Likewise, many commercial activities are seen to require the use of the language of the target market: in even the strongest countries, lack of language ability restricts companies from trading abroad.

Tourism is noteworthy: in 1992 France was reported to be the most popular tourist resort in the world. Though the French government is eager to preserve and promote the use of French outside France, it would be unwise to do this in the literature promoting France as a tourist resort, and perhaps it should expect the strength of tourism in France, even with a copious provision of phrase books, to have no more than a marginal effect on the learning of French in schools abroad.

Radio and television have brought their own challenges and techniques. Radio sidesteps some problems of literacy and language learning: one recorded voice can be heard by millions, many of whom may be illiterate, and the one voice may offer instruction in a new language. Television language may be dubbed or subtitled, essential processes if the television programs are to be sold to the target viewers.

While the above factors have all been related historically to language promotion, none may be simply correlated to the proportions of the world population now speaking certain languages. Neither is there a discernible correlation between the numerical supremacy of the major languages (see Table 1) and efforts, as seen in the examples that follow, by governments to promote languages. The promotion of a language is at best a slow and unpredictable process. And the promotion may be significantly and suddenly reversed: compare the learning of Russian in Europe and beyond in the early 1980s and the early 1990s.

This article provides some examples of language promotion by governments in the late twentieth century: the languages are German, French, Hebrew, and English—the last promoted by several governments. All cases reflect, though in different ways, an acceptance of an obvious reality, i.e., that people outside a government's territory have need to or can readily be persuaded to learn the language or languages spoken in the country of that government. Also, all the cases here cited reflect, in various degrees, a combination of self-assurance and self-assertion.

Clearly there is a strong commercial element in most language promotion, but governments tend to give priority in their reports, program proposals, and promotional literature, to loftier aims, with claims that knowledge of the language will allow closer international links to be established. Also, more specifically, offer is made of access to and appreciation of a culture—literary, artistic, social, historical, etc. More precisely, cooperation is made available in fields of scholarship and professional expertise, not least science and technology.

Such activity is at times competitive: 'We have learned to market Britain's strengths against fierce international competition,' said Sir David Orr,

retiring chairman of the British Council, in his introduction to the Council's annual report for 1990–91. And: 'How to resist the Anglo-American Steamroller? It is so powerful ... ': see Sect. 2.2.

The information about Canada (Sect. 2.3) differs from what is provided about other countries in that it relates to the entire Canadian aid program. Noteworthy in the context of this article is the fact that Canada has two official languages, English and French. Canada's internal commitment determines in some measure the way it views its aid program: this program divides Africa into Anglophone and Francophone Africa. Any country, in providing aid, may well be influenced by its language, by history, or by geography, all of these probably being related. But the Canadian situation by itself highlights the interlocking of these three and might be used to assess, comparatively, the way in which the language interests of a country providing aid (of any kind) tend to confirm and promote the use of a language or languages in recipient countries or regions.

An appreciable number of governments provide large sums of money and resources in aid of many kinds to other countries or to citizens of those countries. The cultural, educational, and arts elements of such aid vary greatly in proportion to the total sums. The proportion attributed to language promotion cannot be precisely stated or estimated, even when a specific sum is described as allocated under this heading, for there is inevitably some degree of language promotion in most contacts between donor and recipient.

One sector of aid to developing countries (as of all aid between countries with different national languages) which may be expected to promote language is that of scholarships and study grants enabling people to spend time in the donor country. This form of provision may have long-term benefits for the donor country but may be counterproductive long-term as aid to a developing country, compared, for instance, with aid which encourages the developing country to build up its own resources of secondary and higher education—in institutions which are, however, less likely to give priority to the language of the donor country.

Looking to the late 1990s and beyond, so far as culture in its widest sense is concerned, attitudes to the promoting of a nation's language may perhaps come to be affected by internal tensions about the nature of the nation's culture. Immigrants and indigenous groups may assert their right to preserve their own culture, so may eventually argue that their numbers in the nation qualify their culture to be seen as part of a national amalgam, or what a former mayor of New York, David Dinkins, called a 'gorgeous mosaic' (*The Independent* June 22, 1992). They may then argue that they should not be

635

required to speak the official language of the nation: at which point it may be politically inconvenient for the national government to be promoting any one language. For instance, the 'melting pot' policy in the USA, as propounded by President Franklin D. Roosevelt, and envisaging the use of English by all groups in the USA, was resisted in the 1980s. Resistance of this kind is not confined to the USA. The Australian policy of assimilation was discontinued in the 1970s. It remains to be seen whether such resistance affects national policy on aid by any donor government. Certainly by the end of the 1990s policies of and pressures towards multiculturalism and multilingualism had advanced in a number of countries.

The culture argument becomes sensitive, too, if the suggestion is made that the culture brings with it a 'civilizing influence.' There have been times when one language more than another has been seen by some to be associated with civilized values. Below there are examples of unargued claims about 'democratic values.' However, the willing absorption of one foreign country's culture or values through the learning of its language, the reading of its books, and the appreciation of its arts may well in one person be accompanied by the determination to purchase a car or hi-fi equipment from another country, whose civilized values are not considered to be of material importance.

One other cultural issue arises in the context of language promotion. For example, in the information given below, three countries—the UK, the USA, and Australia—all actively promote the learning of the English language. It is to be expected that those who learn from teachers provided by these three countries will bear traces of the countries' distinctive accents and vocabulary. Here the cultural question is twofold: does the donor country attempt to suggest that one of its accents or dialects is superior and preferable? Then does the receiving country eventually develop its own form of the language learned—as of course the USA and Australia have done with English over the years?

The following examples show several ways in which countries perceive, and try to meet, the need for knowledge of their own language outside their own boundaries. They show, too, some of the ways in which such information is provided by government bodies in different countries. No two are easily compared, even within the English-language group. To some extent Germany and Australia may be compared, each in the context of influence on one region of the world. French and English may be compared in the context of historical, imperial influence. The UK and the USA merit consideration as two styles of promoting the same language worldwide. Canada is distinctive in its dual commitment. Israel is perhaps unique in representing a situation with no obvious comparison past or present.

All differ appreciably in output, areas of operation, level and style of funding, arguments deployed, and aims expressed. Together they raise a number of arresting questions about motivation and effectiveness, and not least (against the background of the languages known to be spoken by many and those spoken by but a few) about the likely, possible, and desirable ways in which the popularity of languages here considered, or of any other, will rise or fall.

In this context, three sets of statistics merit thought.

First, UNESCO figures for 1989 (see *Statistics: Principal Languages of the World (UNESCO)*) show that the total number of English, French, German, Spanish, and Portuguese speakers, though all numerically in the top 12, represent only 24.8 percent of the entire world population.

Second, of the total number of English speakers, in the UNESCO figures, 23.2 percent are classified as 'potential' (i.e., principally learners rather than mother-tongue speakers), and this number of 'potential' speakers is 48.4 percent of the total number of 'potential' speakers of all languages in the top 12.

Third, such figures may also inform reflection on the fact that (according to *The Independent* of January 8, 1992) in 1992 Radio Finland transmitted a weekly five-minute news bulletin, '*Nuntii Latini*,' in Latin across the globe—perhaps the most minuscule promotion of any language anywhere, in this case not the language of the broadcasting country. Latin was at one time more forcefully promoted, and to some effect. *Sic transit gloria mundi.* Thomas a Kempis's saying is described in Brewer's *Dictionary of Phrase and Fable* as 'a classic statement on the transitory nature of human vanities.' The Latin phrase is intoned at the coronation ceremony of the Pope. On Vatican City State Radio, Latin features in daily broadcasts of the Mass. The words '*Laudetur Jesus Christus*' precede all transmissions and are then repeated in the language of the broadcast; '*Christus Vincit*' is the station's interval signal (*World Radio TV Handbook*). For the rest, Vatican Radio is listed as broadcasting in over 30 languages, even including the international (artificial) language Esperanto (see *Artificial Languages*).

1. National Promotion

1.1 Germany

For the German government, cultural contacts are those not seen as political or economic. Most German organizations devoted to cultural and scientific exchange with other countries have their origins prior to the German economic crisis of 1930 and the Nazi dictatorship of 1933–45. From 1949 exchanges were resumed.

Academic relations are nurtured by the *Deutscher Akademischer Austauschdienst* (DAAD), the German academic exchange service, established in 1925, which promotes relations with other countries, particularly through the exchange of students and academics in all disciplines, including language. DAAD is publicly funded (in 1989 the Federal government and parliament contributed DM220 million), and also receives funds from the European Community and several national and international foundations and institutions.

DAAD projects include the DAAD *Lektoren*, teachers and lecturers who, for the most part, teach German at foreign institutions of higher education for a period of two to five years.

From its origins in the 1920s, the *Carl Duisberg Gesellschaft* (CDG) became an international exchange agency in the field of vocational further training. The developing countries became the organization's favored partners: some 7000 places were provided annually. In the 40 years after 1949 more than 100,000 persons from all parts of the world participated in the organization's programs. More than 60 associations of former scholarship holders were established in 50 countries. In Germany the CDG runs seven language centers with board and lodging facilities for around 700 participants. CDG funds are provided by the German government and the *Bundesländer* (constituent states), and German industry provides trainee places.

In the 1980s the German Foreign Office in Bonn commissioned from the Mannheim-based Institute of the German Language a survey on where German is spoken in the world: the report was entitled 'German-speaking Minorities.' Inevitably classification of varying groups was found difficult. The 1.6 million persons 'speaking German at home' in the USA top the list of the 27 countries; 112,545 speak German at home in Canada. Only about 100,000 of the 635,000 of German origin in Australia speak German at home: the decline is attributed to the Australian policy of assimilation (which was discontinued in the mid-1970s). Barthold Witte, head of the Directorate-General for Cultural Relations at the German Foreign Office, stated:

> Reliable information on the spread and usage of the German language in non-German-speaking countries constitutes an important planning basis for the intended expansion of language promotion for German native speakers and the descendants of German immigrants whose knowledge of German is still incomplete or no longer existent.
>
> (Inter Nationes, Bonn 1992)

UNESCO figures for 'total speakers' of the major languages show German as the twelfth: the figures for 'real speakers' show German as ninth. German is, however, the native tongue of more Europeans than any other. Figures from the Goethe Institute show German as the mother tongue of 110 million people. An article in 1989 says:

> The question of the position German will assume as a foreign language, the opportunities which will accompany the German language into the twenty-first century, will be decided primarily in Europe, in the European Community and in the countries of eastern Central Europe and Eastern Europe which are now beginning to open up.

The end of the Soviet Union and of its dominance over Eastern Europe made thousands of teachers of compulsory Russian redundant: to fill the language-teaching vacuum, German and English have been the main contenders. The Hungarian government decided in 1989 that, of 2000 Russian-language teachers, 1000 should become German-language teachers. For this the Goethe Institute provided teacher-training staff and materials and the German government provided financial assistance for courses in the Federal Republic. Also the German Industrial and Trade Association (DIHT) invited hundreds of functionaries from industry and commerce in the former Soviet Union to Germany: for these meetings the guests required knowledge of German, for which purpose the Goethe Institute provided intensive courses in the Soviet Union.

The Goethe Institute 'for the Cultivation of the German Language Abroad and the Promotion of International Cultural Cooperation' had a budget in 1989 of DM230 million from public funds, it had 149 branch offices in 69 countries. It provides over 1000 courses annually in German within Germany for 25,000 persons (1989 figure). In the early 1990s the Institute established new offices in Warsaw, Cracow, Sofia, Bratislava, Prague, Budapest, and Moscow. The Institute's libraries around the world have developed from purely lending libraries to information centers providing books, magazines, and audio-visual media. Video cassettes are provided for learning German.

The Goethe Institute administers a broad range of examinations in the German language. Looking towards the removal of European trade barriers in the 1990s, courses in German business terminology were provided in European countries. In the late 1980s an examination in Business German was devised jointly by the Goethe Institute, the DIHT, and the CDG. The Institute's promotional literature, accepting that German was already a second language in the Eastern bloc and the former Soviet Union, points out that 'more surprisingly' it is a second language in South America too, and the third language in Canada. Justifying the learning of German, the Institute argues that one-sixth of all Americans are of German descent, that Germans have been the largest ethnic group among American

immigrants, that every tenth book published in the world is in German; and that some important journals and papers, especially at research level, are not translated into English. Accepting that most young Germans have learnt English in school, the Institute says that German-speaking countries expect native speakers of English to learn German in order to establish trade—for others who seek to establish trade take that trouble.

The Institute sets out to counter claims that German is either a difficult or a harsh and ugly language (as suggested, say, by films made in the UK and the USA in the years following World War II). Knowledge of German, the Institute says, helps towards an understanding of several other European languages; it helps the tourist in Europe appreciate the part played by German-speaking countries in much that is significant in European history and culture; not least important, the German language is one of the common features between East and West Europe, so it may provide a link that can draw the two sides closer.

Deutsche Welle, the external broadcasting service of Germany, offers its listeners in Europe not only German-language programs but also 14 foreign-language programs. Since July 1990 the service has been broadcast via satellite as well as shortwave. Some other parts of the world are reached by satellite, all parts by shortwave—in a total of 34 languages.

1.2 France

> It is impossible to escape the question in everyone's mind: how to resist the Anglo-American steamroller? It is so powerful, in technology, business, and the audio-visual media. Ignorance of English is coming to be considered a sign of illiteracy. If Europe does not want to lose its soul, impoverish its culture, forget its history, it must take its pluri-lingualism on board.

The plea came from Alain Decaux, France's Minister for Francophonie (*The Independent on Sunday* October 21, 1990). He was speaking at a point when the French government had been reviewing the standing of the French language not only in Europe but around the world. It was a time, too, when there was turmoil in Eastern Europe, where those concerned with the teaching of the French language had to face a challenge as much from the German language as from the English.

The situation at world level was different as shown in Table 1. French government figures assembled about the same time as the UNESCO figures, show that around the world there were 253 schools, colleges, or lycées with French curricula aimed at serving 115,000 students, of whom 3700 were French. Some of the schools operate under local French embassy direction, some in cooperation with a range

Table 1. Number of speakers of the world's major languages (UNESCO 1989; in 1000s).

	Potential speakers	Real speakers	Total speakers
English	137,591.7	456,328.3	593,920.1
French	42,759.1	88,658.3	131,417.4
German	88.8	88,997.6	89,086.4

of local or worldwide bodies, the latter including the French Alliance. The French government decided to fund a reinforcement of teacher supply to these schools, partly to enable an improved flow of students from the schools to foreign universities, also of able students to French universities. The *Conseil pour l'enseignement français à l'étranger* (Council for the Teaching of French Abroad—CEFE) contributes to the integration of relations with all those bodies and people working in partnership with the schools abroad.

The French Ministry for Foreign Affairs works abroad along with institutes and centers, and with committees and affiliates of the French Alliance. There are 120 institutes and centers in 50 countries, all given the status of outside services to the Ministry, and all responsible for arranging conferences, exhibitions, concerts, films, etc. They provide language courses for around 180,000 students every year and they cooperate in a variety of ways with foreign universities. From 1990 onwards the language teaching function was given new impetus, with extended publicity, intensive short courses (some giving special attention to scientific and business French), and to improved libraries.

Every year 7000 French music discs are sent to nearly 500 foreign radio stations in 72 countries. French films are widely distributed by means of videocassettes. International coproduction of films and of TV series is encouraged. France offers, too, training courses in film production and in journalism.

Assuming that around 100 million people outside Francophone areas have learned French as a foreign language, the Secretary of State for Foreign Cultural Relations works to enhance cooperation in all teaching of the French language. Embassies and consulates are required to serve and to stimulate local services engaged in the teaching of French. Special support is given in both developed and underdeveloped countries to university courses in French and to bringing students of French to study in France.

The French Alliance has more than 1000 committees worldwide and serves more than 1600 localities. The network is particularly strong in Latin America. In the 1980s it expanded in Asia and in non-French speaking parts of Africa and it began to serve new areas in Japan, Fiji, Liberia, Morocco, Egypt, Korea, New Zealand, the Philippines, Sudan, and China.

The French Association for Promoting the Arts (AFAA), funded by both government and private enterprise, ensures support for the presentation of French arts and artists abroad, also it welcomes such ventures from abroad to France. The French government gives renewed emphasis to the promotion abroad of French literature and publishing (in 1989, 45 million francs were allocated to this). Five thousand copies are distributed of a monthly bulletin reviewing French books; the English version of this, *New French Books*, has a circulation of 2500. The bimonthly *Rendez-vous en France* (40,000 copies) is aimed at the educated, French-speaking foreign audience and covers many aspects of French life. Translation of French books, ranging from the humanities to science, is promoted in South America, India, and North Africa. In 1989 new resources were provided for ensuring an increase in translation of French books into foreign languages. New funds were devoted to a joint venture with Quebec to provide scientific works in French.

During the 1980s, looking beyond the academics, the better-educated, the literate, and the artistic in other countries, the French government accepted that in order to make contact with a truly international and sizeable world audience, France must establish a presence in radio (short, medium, and long-wave) and both large and small screen. The Ministry of Foreign Affairs was charged with the responsibility of coordinating efforts to set up a network of image and sound that would eventually cover most of the globe. Radio France International greatly enlarged its sphere of coverage—in Asia, by agreements with China and Japan on frequency allocation; in Europe and the Middle East by collaborating in radio services that provided some programs in local languages and some in French. Also private enterprise was encouraged to provide French cultural programs to be relayed by stations around the world.

A French initiative was launched in 1989 to strengthen and coordinate television services in Europe, and to ensure an open European market for programs. A Francophone channel was established, bringing together French, Belgian, Swiss, and Canadian companies, to reach more than 12 million people in Europe and, by cable, 1.3 million in Canada. Reception of French TV programs was extended to a large part of Italy and to Tunisia.

News programs, mostly originating in French national channels, are distributed by satellite and by cassettes to Francophone Africa, the Near East, Asia, and Latin America: they are received by 71 countries and used by 200 national and regional stations. The French agency AITV was reported in 1990 to rate fourth worldwide as a film/TV agency. Canal France International provides four hours daily a 'bank' for satellite broadcasts to North Africa, the Middle East, and Eastern Europe. France accepted the opportunity to use Olympus, the satellite for direct TV broadcasting, covering western Europe and offering program time to educational and cultural institutes.

The French Secretary of State for International Cultural Relations, along with the Ministry of Education, initiated the development of audiovisual programs for cultural broadcasting, distance teaching, and support for the French language.

1.3 Canada

In her introduction to *Sharing Our Future* (1987), a statement of the Canadian government's strategy for Canadian International Development Assistance (CIDA), the Honorable Monique Landry, Minister for External Relations and Industrial Development, stated that a country's foreign policy must be an expression of the mission of its citizens, of the country's character as a nation; that the message of Canada's strategy for development cooperation was, Canadians care; that the right Canadian resources should reach those most in need, when they need the help most; and that Canadians wished to create new partnerships, both domestically and internationally, in order to build a better world. *Sharing Our Future* reported the establishment in Canada of the International Francophone Center for Distance Learning.

The report, like annual reports of CIDA, was printed within one volume in English and French, with French text on inverted pages so that each language had a front cover and text running from page 1.

The statistics provided in the annual CIDA reports give information about a wide range of government support to many developing countries. Information about the support for Africa reflects the bilingual situation within Canada itself, in that Africa is referred to in terms of Anglophone Africa (Fig. 1) and Francophone Africa (Fig. 2), and CIDA reports use maps presenting CIDA's oversimplified view of the division. Many languages other than English and French are, of course, spoken in Africa.

The flow and exchange of personnel, in numerous professions other than those concerned with education and language, are inevitably language-conscious and require specific language competence. For those developing countries, not only in Africa, where levels of literacy are low, the promise of aid from abroad poses challenging questions related to priorities in language learning and competence, especially at secondary and higher levels, not only in those sectors of the community required to know an official language which has been bequeathed by past imperial rule.

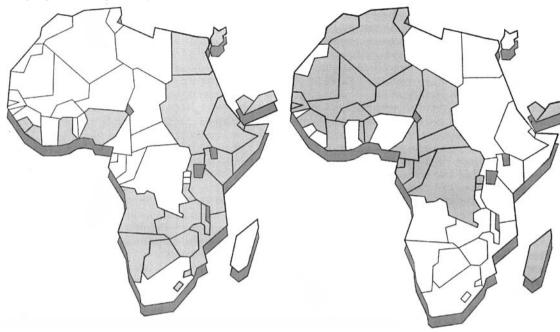
In the year 1989, students and trainees supported by CIDA were categorized in 32 subject groups (from Accountancy to Transportation) and totaled 11,021. Within that total, 272 were listed under Languages


Figure 1. Anglophone Africa (courtesy of the Ministry of Supply and Services, from CIDA Annual Report 1989–90).

Figure 2. Francophone Africa (courtesy of the Ministry of Supply and Services, from the CIDA Annual Report 1989–90).

and Linguistics, 655 under Education, and 105 under Arts and Humanities. The three largest categories were Management and Administration 2175; Engineering and Technology 1339; and Computer Sciences 1182.

CIDA works with Canada World Youth and Canada Crossroads International to involve young Canadians in international development. Each year these organizations arrange over 500 exchanges between young Canadians and young people from developing countries.

Radio Canada International in 1991 relayed programs from the English and French networks of its parent company, the Canadian Broadcasting Corporation. It provided newscasts in English to Asia and Europe, and in French to Africa and Latin America. It broadcast full programs to the Middle East in Arabic, to the former Soviet Union in Russian and Ukrainian, to China in Standard Chinese, and to Latin America in Spanish.

1.4 USA

The United States Information Agency (USIA), known abroad as the United States Information Service (USIS), operates as an independent foreign affairs agency within the executive branch of the US government. Its mandate is: 'to present abroad a true picture of the United States, to promote mutual understanding between America and other countries, and to counter attempts to distort US policies and objectives.' USIA programs have always been directed to overseas audiences.

The US government's first large-scale entry into information activities abroad began during World War I, then dwindled to almost nothing until 1938 when steps were taken to counter German and Italian propaganda aimed at Latin America. In 1942 the Voice of America (VOA) was created to counter adverse foreign propaganda, and the Office of War Information was established. In the immediate postwar years the need was seen to replace arms with words ('This is a struggle, above all else, for the minds of men': President Harry Truman in a speech known as the Campaign of Truth). In 1953 President Dwight Eisenhower created the USIA, the name restored by President Ronald Reagan in 1982 for an organization by then incorporating overseas information programs, educational and cultural exchange programs, the Voice of America, and Television (Worldnet) and Film Services.

> You have informed us truthfully of events around the world and in our country as well, and in this way you helped us to bring about the peaceful revolution, which has at long last taken place ... You will have to inform us about how to create democracy, because we are now beginning to build it, to renew it after long decades, and we have a lot to learn.
> (President Vaclav Havel, of Czechoslovakia speaking to Voice of America February 20, 1990)

Of the US$1093 million appropriated for all USIA activities in 1992, educational and cultural exchange programs received 22.1 percent: these programs included performing and fine arts presentations, book and library programs, and English teaching. Library programs are funded in 111 binational centers (BNCs) in more than 20 countries. Binational centers are independent institutions dedicated to promoting mutual understanding between the host country and the USA: English teaching is often a major component of the binational center's cultural, educational, and information activities.

USIA supports the development of English teaching curricula, textbooks, and training programs. This activity is intended to stimulate and reinforce academic exchange programs between the USA and other countries and to explain American life to audiences abroad. USIA promotes English language instruction at cultural and binational centers in 100 countries. More than 400,000 foreign citizens attend English language classes at these facilities. USIA English teaching officers provide professional guidance on teaching methodologies and materials.

The Agency publishes a professional quarterly for English teachers, *English Teaching Forum*, which is available in the US and abroad: over 120,000 copies of each issue are distributed in 133 countries. The Agency also publishes or supports 14 magazines in 21 languages. The quarterly journal *Dialogue*, first published in 1968 and distributed worldwide, contains articles selected from US magazines, the articles covering American society, politics, and the arts. *Dialogue* appears in 13 languages including English. The quarterly magazine *Topic*, distributed in over 40 countries in Sub-Saharan Africa is intended for young elites in the region and highlights USA commitment to African democracy and economic and social development. It is published in French and English.

USIA exchange programs include International Visitor, Citizen, and Youth Exchanges, as well as an extensive range of academic fellowships. Many academics from most countries in the world go to study in the USA every year.

USIA maintains links with or assists approximately 200 cultural centers and language institutes, approximately half of them binational centers, in nearly 100 countries. These centers conduct English classes, seminars on aspects of life in the USA, and arts and exhibition programs. Some centers are fully funded by USIA, while binational centers, autonomous institutions answerable to their own local boards of directors (local citizens and resident Americans), sometimes receive grants from USIA and may have staff supplied by USIA. Their English teaching programs are open to the public and generally attract large numbers of secondary school students. The direct English teaching programs are more targeted and cater to government and education officials, journalists, and USA Aid grantees but do allow others to enroll as space permits.

In 1989, of 90 binational centers, 78 were in Central and South America and the Caribbean, three were in Indonesia, two in Pakistan, one in Thailand, and six in Europe. There were no binational centers in Africa but USIA supported 15 English language programs in the region.

The Agency's English Language Programs Division has 17 English Teaching Officers and support staff in Washington, and 15 officers serving overseas as Country or Regional English Teaching Officers. Washington and field-based officers rotate regularly. All have advanced degrees in applied linguistics and/or TEFL (Teaching English as a Foreign Language), combined with experience as EFL (English as a Foreign Language) teachers, teacher training, or academic administration. The English Teaching Fellows Program recruits recent MAs in TEFL to increase the American presence and to help improve academic standards at overseas institutions, including binational centers.

In 1992, in an Eastern-European EFL Fellow Program, USIA was seeking applicants for posts as EFL teacher-trainers and ESP (English for Special Purposes)/EFL specialists to work with local EFL teachers in Poland, Hungary, Czechoslovakia, Romania, Yugoslavia, Bulgaria, Albania, Lithuania, Latvia, and Estonia.

USIA and the Voice of America cooperate in promoting English Language Teaching by Broadcast, a multimedia product developed by a US publisher and USIA.

1.5 United Kingdom

In the British Council annual report and accounts for 1990–91 the Director-General's review of the year reports that 'Demand for English teaching programmes and expertise, as a tool for communication, training, and the transfer of technology, remained buoyant—and, in Eastern and Central Europe, insatiable.' The report quotes Professor Svetlana Ter Minasova, of Moscow State University, addressing a conference organized by the Council, the BBC, and the English Speaking Union: 'Teachers of English have never been so important and so wanted and so unable to satisfy the cry for help. For very many people, English is the standard-bearer of democracy.'

Twenty-four English language projects for Eastern and Central Europe were prepared by the British Council in the first few months of 1991 (up to March 31). The biggest of these projects were for Poland, Hungary, and Czechoslovakia, with smaller ones promised for Romania, Bulgaria, Yugoslavia, and the former Soviet Union. Many of the projects involved the development of English language

641

teaching within national education systems 'reflecting the demand for English both as a vehicle for democratic values and as the point of access to expertise vital to the development of the region.' The projects concentrate on the key areas of teacher training and retraining, English for banking, government, finance, and tertiary education; British cultural studies; and resources and self-access centers for students and teachers of English. Almost 100 teaching posts and 30 resource centers were to be created using new funding from the UK Foreign and Commonwealth Office (FCO).

Other innovations reported included a joint venture with the British Tourist Authority and Lille Chamber of Commerce to promote British schools of English and British ELT publishers and examination boards; a project jointly funded with the UK Overseas Development Administration (ODA) and the Mexican government for an English teaching program involving eight universities in central Mexico; arranging high-level training for 25 teachers in Japan, paid for by Monbusho, the Japanese Ministry of Education; a program of ELT support in Turkey; an ELT resource center in Hong Kong for the higher-education sector, while 70 primary school teachers of English were trained at language schools in Britain and 300 at the British Council English Language Centre in Hong Kong.

Looking to the future the Council's annual report (1990–91) said: 'We have urgent priorities to extend our work in Eastern and Central Europe, the Middle East, Hong Kong and Southern Africa.' In seven years the Council's budget grew from £204 million to a projected £395 million for 1991–92 and the Council's overseas presence extended from 133 towns and cities in 81 countries to 162 in 90 countries.

The Council works in close collaboration with the UK FCO and UK ODA. In 1990–91 the Council's expenditure by regions in percentages was: Africa 28; Western Europe 19; Eastern and Central Europe 6; Asia Pacific 17; South Asia 14; Middle East and North Africa 8; Americas 8. In the same year the Council's expenditure by activity in percentages was: interchange of people 57; libraries, books and information 13; English language and literature 13; science and education 12; arts 5.

The Council's total receipts for the year (1990–91) were £362 million. Its sources of funding in percentages were: government grants 35; ODA agency 35; FCO agency 6; other agency 7; revenue 17. Council work for the arts was supported in large part by sponsorship from a range of business companies.

Teaching of English by broadcasts from the UK is the responsibility of the BBC World Service, but the British Council works along with the BBC in language promotion and teaching.

1.6 Australia

The International Development Program of Australian Universities and Colleges (IDP) has Australian Education Centers in Bangkok, Hong Kong, Jakarta, Kuala Lumpur, Manila, Seoul, Singapore, Suva, and Taipei. The centers offer guidance on Australian education, with information, counseling, and application processing to overseas students as well as promotion and recruitment activities of Australian educational institutions.

IDP is joint sponsor with the Indonesian Directorate General of Higher Education in sponsoring the Basic Science Bridging Program (BSBP) for staff from Indonesian universities. The program upgrades and refreshes the scientific knowledge and skills of science teachers.

Since many participants hope to undertake postgraduate work in Australia or other English-speaking countries, the study of the English language is an important part of BSBP. 'English is necessary for anyone seeking to become more qualified in science (even for those with no wish to travel or study overseas) since it is the most widely used language for scientific communication, and most scientific textbooks and journals are written in English.' Under IDP, staff of four universities in Java intending to apply for overseas study programs, may enrol in preparatory English courses conducted by Australian ELT advisors. The courses are provided in the Language Training Centers of the universities.

The Indonesia–Australia Language Foundation (IALF) is a self-funding body subject to Indonesian laws, and operates throughout Indonesia. Created by the governments of Indonesia and Australia in 1988, it aims to contribute to economic, social, and cultural development in Indonesia, and 'to promote mutual respect and understanding, particularly through the medium of high-quality English language teaching and training services.' Its information on education, disseminated in the English language, lays emphasis on 'creating a bridge between two cultures' and on the learning of the English language. IALF clients are Indonesian government departments, non-government Indonesian organizations, universities and other educational institutions, staffs of banks, hotels, etc, and private individuals. The Foundation is funded from Australian government grants; through charges to Indonesian organizations, governmental and otherwise; and through a range of contracts and fees paid by individuals.

IALF services include courses in English for students preparing to study in Australia, New Zealand, the USA, Canada, the UK, and other English-speaking countries. English courses offer preparation for the workplace, academic bridging programs, specialized writing, travel, and 'working in committees—Western style.' The Foundation provides consultancies, technical services, and testing on

English as a foreign language. IALF courses on Indonesian language and culture are offered to people new to Indonesia.

The English Language Center of Australia (ELCA), an affiliation between IDP and the University of the Thai Chamber of Commerce (UTCC) is located at UTCC Bangkok and serves those intending to study in Australia and other countries as well as those wishing to improve their English for business or personal reasons.

Radio Australia, the international broadcasting service of the Australian Broadcasting Corporation, broadcasts in eight languages to an estimated 50 million listeners in Asia and the Pacific. Its English service is broadcast 24 hours a day. (Other language services, broadcast regularly throughout the day seven days a week are in Indonesian, Standard Chinese and Cantonese, French, Tok Pisin, Thai, and Vietnamese.) The English language training programs are broadcast as part of the regular shortwave services to Indonesia, Thailand, China, and Vietnam. The lessons, developed in collaboration with specialist educational institutions in Australia, concentrate on aural comprehension and are supported by reading material which aims to ensure understanding of spelling and grammar.

In 1991 an initial series of 26 half-hour lessons was produced following a request from the Vietnamese government and the broadcasting organization Voice of Vietnam to provide support to their English language broadcasting efforts. Radio Australia's English lessons to China are supported by booklets and cassettes produced for distribution across China: these were launched in China in 1992 and sold in 18 branches of the foreign language bookstore in Beijing, the hope being that the service would be rebroadcast on domestic radio stations. In 1991 Radio Australia began a new series of programs, 'Study in Australia,' aimed at raising awareness in north and southeast Asia of educational opportunities in Australia. The series is available on cassette.

1.7 Israel

The State of Israel and Jewish society in Israel espouse the Zionist position according to which every Jew, anywhere in the world, is entitled, invited, and called upon, constantly and unceasingly, to immigrate to and live in Israel.

(Israel Government Year Book 1990)

The literature of the Academy of the Hebrew Language asserts that Hebrew is a cornerstone in the national and political rebirth of the Jewish people 'not only as citizens of a proud young state, but as members of a Jewish people with a long history and heritage'; that Hebrew is the expression of 'the Jewish cultural revival'; that it plays an essential role in

fusing Jewish exiles from 102 lands into one nation with one common language; that the Academy 'is the supreme authority in the most audacious linguistic experiment ever attempted: the adaptation to the computer age of a tongue unspoken for 1700 years.' Since the mid-1960s the Academy has supervized the Hebrew, including word use and pronunciation, used by Israel's Broadcasting Authority.

For some years after the creation of the state of Israel in 1948 the promotion of Hebrew was seen by some Jews to be in competition with a revival of interest in Yiddish. David Ben-Gurion, Israel's first prime minister, is reported to have said Yiddish sounded repugnant. While a more tolerant attitude has developed in Israel towards Yiddish Israeli resources of language teaching, both within Israel and in the diaspora, are concentrated on Hebrew.

If a professional person, say in Russia or the UK, wishes to work in Israel, the Israeli government, assuming that the family will settle in Israel, pays for six months' support within Israel of both parents and family. This and a variety of other forms of support to immigrants have continued since the 1940s. The teaching of Hebrew has been a strong element in the process of initiation.

As knowledge of the language of the country is essential to help integrate the many people constantly arriving from all over the world, the *ulpan* method was developed to aid the rapid learning of Hebrew. It consists of an intense course, usually of five months' duration, in which most newcomers acquire adequate proficiency for everyday communication.

(*Facts About Israel: Education.*
Israel Information Center 1991)

The term '*ulpan*' (from Old Hebrew 'a place to learn') is used in reference to a wide range of the teaching and learning of Hebrew outside Israel. In *A Short History of the Hebrew Language* (Jewish Agency Publishing Department, Jerusalem 1973) Chaim Rubin claimed that at the beginning of the 1970s there were signs of a tendency to equal a knowledge of modern 'living' Hebrew with personal commitment to the movement of Jewish awakening. This, he said, found its expression in the marked increase of the proportion of Hebrew speakers among young people, not only in the USA and Canada, but also in South America and Western Europe. It found expression, too, in the growing interest of academic youth in Hebrew studies, and in pressure for the development of Hebrew studies in universities. It took its most dramatic form, he believed, in the awakening of the 'Silent Jewry' in the former Soviet Union, among Jews who, at grave personal risk, set up private *ulpanim* for learning Hebrew. Such enthusiasm has helped to ensure that necessary resources are found. At times the Israeli government has made funding, resources, and personnel available

for the teaching of Hebrew in the diaspora. The Jewish Agency, the World Zionist Organization, in the UK the Zionist Federation Educational Trust (ZFET), and the Israeli government have all done much to promote the study of Hebrew throughout the world. Specially trained teachers have been sent out from Israel for periods from two to five years. Young people from abroad have gone to Israel to be trained as teachers of Hebrew. Hebrew language workshops have been formed, and crash courses provided for Jews wishing to visit Israel.

A major difficulty has lain in securing a supply of qualified language teachers, this because of the growing demand for the teaching of Hebrew within Israel itself, where immigrants have outnumbered the native population. But the teaching of modern Hebrew is ensured in many parts of many countries.

Language Planning: Models

A. Deumert

Language planning refers to deliberate, conscious, and future-oriented activities aimed at influencing the linguistic repertoire and behavior of speech communities, typically at the state level. Other terms which occur in the literature and which are partially synonymous with language planning are: language engineering; language management; language standardization (see *Standardization*); language determination; and language development (see *Language Development*). Language planning can be distinguished from language policy. Language policy describes the underlying political and sociolinguistic goals that are implied in the activities and measures of language planners.

1. Historical Background

The American linguist Einar Haugen (see *Haugen, Einar*) introduced the term language planning to the literature in 1959. Language planning is a long-standing practice and examples can be found in language history, e.g., the foundation of language academies from the sixteenth century which promoted the European vernacular languages against the dominance of Latin (see *Academies: Dictionaries and Standards*). However, only after World War II, when the newly independent and multilingual nations in Africa and Asia faced the question of selecting national languages for administrative and educational purposes, did language planning emerge as a separate area of sociolinguistic research, and began to develop its own descriptive taxonomies and explanatory models. Language standardization, national language selection as well as the support of linguistic diversity and the maintenance of minority languages have been prominent issues of language planning research during the past decades.

2. The Process of Language Planning

Based on his study of the dual standardization of Norwegian (i.e., the emergence of the two Norwegian standard languages *Bokmål* and *Nynorsk*), Haugen developed a fourfold model, which describes the kind of activities in which language planners typically engage. The model consists of four stages, which need not be sequential.

(a) Selection of norm: the process of selecting a regional and/or social language variety to fulfill certain functions in a given society or nation. The Norwegian standard of *Nynorsk* is a composite of the rural dialects, while the *Bokmål* standard is based on the Danish-influenced speech of the educated urban classes. In Kenya English has been selected as the sole official language; its neighbor Tanzania selected Swahili, the local lingua franca (and limited the use of English to certain legal contexts and post-primary education).

(b) Codification of form: the selection of a writing system and the establishment of linguistic norms through grammars, spelling rules, style manuals and dictionaries. The latter not only decide on the appropriate vocabulary, but also contribute to the standardization of spelling and sometimes pronunciation, e.g., Samuel Johnson's *Dictionary of the English Language* (1755) and Noah Webster's *The American Spelling Book* (1790) established the different spelling traditions of British and American English. In Yugoslavia Vuk Stefanovic Karadzic's grammar of 1814 and his dictionary of 1818 became the foundation of a common South Slavic literary language (Serbo-Croatian).

(c) Implementation: the gradual diffusion and acceptance of the new norm within the language community or territory (see *Language Diffusion Policy*). The process of implementation can involve overt marketing techniques to promote the use of the selected norm (including billboards, radio, and television skits) as well as legal enforcement.

(d) Elaboration of function: the process of extending the functions of the selected norm (legal language, scientific language, etc.). This includes terminological modernization and stylistic development (see *Language Adaptation and Modernization*). In Israel the Academy of the Hebrew Language has established committees to work on the development of Hebrew scientific terminology. Similar bodies have been instituted in other parts of the world, for example, in India (Hindi), Indonesia (Bahasa Indonesia) or Sweden, where the Center for Technical Terminology develops standard terminology for spoken and written Swedish. Elaboration is an ongoing process in every language, as there is a never-ending need to develop new terms for new ideas, innovations, and technologies. This ensures the use of a language in a variety of domains.

3. Status, Corpus, Prestige, and Acquisition Planning

An alternative descriptive model was suggested by Heinz Kloss (1969), a German linguist, based on the observation that language planners focus their attention either on linguistic aspects of the selected language or language variety (corpus planning; i.e., the production of grammars, dictionaries and spelling rules), or on the language's social status, that is, its functions in society (status planning; e.g., official language, provincial language, language of wider communication, medium of instruction, etc.). This binary distinction emphasizes the dual nature of language: language is a system of linguistic elements (the *corpus* or body of language), as well as a social institution and a communicative tool. Codification and elaboration are usually considered aspects of corpus planning. Selection and implementation belong to the domain of status planning.

Although Kloss separates corpus and status planning conceptually, the two dimensions closely interact with one another: the allocation of new language functions often requires changes in the linguistic system such as the development of new styles, discursive devices, and lexical items. Thus, the adoption of Tok Pisin, an English-based pidgin language, as one of the official languages of Papua New Guinea (status planning) required the elaboration of its vocabulary to provide terms for concepts related to the sphere of politics and legislation (corpus planning), e.g., lexical innovations such as *nesional baset* ('national budget'), *minista bilong edukesan* ('minister of education') (see *Pidgins, Creoles, and Minority Dialects in Education*).

Kloss's two-dimensional model has been extended more recently by R. L. Cooper (1989) and H. Haarmann (1990), who introduced the notions of acquisition and prestige planning. Cooper described those activities, which are aimed at promoting the learning of a language as acquisition planning. Unlike status planning which is directed at increasing a language's functions, acquisition planning is directed at increasing the number of users of a given language or language variety. Just as corpus and status planning are intertwined so are status and acquisition planning: new areas of use might attract new users and an increase in the number of users might support the allocation of new language functions (education, administration, technology, etc.). Corpus planning also interacts with acquisition planning. The publication of grammars and dictionaries is important for the development of teaching material and the implementation in the educational system. Haarmann has introduced the dimension of prestige planning to describe those aspects of language planning that are directed towards creating a favorable attitudinal background for corpus, status, and acquisition planning. This is particularly relevant in the case of low-prestige minority languages which often exist in a diglossic relationship with the area's dominant language and whose use has been limited to low-culture functions (see *Diglossia*). In order to make status changes of minority languages acceptable to the speech community, it is often necessary to first improve the (overt) prestige of the respective language or variety.

Both Haugen's and Kloss' taxonomical models are useful heuristics for the systematic description and categorization of the language planning activities carried out by individuals or institutions (such as academies, language societies, governments). However, they do not provide explanations for the success and failure of individual language planning endeavors, nor do they propose general principles on which to base future language planning.

4. Language Planning as the Rational Choice of Linguistic Alternatives?

Early models (e.g., Ray 1963, cf. also some of the papers in Rubin and Jernudd 1971) have approached language planning as an orderly and systematic process of decision-making, and have adopted a positivist and technical attitude to the solution of language issues in society. The decision procedure which underlies language planning efforts has been summarized as follows: once a linguistic problem has been recognized, language planners will specify the long-term and short-term goals of their actions, produce possible solutions, and carefully assess the costs and benefits involved in each of these solutions (cost–benefit analysis, Thorborn 1971). The most rational (economically, socially, and politically viable) solution to the problem will be selected and implemented. Finally, predicted and actual outcomes will be compared, and modifications are introduced if necessary. Lack of a uniform national language, the

absence of adequate scientific terminology, and the existence of widespread societal multilingualism have often been identified as problems by language planners.

The description of language planning as a process of rational decision making is based on several assumptions, most centrally the existence of a clearly defined decision-making unit (such as a government ministry or a language academy), which identifies a single set of goals, carefully assesses a range of alternatives, and ultimately selects that solution which maximizes benefits and minimizes costs. It is further assumed that the language-planning unit has the willingness and the ability to collect the information necessary for evaluating the alternative proposals, and that the infrastructure is adequate for the implementation of the solution. The following critiques have been formulated against these assumptions:

(a) In many cases language planners have only limited knowledge of the sociolinguistic facts of the country or area in question. Language surveys, which list, for example, speaker numbers, degree of bilingualism, patterns of language choice, and linguistic attitudes, are frequently incomplete and outdated. This is particularly true of many multilingual countries. The sociolinguistic structure of linguistic diversity is still poorly understood, and many languages and dialects still lack linguistic descriptions.

(b) Decision-making is always shaped by the socio-political context, and the assessment of costs and benefits is open to diverse interpretations which are socially and historically contingent. For example, to introduce Hindi (which is widely spoken as a second language in India), as the exclusive language of the government might be considered economically beneficial, as it would reduce the costs of administrative multilingualism. However such as policy would be felt unfair by speakers of other languages (high social/political costs). India has thus opted for a multilingual language policy (15 official languages, with Hindi as the *primus inter pares* and English as an associate official language). In other contexts, however, language planners have evaluated multilingual policies negatively as too costly and politically and socially divisive. Many African countries, for example, have selected only one official language, usually that of the former colonial power. A single national language was believed to support national unity as well as economic integration with the industrialized Western states. Monolingual policies, however, carry considerable social and educational costs as the former colonial language is usually only spoken by a minority of the population. Many citizens are thus excluded from political participation and post-primary education.

(c) Language issues are not necessarily the only concern of planners, and language planning has been employed to solve linguistic as well non-linguistic problems. In Quebec, for example, the Charter of the French Language (Bill 101), which demands the use of French in all areas of public life, also led to a change in the structure of the labor market which was previously dominated by English-speaking Canadians. In other cases, language planning has been applied to achieve national integration, liberation and equality, or to foster the power of the elite. To account for the diverse (and often unstated and intertwined) linguistic and socio-political interests in terms of an orderly decision-making model and systematic cost–benefit analysis is seldom possible.

(d) Language planning is not necessarily conducted by a central authority, which oversees the process of decision-making and implementation. It is often initiated and supported by informal networks or individuals, as in the case of feminist language planning. Not only is the feminist movement organizationally fragmented and thus lacking a clearly defined decision-making unit, but also its linguistic goals and language planning efforts have been rather diverse. Some initiatives have focused on disrupting the conventional structures of language and creatively feminized lexical items (such as the reanalysis of 'history' as 'his + story' and the use of the feminized form 'herstory'). Others have argued for the need to create a more women-centered language capable of expressing a female perspective (see *Gender and Language*). Most efforts have, however, been directed at neutralizing linguistic usage (e.g., 'chair' or 'chairperson' instead of 'chairman,' 'he/she' or 'they' instead of generic 'he'). Despite the decentralized nature of the feminist movement and the existence of various goals and linguistic strategies, its efforts towards linguistic equality were surprisingly successful. The use of masculine generic forms has declined considerably in most Western nations since the early 1970s and strategies of gender neutralization are today widely accepted.

A characterization of language planning as rationally organized by clearly specified planning bodies or institutions must be understood as an ideal case, which individual societies approach to varying degrees. More often than not language planning is 'a messy affair, ad hoc, haphazard, and emotionally driven' (Cooper 1989: 41).

5. Historical and Ethnographic Analyses: Explanation through Description

Language planning theorists in the 1980s and especially the 1990s have emphasized the ideological dimensions of language planning, which is always a political exercise and cannot be reduced to the application of specialized (socio) linguistic knowledge to perceived language problems. Cobarrubias (1983) has distinguished four main types of language ideologies: pluralism (i.e., supporting the co-existence of different language groups within a state or society); assimilation (i.e., asserting the dominant language as the medium of communication and marginalizing other languages); vernacularization (i.e., the selection and restoration of the local indigenous languages and their use in official functions); and internationalization (i.e., the selection of a non-indigenous language for national communication). Researchers such as James Tollefson (1991) have shown in case studies how language planning reflects and reinforces past and current relationships of economic, social and political dominance, and inequality. Others, such as Harold Schiffman (1996) have drawn attention to the role played by a community's linguistic culture, i.e., the behaviors, beliefs and values, historical experiences, religious or mythological traditions associated with a particular language (e.g., what do people think about their language?; what do they think about other languages?; how do they assess multilingualism?; monolingualism?; is there a strong bond between culture and language?, etc.). The community's linguistic culture is believed to function as an interpretative filter, thus influencing the formulation of language political goals, the specification of language planning measures and the responses of the community. For example, the decision whether to borrow linguistic items from other languages or whether to rely on language-internal word formation rules is often motivated by non-linguistic, cultural preferences, rather than the more technical principles of linguistic efficiency (easy to learn and use), clarity and regularity. In those speech communities where language constitutes a core value of the community and marks regional or national identity, vocabulary extension is typically characterized by puristic tendencies (e.g., France). Historical and ethnographic approaches to language planning, which relate the patterns of actual language use and choice to the historical structures of social and political domination and to the cultural beliefs speakers express about language, have contributed to a more in-depth understanding of the decisions made by language planners and the reasons why some proposals succeed while others fail.

As in the other social sciences, explanatory adequacy in language planning research is largely observational. Understanding is achieved through the careful description of the speech community's linguistic behavior, the discursive penetration of cultural belief systems, the sociopolitical conditions of language use, and the linguistic and non-linguistic interests of the different groups that are engaged in the language planning process. Since language planning cannot be understood in isolation from the complex sociohistorical context in which it is enacted, trans-historical generalizations and law-like predictions are rarely possible.

Linguistic Census
L. M. Khubchandani

Language information in the census provides a useful tool for the study of sociology of communication in general. Many countries, when conducting periodic enumeration of their populations' socioeconomic characteristics, collect information on languages in use in the society: language(s) spoken in the house-hold, language(s) in various public domains, knowledge of languages other than one's mother tongue, and so on. The techniques applied in the census are primarily of elicitation, and are not based on participation or observation at length. Demography as such is primarily concerned with the behavior of the 'aggregate,' and not with the behavior of individuals.

The Indian census has a record of presenting a fairly systematic account of mother tongues of the subcontinent since 1881, and of bilingualism since 1931, shedding light on the ethnic and linguistic composition of populations of the vast South Asian region (now comprising India, Pakistan, Bangladesh, and Burma). It is regarded as one of the most thorough-going inquiries into social structure ever to be conducted in any part of the world. Many European censuses highlight the extent of the spread of national and minority languages in different regions (Kirk 1946, Verdoodt 1990). The Canadian census has been eliciting language information since 1901. South Africa has enumerated languages of European populations since 1918.

1. Interpreting Language Claims

Language claims in the census deal with a somewhat abstract sociolinguistic reality. The mother-tongue assertions of different groups in multilingual societies could be merely 'tips of icebergs': much more remains hidden under the surface than is revealed through an individual's declarations. A language census accounts for information on one or more aspects of speech behavior:

  (a) population aggregates portraying a picture of language *usage* in a particular region or society;
  (b) head counts graded on the basis of language *competence* in a variety of skills (speaking, writing, etc.) in a particular language;
  (c) populations signifying unconscious attitudes and pressures of language identity, i.e., the data based on language *image*: 'what they *think* of their speech variety';
  (d) populations asserting conscious alignments characterizing the signals of language *posture*: 'what they *prefer* to be aligned with' in the circumstances in a region or society.

The data implicitly reveal the scope of manipulation through language returns.

It is estimated that some 5000 languages are spoken around the globe. Because of the bias in favor of clear-cut categorization, language information in many demographic accounts is often mistakenly handled like physical data (birth, death, sex) without evaluating subjective factors. There have been two basically different approaches among social scientists with regard to utilizing the language census as a tool for social planning. First, universalists show concern for soliciting statistical information on language in standardized categories to enhance human understanding; (a) framing of language questions for eliciting precise and unambiguous responses, (b) orienting the population to provide 'objective' responses, and (c) interpreting responses (Kloss and McConnell 1974). Second, pluralists lay emphasis on the *relevance* of questions specific to a context. Responses and interpretations are regarded as conditioned by ecological and historical perspectives of different sections of society.

Statistical data on language are often interpreted differently by the authorities and by the pressure groups in many countries. Many political agencies interpret language census rigidly, i.e., evaluating language information arithmetically (such as, numerical 'majority' versus 'minority') and incorporating compulsory changes in the administrative or educational structure based on the given information; for case studies on Belgium, see Levy (1960), on Canada, Lieberson (1967), and on India, Khubchandani (1976, 1983), Mahapatra et al. (1989).

Decadal language returns of the Indian census could be taken as a useful indicator of some of the attitudes to language underlying the speakers' assertions, and reveal evasion as well as fluidity which are not always apparent on the surface. Records of the Indian census during the post-independence period show two opposing streams that suggest the following.

  (a) There is anxiety to attain prestige by identifying oneself with a major language and not necessarily with one's native speech 'the first speech acquired in infancy through which a child gets socialized. It claims some bearing on 'intuitive' competence, and potentially it can be individually identifiable' (Khubchandani 1983: 45). An amazing example of this characteristic is the claim of 233 million speakers in the 1991 Census that 'Hindi' (proper) is their 'mother tongue' out of the total population of 337 million 'classified' under Hindi language (i.e., 69 percent); the remaining 31 percent speak

markedly different varieties of related languages (such as Pahari, Rajasthani, Maithili, Bhojpuri) for primary communication.

(b) There is inverted pride in 'exclusiveness,' that is, the tendency to assert one's own social identity as being distinct from that of others. Many tribal groups show this tendency because of their feeling of superiority to, or hostility towards neighboring groups.

One cannot justifiably claim to possess a standard measuring index of identifying one's mother tongue or the knowledge of other languages. The seemingly innocent questions asked in the census, 'What is your mother tongue?' could be projected as:

(a) language *first* learned or used (which favors the reporting of minority language maintenance);

(b) language *usually* used in everyday life (which favors reporting assimilation trends towards the dominant language); or

(c) *all* languages which the individual knows (which maximizes the number of speakers of the dominant language (Kirk 1946)).

Knowledge of the criteria employed is a great help in making critical evaluations of language.

Similarly, there is no clear-cut operational definition with which to quantify the knowledge of a particular language. Such knowledge largely depends on an individual's degree of awareness, subjectively interpreted on the basis of: (a) fluency, that is, spontaneity in expression; (b) intensity of use, that is, varieties of communication tasks being performed; (c) proficiency, that is, grasp of the standard variety; (d) knowledge of the script associated with that language; and so on. A perfectionist may hesitate to claim knowledge of a language in spite of having a fairly advanced grasp of that language but with which he is 'not satisfied,' whereas a trader may claim to know a number of languages merely on the basis of knowing a few phrases in those languages.

2. Politicization of Language Data

As language is primarily a time-and-space institutional reality, often political considerations such as the adjustment of district, state, or national boundaries on the basis of language tend to politicize pressure groups around language and influence the language returns of a region. Many censuses apply varying (inclusive and exclusive) criteria to boost the 'majority' claims or to minimize the importance of 'minority' groups.

Hence the tabulations of sociocultural data in a census attain only the appearance of precision. the Austrian census classified Yiddish as a variety of German (even though culturally it carries a distinct Jewish identity); since 1971, the Indian census classifies Bihari, Rajasthani, Pahari, and Chatisgarhi as Hindi. In Australia, 'Carinthian' is distinguished from the Slovenian language of Yugoslavia; Hungary treats Serbian and Croatian as separate languages, whereas the Yugoslav census treated them as one language (with bi-modal standards), Serbo-Croatian (or Croato-Serbian) until the 1980s, before the federation was split into five separate nations: Yugoslavia (confined only to the Serbian-speaking territory), Croatia, Bosnia, Macedonia and Slovenia); Russians treat Moldavian spoken on the Romanian border as distinct from the Romanian language.

Utilizing the inherent ambiguity in the terms 'language' and 'dialect,' various governments make intentional distortions in taking the censuses of their populations, such as applying varying criteria in the grouping of mother tongues into umbrella-like 'languages' or isolating them as distinct entities, as *perceived* by dominant agencies or pressure groups in a region. A normal pattern in these censuses emerges as: (a) maximization of the apparent proportion attributed to the dominant national language; and (b) corresponding minimization of the size of linguistic minorities. The British census tabulates language data in the framework of English speakers and non-English speakers, and thus the 1931 England and Wales census reported only 98,000 non-English speakers (i.e., monolingual Welsh speakers), though at the same time there were 909,000 Welsh-speaking people in the region. The 1931 Scottish census listed only 7000 non-English speakers in Scotland, though the population included 136,000 Gaelic speakers.

Fluctuations in language returns of the North-Central region in India, known as the 'fluid zone,' present an interesting case study of grouping over 330 'mother tongue' labels under a few generic umbrella labels, such as Hindustani, Hindi, Western Hindi, Eastern Hindi, Bihari, Rajasthani, Panjabi, Western Panjabi, Pahari, etc. One finds that language-*identity* patterns and language-*usage* patterns among different communities in the region are not necessarily congruent, resulting in many vacillating trends in the census declarations of mother tongues.

Shifts in declarations of mother tongue from one language to another in successive censuses, depending on the social and political climate, seem to be a frequent feature among 'fluid' speech groups in India. For example, bilingual Muslims oscillate between regional and religious identities when claiming their mother tongue. Urdu growth rates during the decade 1951–61 reveal the dramatic process of consolidation throughout the country—a 69 percent increase of Urdu speakers in India against the country's total population growth of 24.4 percent. Astounding increases in the claims of Urdu mother-tongue speakers in almost all states can be regarded as an assertion of cultural solidarity by bilingual Muslims through Urdu and the relegation of respective regional languages to subsidiary language status in their subjective evaluation of competence, in

reaction to the postindependence language politics in the country. What has happened in the case of Urdu is also true of Hindi, Panjabi, Maithili, Kui, Banjari, Nepali, Bodo, and many other Indian languages. This phenomenon demonstrates the magnitude of functional heterogeneity in linguistic communication characteristic of organically plural societies.

Bilingualism claims in the Indian census, by and large, reveal the extent of pressures developed among different speech groups for intragroup and intergroup communication. In a situation of multiple choice, different factors such as heterogeneity, demands made by dominant speech groups, contiguity of language borders, levels of education, occupational specialization, urbanity, and prestige contribute to the claims of regional languages, Hindi, and/or English as contact languages in a state. Communicative pressures exerted by prominent languages in each region of India, if they can be quantified in some ways, should be very useful to evaluate the individual and collective bilingual experiences (Hindi and regional languages based on the subsidiary language claims in the 1961 Census, Khubchandani 1983). These, then, can be correlated to educational and development programs in the process of language planning.

3. As a Tool of Social Planning

Correlational studies comparing the language factor with other relevant variables can help in understanding the speech phenomenon of human behavior in more transparent terms. The language census, as a tool for scientific inquiry, can provide useful insights into the scope of linguistic and sociolinguistic studies, and in relating to the sociocultural aspects of population dynamics such as: language and dialect relationship; standardizing the units for counting speech variation in a community; conceptual fluidity regarding mother tongue in plural societies; language claims reflecting change and stability in population; language as instrument as well as product of 'cohesion' and 'distance'; attitudes regarding one's 'own' and 'contact' languages in multilingual populations; diagnosis of communication environments in different regions.

Linguistic Habitus

I. Gogolin

Pierre Bourdieu's (1981) concept of habitus denotes a modality, which enables the individual to act routinely as well as creatively and innovatively. Central to Bourdieu's theory is the attempt to describe the dynamic relationships between the structural conditions of an individual existence, the individual's activities as a product of socialization under these conditions and the open-ended yet strictly limited capacity of the individual for action. In the process of socialization (see *Socialization*), a system of permanent dispositions is created in the individual, including sensitivity as one prerequisite for personal development. This system of dispositions and sensitivity is a necessary precondition for successful social activity.

Bourdieu emphasizes a circularity between *structure*, *habitus*, and *practice*. Habitus functions as an awareness-matrix, an action-matrix, and a thought-matrix for the individual; however, it does not alone determine behavior. A habitus is acquired under a certain set of social conditions, which Bourdieu calls 'objective structures.' To these belong the existential requirements, which characterize and define a social class. A habitus therefore is generated and regenerated by the specific objective structures of a class, and at the same time define and redefine, generate and regenerate the lifestyle and practice of its members. Bourdieu describes this circularity as follows: habitus function as 'structured structures, which are suitable to function and work as structuring structures' (Bourdieu 1979: 167). Implicit in a habitus is a tendency toward self-stabilization—despite the fact that socialization is not completed until death. New experiences are integrated in a habitus which leads to its constantly changing form whilst remaining relatively stable.

The term linguistic habitus thus refers to the set of dispositions in the field of language: to a person's notion of linguistic 'normality' and of 'good' language, to a society's notion of 'proper' ways of language behavior, of 'legitimate' language variations and practice. The term does not describe language as a means of communication in a narrow sense, but refers primarily to the symbolic relations and signs by which language becomes a medium of power (see *The Linguistic Marketplace*). Gogolin (1994) defines the monolingual habitus, which is common to the classical European nation states as an example of a linguistic habitus. In the process of their foundation in the eighteenth and nineteenth century, the basic and deep-seated belief was created that monolingualism is the universal norm for an individual and for a society (cf. Hobsbawm 1990). This idea was disseminated and traditionalized by institutions of the nation-state: jurisprudence, military forces, political, and administrative bodies. Probably most influential for the creation and dissemination of these fundamental elements of the concept of nation state were the modern state school systems, which were established simultaneously to the foundation of the nation state as such. Linguistic homogenization was the main motive for the development of public education systems. The establishment of one national language and of a monolingual national society was (and often still is) seen as essential for the success of the nation state, especially at the economic level.

In reality, hardly any nation in the world ever had a monolingual population. In most countries—especially in the Australasian, Asian, and African world, but also in Europe—people speak more than one, often many languages (see *Bilingualism, Societal*). Despite this reality, the deep-seated belief in monolingualism as natural in a society governs individual and public opinions towards language and language practice. In the cases of European nation states, this becomes obvious in connection with immigration. Roughly one third of the people under the age of 35 years in the member states of the European Unity are migrants, speaking other languages than the national language(s) of the respective state (see *Migrants and Migration*). For example, in the year 2000, more than 350 languages were spoken by children in London schools. Nevertheless, the European state school systems act as if they had monolingual populations. The teaching is centered on the 'legitimate' language of the state or the area, that is to say the national language or the official language of the region. The other languages are rarely taught at schools; children stay illiterate in their second or third language they live in. Consequently, they are unable to develop their other languages towards the most elaborated state (see *Bilingual Education*). By these mechanisms, the hierarchy and power relations between languages become stabilized. Those who have no or less access to the legitimate language are at risk of being excluded from participation and equal success in a society.

The linguistic habitus is the governing mechanism of these processes. The notion of linguistic normality was traditionalized in history, despite multilingualism. There is no collective remembrance of these historical events; the fact that this notion once was created and implemented explicitly has disappeared from collective memory. According to Bourdieu's theory, a habitus functions the better, the less conscious its owner is about it.

A variation of the monolingual habitus seems to be at work in multilingual nation states as well, due to the fact that there is usually one selected language of power. This may not be a national language. In colonial or post-colonial situations especially, the language of power very often is not a national language, which by constitution has legitimate status. Instead, it is the language, which guarantees survival and success in the linguistic market—mainly the language of the former colonists. Whereas in Europe, the standard national languages are usually considered the legitimate variant, in colonial situations symbolic power is linked to the languages of the former oppressors (cf. Goke-Pariola 1993). The linguistic habitus ensures the relative stability of these situations, and thus contributes to the durability of societies of marked disparities in power between different social groups.

Multilingual States
D. D. Laitin

A 'state' is a territorially bounded organization in the permanent business of rule. All states, at least in their early periods of development, have encompassed populations in which there are many speech communities, and therefore were in their origins multilingual states. (A multilingual individual is a person who is competent in more than one language; a multilingual state is a political entity in which there is more than one speech community.) For many states an important component in the business of rule has been to effect language change in the population within their boundaries so that all official communication can be transacted in the language preferred by the rulers. It is possible, through individual multilingualism, to have a single official language in a multilingual state. But, historically, the imposition of a single official language has fashioned monolingual societies, which provided a cultural foundation for a 'nation-state.'

A nation is a modern, socially differentiated society, in which most of the people imagine themselves to be members of a 'community.' Since uniformity of language creates an aura that all inhabitants of the state form a natural community, the homogenization of language helps to create, but is not a necessary condition for, a nation-state. Not all states become nation-states; many remain multinational, with each national community within the state relying on its own language. Societal multilingualism may persist because leaders do not seek to create language uniformity or because substantial numbers of people refuse to learn the language favored by the ruler. Why some states construct language uniformity within their boundaries and others do not remains an important research question in political science. Political scientists also seek to discern the consequences of different language outcomes in the process of state-building, especially for economic growth and democracy.

1. State Rationalization

The nineteenth-century German sociologist Max Weber used the term 'rationalization' to refer to the process of efficient and orderly rule. The development of a professional civil service, with a well-specified division of labor, was for Weber the essence of rationalization in the modern state. The establishment of sharp territorial boundaries, the standardization of the calendar, of weights and measures, and the issuance of a common currency are important examples of state rationalization.

A common language is a crucial element of a rationalization program. Legal uniformity is easier to assure when court decisions are delivered and recorded in a common language. Tax can be collected more efficiently and monitored more effectively if merchants all keep their books in the same language. State regulations can more efficiently be disseminated if translations are not necessary for compliance to take place. And territorial boundaries are easier to patrol if the population at the boundary speaks the language of its political center, one that is distinct from the language of the population on the other side of the boundary. Given these considerations, it is not surprising that rulers of states have sought to transform their multilingual societies into nation-states through policies that can be called 'language rationalization.'

Language rationalization policies usually entail the specification of a domain of language use (e.g., appeals court cases, or church sermons) and a requirement that the language of rule be employed within that domain. When rulers have established power over a territorially based speech community, they are easily able to induce some of its members to become bilingual, so as to translate documents from the language of the speech community to the language of the ruler. To the extent that political rule is stable, more and more members of the population will find it useful to learn the language of the ruling elites. Language rationalization is successful when there is a sufficient number of bilinguals among the speech communities with languages different from the official one so that the business of rule can be transacted in a single language.

In many cases of successful state building, language change is greater than rationalization would demand. On the individual level, rationalization requires only 'unassimilated bilingualism,' that is to say, that individuals use the language of the ruling elites only for specified domains. But individuals can move to 'assimilated bilingualism' where they use the language of the central elites for most domains, and use the language of their speech community only for family affairs. Finally, in some populations, 'assimilation' takes place, where virtually all members of the speech community become monolingual in the language of the political center. When this occurs, a 'nation' that is commensurate with state boundaries can most easily be imagined.

In the real world, there are no examples of the complete elimination of societal multilingualism. Certain minority groups retain their languages despite changes in the rest of the society; immigrant groups often retain the languages of their home area for some generations; and language shifts take place within a single language, yielding *de facto* multilingualism even when members of the various speech communities claim to speak the same language (e.g., African American English). Of even greater political importance, groups that had assimilated into the language of the political center may find themselves parties to a 'language revival' movement that challenges basic assumptions as to whether the country involved really is a national state. These sorts of questions persist in politics because there are no clear divisions between unilingual and multilingual societies, or between multinational state and nation-states. Ambiguity feeds political struggle.

Despite the ubiquity of minority speech communities, many states have successfully pursued language rationalization policies. Here we shall outline the processes of rationalization in France, Spain, and Japan, and discuss the anomalous multilingualism in Switzerland, which is clearly a nation-state.

1.1 Language Rationalization in France

In 1539 King Francis I issued the Edict of Villers-Cotterêts which established Francien as the only official language of the realm. At that time many related dialects, such as Norman and Picard, had more literary prestige, but the Francien dialect was spoken in the capital and the surrounding *Ile-de-France*, so it was politically more attractive. There were in the King's realm a number of German, Flemish, Catalan, and Basque speech communities as well. The many languages of the southern region, collectively called '*langue d'Oc*,' had long literary histories, and were not mutually intelligible with Francien. But the purpose of Francis's edict was not to change the language repertoires of his ordinary subjects from different speech communities; rather it was to give support to a national vernacular as opposed to Latin, which was the prestige language of education and law. The language of the court immediately changed to Francien. It was not until 1762, however, when the Jesuits were expelled from France, that Francien could replace Latin in higher education. Rationalization, then, was a long but successful process.

France nonetheless remained a multilingual state until the final third of the nineteenth century. As late as 1863, by official estimates, about a quarter of France's population spoke no French. The rigid centralization of administration organized by Napoleon, the rapid increase in enrollments in public education which supplanted the Catholic Church in providing basic literacy, and military conscription all worked to create in France a nation-state where virtually all citizens, in large part through sharing French as a mother tongue, imagine themselves as members of a common nation. The nation was not natural, however; it was created through policies of rationalization.

1.2 Language Rationalization on Spain

Spain was multilingual when the Catholic monarchs, Ferdinand and Isabella, presided over the final reconquest of the peninsula from Muslim rule. Castilian, Catalan, Basque, and Galician were the major languages of Spain. The Habsburg kings, following the treaties of Ferdinand and Isabella, respected regional differences in language and in law. Spain's wealth from overseas conquest, however, attracted artists and writers from all over Europe, and Castilian became a language of prestige throughout the peninsula. The literary florescence of the Golden Century (mid-sixteenth through mid-seventeenth century) induced well-to-do-families throughout the country to educate their children in Castilian.

It was not until 1716 and the Decree of the Nueva Planta, under Spain's first Bourbon King, Philip V, that Castilian became Spain's language for official business. A series of decrees in 1768–71 required all primary and secondary education to be in Castilian, and in 1772, all commercial establishments were required to keep their accounts in Castilian. Despite these laws, as is shown in the section on language revivals, multilingualism persists. Spain's status as a nation-state was never fully realized.

1.3 Language Rationalization in Japan

Japan, because it is an island and had insulated itself so long from foreign influence, is often described as the quintessential nation-state. Yet even in Japan, regional dialects (*hogen*) were quite distinct. The four major *hogen* groups are those of Eastern Japan (known as *Kanto*), Western Japan, Kyushu, and Ryukyu, each with subdialects. The Japanese Alps, dividing Japan east to west, helped form the most politically significant dialect divisions. There is a

considerable folklore about the deficiencies and lack of intelligibility of the eastern dialect in the west, and vice versa. Over the course of Japanese history, there were many forces which sustained language differences. The seventh-century borrowing of Chinese orthography created a division between written and spoken language which lasted over a millennium. In the Tokugawa period, the establishment of the provinces, or *han*, each with its own lord who blocked open communication with rival *han*, helped to sustain regional differences. On the other hand, the *samurai*, who served as the military officers for the lords, were educated through manuals that emphasized the dialect of the capital city. It was not until the Meiji period (1867) that the notion of a Japanese standard (*hyojungo*) emerged. The Meiji rulers, through national education programs, promoted this standard, based mainly on one of the Tokyo dialects (*Yamanote*) that was heavily influenced by the eastern dialect. This composite is known as *Kyotsugo*. Even with a century of standardization, and with extensive radio and television, Japanese linguists report that people who speak some *hogen*, while they can understand *Kyotsugo*, cannot themselves speak it. Their dialect is hardly comprehensible to *Yamanote* speakers. The political organization of the Japanese state created conditions so that young students from the regions would want to use *Kyotsugo* and deemphasize their reliance on their *hogen*. Japan's nation-state was therefore, at least in part, created politically; the idea that Japan enjoyed a natural condition of linguistic homogeneity is historically suspect.

1.4 Switzerland as a Multilingual State

Language rationalization did not occur in Switzerland, which remains a multilingual state. Four languages—German, French, Italian, and Romansch—all have official status in the Swiss confederation. The key to understanding Swiss language politics is that rationalization occurred not at the political center but at the cantonal level.

Swiss national identity developed over centuries, and did so without need for a common language. From the origins of the Swiss confederation in the late-thirteenth century through the end of the eighteenth century, German was Switerzland's sole official language. In the sixteenth century, the confederation expanded into French- and Italian-speaking areas. The collapse of the confederation during the French Revolution and the installation by the French of the Helvetic Republic, led to the formal recognition of French and Italian. With the fall of Napoleon, however, German again became Switzerland's sole official language. Civil war erupted in the early 1820s, only to yield peace in 1848, in which German, French, and Italian were all accepted as national languages. In 1938, a constitutional amendment declared Romansch as the fourth national language, but it did not receive the same full rights as the other three Swiss languages. Despite societal multilingualism and a history of some language conflict, the imagined community of Switzerland developed without homogenization of the mother tongues.

Yet notions of a common Swiss culture are built upon clear notions of cantonal autonomy. Each canton is permitted to set its own language policies, and the cantons have been strong rationalizers. In 1970, 96 percent of the German Swiss lived in the German region; 92 percent of the French Swiss in the French region; and 79 percent of the Italian Swiss in the Italian region. It is extremely difficult for Swiss citizens living outside their language region to get an accredited education (public or private) through the medium of their mother tongues. Therefore migration of people across language zones has been minimal for centuries.

The rationalization of language at the cantonal level is so important to Swiss national consciousness that language is one of the few areas in which the central government supports welfare redistributions. Because the Italian and Romansch areas do not have the resources to invest in higher education and television in their languages, annual subsidies have been sent to these cantons to help authorities defend their languages.

The case of Switzerland demonstrates that rationalization of language is not a necessary condition for the creation of a nation-state; but it demonstrates as well how important language rationalization is to rulers, even in a country that has accepted its own language diversity.

2. Immigration and Language Rationalization

Nationalism, the ideology behind movements to build nations out of the diverse populations within states or to create states to coincide with nations, has often been suspicious of mass immigration (see *Migrants and Migration*), which might threaten the cultural uniformity of the imagined community. Yet massive immigration has, with very few exceptions, led to intergenerational assimilation into the national language. This is so because immigrants leave their home areas—often escaping from poverty or persecution—in order to make a better life for themselves and their families than they could do in their own communities. Except in rare instances when an entire community uproots itself seeking to preserve its lifestyle in another country (for example, the Amish in the USA), each immigrant family finds itself in its new society seeking scarce jobs and limited opportunities. While each immigrant may want to preserve the language and culture of his/her home area, it would be better for him/her if some other immigrant family organized special schools and organized a supply of sufficient reading material to support the

654

language. If every family is better off relying on someone else to help preserve the language, a 'collective action' problem ensues. The likelihood that the preservational activity will be organized is therefore low. Immigration, then, is rarely a threat to the national unity of the host country.

Research on immigrants to the USA, European states, India, and Japan all shows that the degree of love any group has or its own language can only marginally affect the timing of intergenerational shift from monolingualism in the language of origin to monolingualism in the language of the new home. In some cases, where the immigrant group fears it might be deported (southern Indians in North India), or where the immigrant group speaks the language of the political center but not of the region of migration (Andalusians in Catalonia; Russians in Estonia), evidence shows language assimilation to be much less likely. Since the 1960s, there have been political movements in immigrant communities to use the power of the state to help immigrant communities retain their mother tongues. These movements are most often led not by the immigrants themselves but by second- and third-generation citizens who seek to solidify a political bond with their own people by generating support for a popular issue. These efforts will help support 'assimilated bilingualism,' where the descendants of immigrants retain competence, albeit limited, in their language of ethnic origin, but they will not stem the general tide of language assimilation.

3. Language Revivals

Rationalization from the political center is sometimes countered by revival movements from the periphery. These movements are extremely easy to get going, in large part because language is such an emotional issue. Yet they are difficult to sustain, because while people may vote for the revival of a language in desuetude, they may not like the idea of having their own children educated in it. It is a safer investment most of the time to educate one's children in the language of opportunity rather than in a language that is considered by the descendants of its core speech community to be one of folklore but not science.

In modern European states strong revival movements have occurred in those regions where there was more economic growth in the region than in the political center. Under these conditions, an alliance could form between cultural elites who always wanted to preserve the language and the regional bourgeoisie that was interested more in international business contacts than national ones.

Successful revival movements in regions of contemporary states include Catalan in Spain, Flemish in Belgium, Kannada in India, Estonian in the former Soviet Union, and French in Canada.

Successful revival movements in countries that overcame colonial rule to become independent countries include Somali in Somalia, Hebrew in Israel, and Finnish in Finland. Unsuccessful revival movements include the Celtic languages in the UK, Alsatian and the d'Oc languages in France, Maithili in India, and the indigenous languages in most newly independent African countries. A particularly long and involved revival movement supporting Landsmål in Norway had mixed results.

The successful revival movements teach us that apparently stable nation-states need not remain officially monolingual. Like Switzerland, countries can develop bases other than language to imagine themselves a community. Yet these revival movements also show us that when rationalization weakens at the center, the pressure for uniformity becomes even stronger in the region. Proposed language laws in Quebec, Catalonia, and Karnataka (where Kannada is the official language) have been far harsher in demanding uniformity than were usually the case in the states from which these regions sought autonomy.

4. Late Development and Stable Multilingualism

In states whose boundaries were settled before the nineteenth century, language rationalization was the norm. Here France, the UK, Spain, Sweden, Japan, and China are the principal examples. In Germany and Italy, following the successful nation-state models of their neighbors, nationalism meant political unification to make the language-based nation and the state commensurate. The ideology of the nation-state was so powerful that the breakup of the Austro-Hungarian empire was organized largely along linguistic lines. Nearly all states in Europe after World War I (except for Switzerland and Russia/Soviet Union) were, at least until language revival movements arose, officially monolingual.

4.1 The Former Soviet Union as a Multilingual State

European Russia might have broken up into monolingual states like Austro-Hungarian empire if it too had lost the war. But the Soviet government was able, until 1991, to retain control over a state with over 100 languages. Like France and Spain, the former Soviet Union achieved a remarkable degree of rationalization, with high percentages of the population of all regions having become competent Russian speakers. The business of central rule could take place entirely through the medium of Russian. But like Switzerland, there were 14 Union Republics outside of the Russian Republic, each with its own official language. The 'titular' nationals who are the majority population in these republics have instituted language rationalization programs. Among the citizens who speak former Union Republics languages, there was considerable resistance to the learning of

Russian. Whether there exists an imagined community among these now-independent republics that can override language differences remains to be seen.

4.2 Rationalization in Settler Colonies

In the settler colonies of Australia, New Zealand, and North and South America, the language of the settlers dominated the language of the autochthonous populations, who were excluded from political representation in the period of state formation. Only in the case of Paraguay has an autochthonous language (Guarani) taken on an important official role. There have been language revival movements elsewhere, but none with any important success. The settler colonies followed the pattern of early developers.

4.3 The Postcolonial Multilingual State

Countries that achieved political independence after World War II have established a new norm, that of the multilingual state. Two factors account for the establishment of the norm of multilingualism for the postcolonial states. First, by the twentieth century, an essential part of the business of rule was to provide public education to all citizens. Heads of state were no longer just interested in efficient extraction of taxes or in the basic provision of infrastructure (e.g., roads and irrigation systems). A highly literate population became associated with economic growth and political power. Ministers of education in multilingual societies recognized the near impossibility of providing literacy in a single language, and they pressed for the state recognition of language diversity.

A second factor which helped sustain multilingualism in these late-developing states has to do with the colonial experience. Countries in Africa and Asia had, under colonial rule, modern bureaucracies before they had political independence. These bureaucracies operated in the colonial language. Students from the colony who were able to learn the colonial language got positions of power and prestige in large part due to their language competence. Once these countries received independence, these bureaucrats were essential to implement the policies of the new nationalist leaders. Yet they had an interest in maintaining the colonial language as the language of administration and higher education. Leading bureaucrats overemphasize the difficulties and political inequalities that would result from the choice of an indigenous language as the sole official language of government. This bureaucratic pressure has made the choice of a single official language quite difficult. A standard compromise has been to rely on the colonial language as *official*, but to elevate one or more indigenous languages as *national*, and to have them play a symbolic role in political life.

4.4 India and the 3 ± 1 Language Outcome

India is a postcolonial multilingual state that is not moving toward rationalization or to linguistic uniformity. During its independence struggle, the Congress Party leaders assumed that upon achieving independence, some form of Hindi should be India's official language. But the Indian Administrative Service and other bureaucratic agencies operated entirely in English, the language of colonial rule. Officials in these agencies had a strong interest in preserving English as the language of administration. Although the Indian constitution called for the imposition of Hindi as the All-Union language 15 years after independence, opposition from bureaucrats and from citizens in non-Hindi-speaking areas indefinitely delayed the change. Consequently, there are now two All-Union languages, each of which can be used for official dealings within the Indian state.

Meanwhile, during the 1950s, citizen pressures at the regional levels compelled the government to redraw federal boundaries consistent with language zones. Each state has an official language today, and most of them are zealously pursuing language rationalization policies within their states. By one official measure, as of 1980, only 2.7 percent of the Indian population has as its primary language a language different from the official language of their state. The Indian constitution, however, assures all minorities the right to an education in their own language.

India thus has a multilingual state in which citizens who wish to have a broad range of mobility opportunities must learn 3 ± 1 languages. English and Hindi are necessary languages for a communicating with the central state. It is necessary as well to speak the language of the state in which you live. This makes for a 3 language outcome. A citizen of Tamil Nadu must learn English, Hindi, and Tamil to be able to operate in a wide range of activities within India.

Those citizens who live in states where Hindi or English is the official language need learn only $3 - 1$ or 2 languages. Citizens who are language minorities in some states (e.g., Marathi speakers in Karnataka) must learn $3 + 1$ languages: Hindi, English, Marathi, and Kannada. Thus, there is a range from 2 to 4 (i.e., 3 ± 1) languages that citizens must know. The result has become accepted by most groups in India, and therefore it is probable that India will remain a multilingual state.

4.5 Other Postcolonial States

Many other postcolonial countries, including Nigeria, Kenya, and the Philippines, may follow India's track, with a colonial and an indigenous language sharing central stage in the business of rule. In others, such as Algeria and Zimbabwe, the colonial language will remain as a lingua franca,

but not at the expense of the continued official reliance on indigenous languages, at least on the regional level. Some post-colonial states, such as Indonesia, Cambodia, Malaysia, Tanzania, and Somalia, are on the road toward rationalization. The situation in these countries remains fluid and merits continued observation.

5. Political Implications of State Multilingualism

Throughout this discussion state multilingualism was considered as an outcome of social, economic, and political processes. Political scientists and sociologists have also studied multilingualism as a causal factor explaining political and economic outcomes. This research is not fully developed, and clear patterns have not been specified.

5.1 Multilingual States and Economic Growth

Simple correlational studies have shown that multilingual states are less advanced economically than linguistically unified states. However, these correlations are spurious, because so many early developers have become linguistically unified and so many late developers are multilingual. The causal variable here seems to be timing of development rather than level of multilingualism. It is known that multilingualism is not a barrier to economic dynamism, as can be seen in from Switzerland. But the precise role of language diversity for economic dynamism remains to be specified.

5.2 Multilingual States and Democracy

Political science approaches to democratic theory originally emphasized the importance of language uniformity for democratic stability. It was thought that because democracy requires public participation in open debate this would be difficult to sustain when citizens are unable to communicate effectively with each other. More recent models of democracy, some times termed *consociational*, suggest that decentralized systems, in which each language community has considerable autonomy, are a viable form of democracy. Belgium and Switzerland are used as models for decentralized democracies. Since the 1970s, with the Catalan and Basque languages in post-Franco Spain, and with French in Quebec, it can be seen that while multilingual states may suffer considerable tensions in managing democracies, multilingualism itself does not preclude democratic stability.

While rationalization of language may have some association with democracy, the process of rationalization necessarily entails the curtailment of minority rights. The suppression of Welsh in Britain, of Catalan in Spain, and of Alsatian in France was not done in a democratic spirit. Leaders prompting similar decrees seeking to rationalize Amharic in Ethiopia and Malay in Malaysia have been accused of contravening basic democratic rights of minorities. In twentieth-century state-building, democrats will be compelled to adjust to multilingualism; they will not, in most cases, be able to rationalize language in their states through democratic procedures.

National Language/Official Language
C. M. Eastman

The term 'national language' refers to a language which serves the entire area of a nation rather than a regional or ethnic subdivision. As the language of a political, social, and cultural entity, a national

language also functions as a national symbol (Garvin 1973: 71), recognized as the nation's own. The term may be used to refer to a language indigenous to an area as distinct from one 'brought in from outside' (Ferguson and Heath 1981: 531). The term is also often synonymous with 'standard language.' An 'official language' is a language used for the business of government, a language 'legally prescribed as the language of governmental operations of a given nation' (Ferguson and Heath 1981: 531). The terms 'national language' and 'official language' were included along with others in a 1951 UNESCO publication entitled *The Use of Vernacular Languages in Education* which outlined 10 language situations in the world which planners need to be aware of when making choices as to which languages might be most appropriate for specific purposes such as building nations, doing government business, conducting trade, teaching school, and the like.

Generally, 'standardization' is involved when a language achieves national or official status (see *Standardization*). Standardization is a process 'whereby a particular social dialect comes to be elevated into what is often called a standard or even "national" language' (Fairclough 1989: 56). Standardization is part of the process of unification undertaken by a nationalizing political, cultural, economic entity. A dialect is chosen to be standardized and then it is 'codified' by being written down in a grammar, provided with a dictionary, and accompanied by rules of pronunciation and 'correct' usage so that there will be as little variation as possible in its form. Standard English, so codified in the late 1700s, was read mostly by industrialists and their families, leading one scholar to observe that 'There is an element of schizophrenia about standard English in the sense that it aspires to be (and is certainly portrayed as) a *national language* belonging to all classes and sections of the society, and yet remains in many respects a *class dialect*' (Fairclough 1989: 56). Standard English is a class dialect in that its dominance is associated with class interests and also because 'it is the dominant bloc that makes most use of it, and gains most from it as an asset— as a form of "cultural capital" analogous to capital in the economic sense' (Fairclough 1989: 58).

Throughout the world, various legislative approaches have been taken with regard to making decisions about national and official languages. National languages are important as an aspect of ethnicity as well as of nationality. Issues having to do with media of instruction are inextricably mixed up with what languages function nationally and officially.

1. National/Official Languages and Media of Instruction

For the most part languages designated as 'media of instruction' tend to be those which have been designated as 'official.' It is less common for 'national languages' to also be used in education unless they are also 'languages of wider communication.' Generally, this is a matter of expedience since such languages have more than likely been 'standardized' and there are likely to be teaching materials available in them. Swahili and English are official languages in Kenya and Swahili is the sole national language there. Secondary and tertiary education is available so far only in English. All primary education in state schools is in the process of moving toward Swahili though there continues to be some very early level primary education in other regional languages.

In increasing areas throughout the world English, as a language of wider communication, is gradually being 'nativized.' That is, a number of different world Englishes are developing which function both sentimentally and instrumentally and may well be the future 'national' and 'official' languages of the world. In essence these Englishes, despite curricular and grammatical prescriptions to the country, are the languages of postprimary education in a number of nations. Such 'nonnative' varieties of English occur, for example, in South Asia, Southeast Asia, Africa, the Philippines, and the West Indies (Kachru 1983: 31).

2. People and National and Official Languages

In 1968, Joshua Fishman introduced a distinction between 'nationism' and 'nationalism.' Nationalism is the 'organization of the beliefs, values and behaviors of a nationality with regard to its own self-awareness' (Fasold 1988: 180). It is a matter of group pride regardless of whether the group has political power or territorial strength. Nationism, on the other hand, recognizes that '[L]egislative bodies have to formulate and record laws in some language or languages, children need to be educated through the medium of one or more languages, military and police organizations must function in one or another language' in order for a nation to operate (Fasold 1988: 181). Here political and territorial integrity is paramount. Where this is the case, nationism is best served by an official language or official languages. The interests of nationalism on the other hand are best served by a national language.

> To overstate the case a bit, a national language can be compared to the national flag. A country's flag functions almost entirely as a symbol. An official language is more like the trackage and rolling stock of a national railroad. Its purpose is more pragmatic than symbolic.
>
> (Fasold 1988: 181)

Essentially national languages are associated with sentimental attachments to a nation or a state while official languages make reference to instrumental attachments. That is, national languages are those which make people feel good about their country or

their group while official languages are those which enable people to get things done, to do a job, to earn money, and achieve social status (Kelman 1971: 24–5). Sentimental attachment is seen by some to be more properly a matter of primordial feelings referring to the attachments 'derived from place of birth, kinship relationships, religion, language and social practices' which are natural for them, are spiritual in character, and allow them to feel an affinity with those with whom they share a common background.

People are sentimentally or primordially attached to a political entity when they see it as representative of themselves, they are instrumentally attached to it when they see it as a way to achieve what they want. A national language represents sentimental attachments by blending a need for unity with a need for having a unique language and culture, a national language is a language *of the people*. As the term is used in a nation-building context, it is 'often contrasted with the language of the former colonial overload' (Garvin 1973: 26). In Indonesia, Bahasa Indonesia is a national language while Dutch is a colonial language. The term 'national language' is also used to distinguish a language serving the entire territory encompassed by a nation as distinct from a regional or ethnic subdivision (Garvin 1973: 25). In Latin America this sense is conveyed by the term '*lengua nacional*' while '*lengua indigena*' refers to languages used within the nation in certain regions or by various ethnic groups. In Mexico, Spanish is the *lengua nacional* while Nahuatl is a *lengua indigena*. An official language represents instrumental attachments by providing a way for people to achieve socioeconomic power, an official language is a language *for the people*. Garvin (1973: 25) points out that one defining feature of an official language is that it receives official recognition by a government authority. Further, a national language tends to be also an official language while the converse is not as often the case. In Kenya, for example, Swahili is the national language and an official language while English is another official language.

When choices are made about what will be the national language in a particular nation, considerations regarding the 'need to satisfy these primordial/sentimental needs of unity and spiritual affinity' (Eastman 1983: 34) are paramount. Where there is a common language extending throughout a political entity sentimental and instrumental attachments may be to a single language. Where this is the case that language is usually a standard language.

> The real spread of a standard variety through a population and across domains of use is one aspect of standardization; rhetorical claims made on behalf of the standard variety—that it is the language of the whole people, that everyone uses it, that everyone holds it in high esteem, and so forth—are another. What these

claims amount to is the transmutation of standard languages into mythical *national languages*. A political requirement for creating and sustaining a nation state is that its unifying institutions should have legitimacy among the mass of the people, and winning legitimacy often calls for such rhetoric.

> (Fairclough 1982: 22)

However where this is not the case language conflict may arise.

In 1988, what is known as the Recife Declaration was put forward. In consideration of the Universal Declaration of Human Rights, it focuses on the linguistic rights of groups and individuals and urges the United Nations 'to adopt and implement a Universal Declaration of Linguistic Rights, which would require a reformulation of national and international language policies.' Such a declaration asserts the need to promote the dignity and equity of all languages and an awareness of the need for 'legislation to eliminate linguistic prejudice and discrimination and all forms of linguistic domination, injustice and oppression, in such contexts as services to the public, the place of work, the educational system, the courtroom and the mass media.'

3. Language Legislation

At the same time that linguistic rights have become an issue, there are countervailing forces at work as well such as the adoption of English-only policies in various parts of the United States. Decisions resulting in naming specific languages as national or official have ramifications for such issues.

What is known as the 'Muhlenberg legend' has perpetuated the idea that German almost became the national language of the United States in 1794 losing out by just one vote in the house of Representatives. What took place was that Germans from the state of Virginia asked for some laws to be issued in German as well as English. When it came to a vote this request was defeated 42–41 and it is thought that perhaps one Frederick August Muhlenberg cast the deciding negative ballot (Heath 1981: 9).

The United States has long rejected choosing a national language yet Americans believe that they should be able to read and write a 'correct' form of American English (Heath 1981: 6). It comes as a surprise to many people to learn that the United States does not have a national language in any legal sense of the term and that there are a number of languages which may be used officially in different places. For example both French and English are official in Louisiana and have been for a long time and Hawaian is an official language in Hawaii. Only in recent years have states made laws about restricting official language use to English-only in an effort many see to be to stop the spread of Spanish. These people, such as the noted semanticist and former Senator from California, the late S. I. Hayakawa, feel

that the motivation for working state-by-state toward making English eventually the national and only official language in the US is to ensure that the United States does not become another Canada. This is in reference to the bilingualism there which has a long and involved history of conflict associated with its having achieved legal status. Indeed, the very linguistic diversity that was a characteristic of the early days of the US and the bilingual tradition in schools, churches, banks, and newspapers through the nineteenth century only gave way to a tradition espousing monolingualism in English in the early twentieth century. The current push to revitalize bilingualism along with a simultaneous call for English-only seems 'to tug the future of English in the United States in different directions' (Heath 1981: 7).

Various political entities have statutes specifying a national language and official language(s). Again, in the USA, there are a number of distinct enclaves where Spanish is the main language (Little Havana in Miami, Spanish Harlem in New York City, and barrios in East Los Angeles). Even though these areas are relatively small, 'such limited territoriality can be and has been used to obtain official bilingual status for an ethnic tongue' (Mackey 1983: 183). In 1973, Spanish became official in Miami. In some parts of the world, percentages of population define 'official minority' status with accompanying language rights. In Finland, if a group comprises 6 percent of the population its language may be accorded 'official status.' In the US constitution, all children of US citizens are granted the right to equal opportunity for public education—including those whose home language is other than English. This amounts to what is known as 'individual official bilingualism' in contrast to the Canadian situation of 'institutional and territorial official bilingualism' (Mackey 1983: 184).

It is rather ironic that '[W]ithout either constitutional or subsequent legal declaration or requirement that English is the *Official* (let alone the *National*) *Language*, a complex web of customs, institutions, and programs has long fostered well-nigh exclusive reliance upon English in public life' (Heath 1981: 517) and a concomitant loss of ethnic languages by members of many groups.

In India, a number of Articles of the constitution (Articles 120, 343, and 344) have to do with official language matters. Articles 120, 343, and 344 'deal with the use of Hindi as the official language of the Union in the parliament and for other official purpose' (Dua 1985: 200). These articles provide for a progressive increase in the use of Hindi and a restriction on English such that Hindi will replace English in 15 years as the sole language of the Union (i.e., as the 'national language' of India). Other constitutional provisions provide for a number of regional languages (including Hindi in its region) having official status in state legislatures. There is a provision whereby the President of India may recognize any language as an additional *official* language for specific purposes or in specific areas (Dua 1985: 201). Such recognition is not frequent given that all but 2.7 percent of the country's people have the language of their state as their primary language (Laitin 1989: 420). In the meantime, English is an associate official language according to the Indian constitution (Kachru 1981: 23). It has become apparent that the constitutional efforts to replace English with Hindi may well run into difficulties due to the practical necessity of the Indian High Court having sanctioned regional state policies. In India there is likely to continue to be many national and many official languages.

If it were to happen that another language became official in the USA, such status would entail citizens' rights to use that language and to expect officials to use it in return in interaction with them. As Mackey observed, 'With more than a quarter-million faceless federal bureaucrats answering the public, someone's language rights are bound to be infringed upon sooner or later' (Mackey 1983: 202). In Canada, precisely to safeguard citizens versus the bureaucracy in exactly this situation, the Official Languages Act provides for a Commissioner of Official Languages who answers 'directly to the people through their representatives in Parliament' (Mackey 1983: 202). Part of this commissioner's ombudsman role is to issue annually a report of failures to enforce Canada's official bilingualism. Constitutionally, the USA has the power to create ethnic states which could have their own national as well as official languages so that there might be, for example, a Spanish state or a French state (Mackey 1983: 203). So far states have only opted for making these languages official—including states which have recently passed English-only legislation.

4. The Struggle for Language Rights

Just as the distinction between national and official language may be seen to parallel a distinction between symbolic and functional language attachments, and between nationist and nationalist goals, a parallel may also be seen when it comes to the use of language. The requirements of a national and an official language differ. The best choice of an official language is often that of the former colonial rulers which most likely set up the polity's system of government in that language. Such a colonial linguistic legacy as a new nation is being forged from a colonial past allows for nationist tasks to be 'carried out with the least disruption' (Fasold 1988: 182). This same language, however, 'is an absolutely

atrocious choice as a national language' for '… Nothing could be a worse symbol of a new nation's self-awareness than the language of a country from which it has just achieved independence' (Fasold 1988: 182). However, if the national language of a newly independent nationality is the same language as that of the former colonialists, that language (newly nativized) would work well as both the national and official language of the new nation.

The functional versus symbolic distinction between national and official languages may also be seen clearly when it comes to *bi-* and *multi*-lingualism. Functional bilingualism is served in the USA, for example, by having safety signs on airplanes in both Spanish and English—that is, they 'might actually save lives' (Mackey 1983: 193). Symbolic bilingualism, on the other hand, is served, for example, by having all signs in both Spanish and English even where it makes little difference as on street signs or in monolingual areas. Functional bilingualism is a matter of official language use, while symbolic bilingualism is a matter of national language use.

5. National 'National' Languages

Above, it was noted that national languages are often official as well while official languages are less often national languages. However, there is one sense of the term 'national' language that complicates matters. For some the term applies to what is often thought of as a 'vernacular' language. A vernacular is the first language of a group which has been socially or politically dominated by a group with a different language. For example, in Kenya a very well known author, Ngugi wa Thiong'o, has urged 'that the label *national language* be applied to the languages usually called *vernacular* to maintain the idea that ethnic groups in Kenya are all equal as political, social, and cultural entities and are not dominated by any one group with a different language' (Eastman 1983: 6). This usage is in keeping with the definition of 'national language' mentioned in the introduction above as being indigenous rather than imported. Similarly this usage of the term is in conformity with situation in India where the Union has a national language (Hindi) and two official languages (English and Hindi) and the various states in India each have their own national (regional, indigenous, ethnic) language and various official languages.

In fact in Kenya, opinions have long been expressed that the country needs its own national language based upon the Kimvita dialect of Swahili as spoken in Mombasa, Kenya, rather than adopt the standard form of Swahili based upon the Kiunguja dialect of Zanzibar in Tanzania. Some feel that the relative lack of success Swahili has achieved in Kenya as its national language compared to Tanzania is a matter of Kenyans feeling 'indisposed towards having to give continued preference to forms that

are not their own' (Harries 1983: 128). However, instead it might be that the ideology associated with a national language disfavors indigenous languages in favor of developing localized, nativized, and nationalized versions of colonial official languages in recognition of the need to get the nation built as well as to develop nationalistic feelings.

As should be clear from much of what has been said here, there are practical advantages to choosing former colonial languages to be used for official purposes including the fact that they are commonly languages of wider communication which have developed into international languages as well. In their postcolonial territories they often begin to express the new nationalities that have emerged by nativizing in that new setting. In such a manner:

> Indian English, Jamaican English, Philippine English, Singapore English, Nigerian English etc., have become firmly established on the linguistic map of the world; and like American English they are moving in the direction of becoming a powerful symbol of national identity, which in multilingual and multicultural countries such as India or the countries of Black Africa none of the native languages could ever be.
>
> (Coulmas 1988: 18)

Indeed in sub-Saharan Africa, the official language of most nations is the international language in which the nations were formerly governed; French in French and Belgian colonies; English in British territories, Portuguese in Mozambique and Angola. Yet in the nations where these international languages are official relatively few people outside of urban areas know the languages. Choice of an outside language as official has much to do with its neutrality with regard to internal conflicts and everyone, at least theoretically, has an even chance of access to it. However, it is more often the case that certain ethnic groups in an emerging nation will have had more training by missionaries or the military or even by governing officials prior to independence, and members of the traditional elite, as well, may have had a headstart. Indeed to some extent one may define 'elite' in such a context as 'the select speakers of the official language' (Myers-Scotton 1989: 9). This situation allows such people to maintain their status as members of the elite in opposition to others who may have a different power base and who may well argue for the development of national 'national' languages rather than localized, nativized, or nationalized forms of the international official language.

> As a symbol of their own legitimacy, these proto-elites do not seek to acquire the attributes of the elite, including their language use patterns. Thus, disparities in linguistic repertoire across groups can be seen as an indication of contemporary class conflict. An obvious

place for conflict is between an education-based elite which controls the infra-structure of the public sector and those proto-elite with an economic base.

(Myers-Scotton 1990: 11)

Nationalism and Language

L. Greenfeld

The understanding of the relationship between nationalism and language hinges upon a clear definition and grasp of the nature of nationalism itself. Though the body of literature dealing with this important phenomenon is vast, so far it has not been properly understood, and as a result the connection between it and other phenomena with which it is commonly associated often appears more problematic than it actually is. This article first presents the conventional view of nationalism and its relationship with language, in which language is seen as a determinant of nationality; then proposes an alternative position; describes the context in which the conventional view emerged; and, finally, provides some important examples of the development of national languages and the influence of nationalism on language.

1. The Conventional View of the Relationship

Of all the institutions which mark a common nationality, language is the one of which a people is most conscious and to which it is most fanatically attached. It is the one conspicuous banner of nationality, to be defended against encroachment, as it is the first object of attack on the part of a power aiming to crust out a distinction of nationality among its subject peoples .... With few exceptions the European nationalities are essentially language groups; and [for some of them] language is the admitted criterion of nationality.

(Buck 1916)

This view, expressed in an article published in the *American Political Science Review* during World War I (Buck 1916), remains dominant in regard to the relationship between nationalism and language (see Anderson 1983, Gellner 1983, Smith 1986 for some

662

contemporary expressions). At the root of this view lies the assumption that the world is naturally divided into separate and self-contained nations and that national identity and consciousness emanate irresistibly and without any assistance from objective national endowments—endowments that are necessarily unique to the given nation—which fall into two categories: either 'ethnic' or geopolitical. This assumption, in turn, derives from a misguided definition of nationalism as a modern form of a generic identity, identity as such, a psychological rather than cultural (or symbolic) phenomenon: 'a high degree of psychological coherence,' or 'group unity which has developed in a given aggregate of people,' on the basis of 'objective or substantive conditions,' the 'very real factors of nationality which make for the separateness and identity of various nations, such as 'the sharing of a common language, the occupation of a territorial area which constitutes a natural unit,' common religion, common mores, and common interests (Potter 1975).

The 'ethnic' attributes which are believed to 'generate nationality include physical type, religious and secular traditions, and language (see *Ethnicity and Language*). Of these, language is most regularly referred to. Excessive concentration on physical type is avoided first of all because of its biological—and therefore, potentially racist—connotations, but also because of its empirical ambiguity. Secular traditions are almost as intangible and hard to use as an explanatory variable, while, on the other hand, with five major religions shared by hundreds of officially recognized and aspiring nationalities, religious traditions which can be defined with precision are also entirely unhelpful in explaining national diversity. Language appears not to have such disadvantages and for this reason is frequently regarded as the ethnic determinant of nationality, one's nationality being, as in the quotation above, considered coterminous with one's linguistic group.

Yet there is no one-to-one correspondence between language and nationality, which should necessarily exist if language is the determinant of nationality. Obvious counterexamples are, on the one hand, Switzerland, in which several linguistic groups— French, German, Italian, and Romansch—emphatically claim the same national identity, and on the other hand, the nation of the USA, which shares its language with the UK, from which it dissociated itself in a most dramatic and unambiguous manner. Indeed, so glaring is the contradiction between the experience of the American nation, which happens to be the nation of a great many contemporary students of nationalism, and the prevailing view of the nature of national phenomena, that many are dubious as to the very existence of American nationality. Those who believe in it feel obliged to defend their position in elaborate disquisitions, often apologetic in tone.

To assert that the American nation is a nation like all other nations is an act of intellectual audacity.

Some abandon the futile attempts to fit cases conspicuously inconsistent with the theory into its framework, and see nationality as determined by geopolitical factors rather than by 'ethnicity.' This, however, does not solve the problem: the relationship between state-formation, centralization, and even territory, on the one hand, and national identity, on the other, is as inconsistent as that between nationality and language, and there is as little evidence to support an emanationist theory of the geopolitical variety, as that of the ethnic or specifically linguistic sort.

2. The Nature of Nationalism

Nationalism is a cultural, not psychological, phenomenon. Like many other stimuli, it arouses psychological responses, and therefore has psychological manifestations. But its specificity (what makes it what it is and distinct from other forms of identity) lies not in the specificity of responses aroused—which, in fact, are not specific to it—but in the specificity of the symbolic stimulus. A nation is not 'a body of people who feel themselves to be one,' it is a collectivity defined and seen (a collectivity the very essence of which consists in the way it is defined and seen) by its articulate members as one in which every member is fundamentally equal to any other. In fact, there are no objective foundations for nationality. Empirical study reveals that all nations—as nations—are artificial constructions. Nationality is not natural. Every social group has an identity, but nationality is not any identity, national identity is an identity of a particular kind and its development in any given society is not socially, biologically, or otherwise imperative. Instead it is in every case a product of an historically distinctive situation. The only foundation of nationalism as such is an idea, it is a particular perspective, or a style of thought. The specificity of national—as opposed to other—identities consists in that these identities derive from membership in a 'people,' a mass of somehow bounded population, whose boundaries and nature are defined in various ways, but which is always perceived as larger than any concrete community, and as fundamentally homogeneous and only superficially divided by status, class, or locality.

It is significant that the word *people* came into its modern use with the emergence of national identities. As a synonym of the 'nation,' it acquired the meaning of the supreme object of loyalty, the bearer of sovereignty, and the basis of political solidarity—and lost its previously common meaning of 'rabble.' The meaning of the word *nation* when this happened was that of 'an elite of representatives.' This, a result of a long history of semantic permutations, was the legacy of medieval church councils where representatives of

various ecclesiastical and secular potentates were referred to as 'nations' (Zernatto 1944). In this meaning of 'an elite' the word *nation* was applied, in England, in the sixteenth century to the population of the country. The equation of the two concepts ('people' and 'nation') in fact signified the symbolic elevation of the populace to the position of an elite, and reflected a tremendous change of attitude; it meant that, for some reason, members of all orders, including the highest, wished to identify with a group from which earlier they in no uncertain terms strived to dissociate themselves. The word *nationalism*, which was first used at the end of the eighteenth century, when several societies were simultaneously in the process of conversion to national identity, is an umbrella term for this new attitude. It refers to the novel political and cultural discourse which asserts this principle (of identification with the 'people') as the basis of national identity.

The birth of nationalism was the breakthrough to democracy, and cannot be understood apart from this political meaning. As nationalism spread, the original equivalence between it and what came to be called 'values of the democratic society' was lost, but it still connotes the new, fundamentally leveling, populist, or demotic, attitude. This derivation of identity from membership in a large and essentially uniform population, is common to all nationalisms that have been emerging since the process first started. Apart from this perception of the source of identity, as the vast literature on the subject attests, different nationalisms share little. The national populations—variously titled *peoples, nations*, and *nationalities*—are defined in many ways, and the criteria of membership in them vary. This variation is the source of the protean nature of nationalism and the difficulty, even the impossibility to define nationalism by reference to any of the attributes frequently associated with it. Only the subscription to the same principle of identity justifies treating all these varieties as instances of the same general phenomenon. At the same time, derivation of identity from membership in a people distinguishes nationality from other types of identities. In this national identity differs from religious identity, for the latter derives from the transcendental beliefs of the individual, of which membership in a religious community is, essentially, a result. And since the notion of 'people' cuts across divisions of class and locality, and is, however stratified in fact, perceived as fundamentally homogeneous, and the divisions are perceived as having secondary importance, national identity also differs from class, estate, and local identities which emphasize these divisions as essential.

The only generalization possible regarding the emergence of nationalism in different societies is that the incentive for its creation or adoption is invariably provided by the structural condition of 'anomie'— the lack of correspondence between the traditional definition of the social order and the involved agents' place in it, on the one hand, and the changing reality, on the other. This anomie may, but need not, affect the society at large; it does, however, affect the relevant agents (the architects of the national consciousness) directly. These agents are different in different cases, and the anomie is expressed and experienced differently, but frequently it takes the form of a crisis of identity and/or acute status-inconsistency.

Nationalism as a new way of relating to the world emerged in medieval Europe. In all other cases the basic idea was adopted, not created anew. Because of the dominance first of Europe, and then the West as a whole, this style of thought soon became the canon. As the sphere of influence of the West expanded, societies entering it had in fact no choice but to become nations. At the same time every specific nationalism is an indigenous development. It is never imported wholesale, but is modified in accordance with the character and situations faced by every importing group. Every specific nationalism is the end result of these modifications. That is why, while nationalism everywhere has a certain equalizing influence on social life, and changes at least the form of the political discourse and procedure in the direction of democratization, different nationalisms affect the respective societies harboring them in fundamentally different ways.

National, as any other, identity frequently utilized the available primordial or 'ethnic' characteristics of a population, such as language, which contributed to its sense of uniqueness. Yet it should be realized that such characteristics in themselves do not constitute an identity, but represent elements which can be organized and rendered meaningful in various ways, thus becoming parts of any number of identities. The possession of an identity and a sense of uniqueness, however formed, in turn in no way necessitate the emergence of a national identity. As much as language, these are universal attributes of human groupings; in distinction, national identity is an historically circumscribed, modern phenomenon, and cannot be explained by its association with such universal attributes. Any one ethnic element serves as the raw material for the national identity only if interpreted as an element of nationality, namely when the principle of nationalism is applied to and bestows on it a new significance.

3. The Origin of the View of Language as the Determinant of Nationality

The idea of language as the determinant of nationality, then, is a myth, and as any myth it reveals more about what its creators sought to see in reality than about what there was to see. In general, the notion of

nationality as a sense or a fact of objective identity, based on objective attributes of a people, whether ethnic or geopolitical, is not a result of empirical study, but of an uncritical acceptance of the European, specifically German, view of nationality, developed by early nationalists and perpetuated in historical scholarship and theories of various social sciences, deeply influenced by German academic traditions. The idea of language as the expression of a people's uniqueness and the basis of national consciousness and identity has its roots in Pietism, a religious tradition which represented a profound formative influence on German nationalism and a movement with a wide appeal and numerous converts within every class of society (see Pinson 1934). Pietism was a variant of religious mysticism which became a widespread phenomenon in Germany after the Thirty Years War and was a response to the misery caused by it. Under its proper name the movement emerged in 1675. An outgrowth of the Protestant Reformation, it was opposed to the established orthodoxy, and represented the adaptation of the dogma to the aspirations, situations, and constraints of the population that adopted it. As mysticism in general, Pietism was a by-product of the attempt to use the official religion (in this case Lutheranism) as a practical philosophy: the means of rendering the existing order of things, in which suffering was the main element, both meaningful and livable. It was a religious ideology of a static society, whose members were unacquainted with worldly success, but intimate with hardship and disaster, which in the form of disease or poverty seemed always to wait around the corner, and which thus fostered a fatalistic outlook. Powerless to change their condition, Pietists interpreted it as a sign of grace. Their misery itself, the 'humility and abnegation' which most of them could not escape if they tried, became a proof of '*certitudo salutis*,' and was freely chosen.

The immediate knowledge of salvation manifest in misery not only led to passive acquiescence with fate, but was actively sought. Election could be proven by active piety and by emotional experience of unity with Christ. Emotionalism was the central characteristic of Pietism, and its counterpart was scorn for doctrine and theological learning, for these did not contain the certainty of salvation. A logical consequence of the de-emphasis of dogma and the view of religion as a personal unity with God was broad tolerance of the forms of Christian worship. Theoretically at least, all forms were legitimate, so long as the faith was sincere, idiosyncracy being in fact a sign of naturalness, sincerity of faith. The counterpart of this position on a collective level was a new respect for the forms of worship characteristic of ethnic communities (of Christians), and a novel, mystical idea of native language, the vernacular which, in

Protestantism, replaced Latin as the medium of worship. Ethnic communities were unique, peculiar expressions of God's love and wisdom. Therefore, it was a matter of Christian piety to preserve one's uniqueness. The mother tongue, in particular, acquired the dignity of the channel through which God manifested himself to a people, the peculiar, individualized link between the deity and a specific community. It was thus sanctioned and acquired value beyond instrumental utility. This mystical idea of language as a peculiar bond with God first appeared in the thought of Jacob Boehme.

The central notions of Pietism were appropriated and secularized by Romanticism, which was thus able to perpetuate them in the age which was becoming increasingly indifferent to religion. The architects of German nationalism were Romantics, and it was through Romanticism that Pietism exercised its most potent influence on German national consciousness. For the nationalists 'of Pietist formation,' who no longer believed in God, uniqueness retained its ultimate value. The innermost unique character of a nation—its individuality—was faithfully reflected in its language, and the German tongue, it was claimed, differed from the rest in that it was not contaminated by borrowings from other languages, but remained pure. In Fichte's words, it was the *Ursprache*, the original language. In the early nineteenth century German language became an object of worship. It was a favorite theme of patriotic poetry. Arndt's *Des Deutschen Vaterland*, one of the most popular examples of such poetry, defined Germany as the realm of the German language. 'Turnvater' Jahn, whose zeal for the perfectly German body did not blind him to the importance of its spirit, but whose obsession with the necessity to combat foreignisms in the German language cast doubt on the much advertized purity of the latter, proclaimed in *Das Deutsche Volkstum*: 'A people is first made into a nation by its mother-tongue,' and called on the State to use the knowledge of German as a qualification for citizenship. In the mind of the creators of the German national consciousness, however, the language, deeply revered as it was, was but an epiphenomenon, a reflection of race, 'the indisputable testimony of common descent.'

German was not the only language to be praised for its purity. Already in the fifteenth century, at least three centuries before the advent of national consciousness in France, but when the sense of a uniquely French (not national) identity was already developed in certain circles, French was similarly belauded. An admirer, Jean de Montreuil, though writing in Latin, extolled its merits as superior to other European languages of note, specifically German and English. The reason for such superiority, thought Montreuil, was the purity and originality of French, in the sense that it remained true to its

665

origins and was impervious to foreign influences which corrupted the other two tongues (see Beaune 1985). Quite apart from the fact that the purity of French, as that of German, was presumed irrespective of evidence, in the French case, clearly, the notion of the purity of the native language in no way contributed to the development of a national sentiment. It did have this effect in the case of German nationalism, because its creators were intellectuals for whom the language was the working tool and whose area of influence extended throughout its domain. It was in their interest to downplay the importance of political boundaries which divided this domain into a multitude of independent principalities, and to define the nation as a linguistic unity. The alleged characteristics of the language in this case became the characteristics of the nation.

4. The Construction of an 'Ancestral' Language

The history of the ascendancy of French deserves consideration, for it provides a particularly telling example of the historically contingent nature of the 'national' language. The French language was not originally the language of France. It was 'the French of Paris,' where indeed it was spoken. Its origin was *'francien,'* the dialect of *'Francie,'* the territory between Somme and Loire, which is the tenth and eleventh centuries constituted the domain of the Counts of Paris, the progenitors of Capetian kings. It was neither spoken nor, apparently, for a long time written in the other parts of France. The literary production in the vernacular was predominantly Anglo-Norman in the eleventh and twelfth centuries, and Picard, Champenois, Bourguignon in the thirteenth to fifteenth centuries, depending on the province and native dialect of the authors (Citron 1987).

The linguistic policy of the Crown was not forceful. While Philip the Fair made French the language of royal edicts in the northern parts of France, in the south the administration still used Latin. Two hundred and fifty years later the Edict of Villers-Cotterets of 1539, under Francis I, extended the use of French to all official deeds. But yet another century had to pass before a Bourbon, Louis XIII, decreed in Code Michaud of 1629 its compulsory use in the registration of baptisms, marriages, and burials.

Throughout the Middle Ages the population of France was divided into at least five linguistic groups (the speakers of *langue d'oil, langue d'oc,* Basque, Breton, and Flamand, some of which were further subdivided into important dialects). This evident lack of linguistic unity, namely the conspicuous absence of the French language, was, paradoxically, a matter of pride rather than mortification for linguistic patriots; it was believed to be a reflection of the imposing size of the kingdom, which compared so favorably to

that, for example, of the pitifully small England that could boast but one native tongue. The situation, moreover, in no way prevented the presentation and laudation of the French of Paris as the French language which, beginning with the fourteenth century, and in the atmosphere of the growing appreciation for 'mother' tongues in general, became an object of ardent love among scholars and men of letters—the creators of symbols of collective identity—and as a result, a central symbol of the French identity, and eventually an objective characteristic of the French ethnicity. In many parts of France, however, it was not spoken as late as the second half of the nineteenth century (Weber 1976).

The example of France, one of the paradigmatic early nations, underscores the weakness of the theory which views national identity as a reflection of an objective unity and separateness based on primordial, 'ancestral' ethnic characteristics, and specifically on language. For instance, it is clear that there is no more reason to consider French an ancestral, or native language of the French people, than to regard English as the ancestral language of Americans of non-English origins. A national language is not an inherent attribute of a given nation, rather it is claimed and interpreted as such.

5. The Influence of Nationalism on the Development of Language

While language cannot be considered as a cause of the emergence of nationalism, nationalism in many cases stimulated and directed the development of language. The influence of nationalism on language is evident, first, in the changes in vocabulary, which reflected the replacement of whatever identity the collectivity in question had previously by national identity, and the transformation of the referent of collective loyalty.

For example, the emergence of nationalism in sixteenth century England (the first crucial case of nationalism), was accompanied by the change in political discourse, clearly discernible in Parliamentary papers, and recorded in the dictionaries of the period. Between 1500 and 1650 several crucial concepts altered their meaning and came into general use. Among these concepts were 'country,' 'commonwealth,' 'empire,' and 'nation.' Somewhat later to these was added the concept of the 'state.' Previously defined as 'an elite of representatives,' the word *nation* was now applied to the people of England. The word *country,* the original meaning of which was 'county,' a locality and an administrative unit, already by the 1530s acquired the sense of 'patria,' and became increasingly used as a synonym of the word *nation.* Both *country* and *nation,* therefore, became synonymous with the word *people,* which changed its meaning accordingly. In a 1499 dictionary it could still be found only in

conjunction with *common*, and *common people* meant 'plebs.' The concept *empire*, which in medieval political thought referred to the attribute of kingship and denoted supreme authority in temporal matters, lost its medieval connotations and already in the first half of the sixteenth century, due to no small extent to the separation from Rome, was increasingly understood to mean a 'sovereign polity.' It is in this sense that England was referred to at the time as an empire. The word *commonwealth*, the exact English rendition of '*res publica*,' gradually exchanged its meaning of the 'public good' or 'common well-being'—the sense in which it was commonly employed at the very beginning of the sixteenth century—for that of a 'society' and also became interchangeable with *country* and *nation*. The term *state*, was a slightly later addition to the vocabulary and, like *empire*, remained less evocative than the other new concepts. Its initial meaning was that of an 'estate' or 'domain' (specifically, the royal estate). Towards the end of the sixteenth century it acquired the meaning similar to that of *country, commonwealth*, and *nation*.

Similar changes can be observed in other emergent nations (namely, in societies in the process of substituting a national identity for the forms that preceded it). For France, where nationalism emerged in the course of the eighteenth century, some quantitative indicators of this change of sentiment and vocabulary are available. According to a limited but representative sample of the University of Chicago ARTFL database of French literature, between 1710 and 1720, and then again between 1750 and 1760 there occurred a significant increase in the employment of the related concepts *nation, peuple, patrie, and état*, which signified the transfer of loyalty to the community (from the person of the king) and nationalization of discourse. Between 1700 and 1710, the word *nation* was used in the literature only 45 times in 7 volumes out of the corpus of 20. In the next decade it was employed 106 times, in 12 volumes out of 25. Its use steadily increased, going up sharply between 1751 and 1760, when it appeared in 990 instances in 43 out of 95 volumes, and thereafter remaining on this high level. The word *peuple*, which was used 376 times between 1701 and 1710 in 12 volumes, in the next decade appeared 1782 times in 19 texts, and after 1760 became even more frequent. The word *patrie* jumped from the low of 34 instances (used sparsely in 12 texts) per decade (1701–10) to 279 in 14 texts between 1711–20; between 1751–60 it appeared 462 times, being employed in 48 volumes; there were 658 instances (in 61 texts) between 1761–70, and 806 (in 40 volumes) between 1781–90. A similar increase can be observed in the use of the word *état*, although in this case, due to the multiple meanings of the word, plain numbers are less helpful. The meanings

of these core concepts changed accordingly. For example, in the dictionaries of the beginning of the century, the word *peuple* was ascribed two meanings, the general one—the sum of individuals inhabiting one country—and the particular meaning defined by opposition to the nobility, the wealthy, and the educated, that is 'plebs.' In the academic dictionary of 1777, the emphasis had changed dramatically: the general, previously neutral, meaning of the word became unmistakably positive, while the particular, derogatory sense, which was stressed in earlier dictionaries, all but disappeared. Both the explicit definition and the examples offered made the 'people' an eminently respectable entity, constituted by laws more than by anything else and the source of truth.

More important than the generation of political vocabulary was the stimulation of the development of general potentialities and expressive capacities of the language provided by nationalism. The burgeoning and triumphant English nationalism of the Elizabethan period, for instance, is chiefly responsible for the remarkable efflorescence of the English language and secular vernacular literature which laid the foundations of modern English culture. Those who contributed to this surge of cultural creativity were fully aware that it was unprecedented and sudden, and that before their time there was little to speak of in the field of English letters. Indeed, the early English authors on whom lavish praise was showered were only three—sic!—in number: Chaucer, Gower, and Lydgate. The rules of English grammar were not yet fixed, and spelling itself, as the sources amply demonstrate, was inconsistent and shifting. The Elizabethan nationalist writers saw themselves as founders of the national culture. 'We Beginners,' wrote Gabriel Harvey to Spenser:

> haue the start and aduantage of our Followers, who are to frame and conforme both their Examples and Precepts, according to that President which they haue of vs: as no doubt Homer or some other in Greek, and Ennius or I know not who else in Latine, did preiudice, and ouer-rule those, that followed them ....

Yet, the unformed English tongue was an object of passionate devotion. It was loved as 'our mother tongue,' and cultivated for what it could contribute to the nation's standing—as its 'best glory.' The consummate expression of English linguistic patriotism of the period was Richard Carew's *Epistle on the Excellency of the English Tongue* (1595–96), which he wrote with an intention to prove the equality of English to the more developed languages of the time, 'seekinge out with what Commendations I may attire our english language, as Stephanus hath done for the French and diuers others for theirs.'

667

Rather than being sparked by language, nationalism led the patriots to focus attention on it, stimulating its systematization and development. It was patriotism, rather than the actual merits of English at the time, which led Samuel Daniel to muse in the 'Musophilus' about the great role it was destined to play:

> And who, in time, knows whither we may vent
> The treasure of our tongue, to what strange shores
> This gaine of our best glory shall be sent
> T'inrich vnknown Nationes with our stores?
> What words in th'yet vnformed Occident
> May come refined with th'accents that are ours?

But this wishful thinking eventually made English great and established it as the foremost language in the world.

Another celebrated language, the one in which some of the finest literature of all ages was written, Russian, was virtually created by nationalism. Russian national consciousness—and Russia as a nation—was born during the reign of Peter the Great (1682–1725) and to a large extent its creation was due to the aspirations and policies of this extraordinary ruler. In the beginning of his reign at the close of the seventeenth century Russia had two languages: the written Church Slavonic, remote from everyday life and intelligible only to a chosen few, and the chiefly spoken language of the mundane—Russian. Both were inadequate for the expression of the new political and social reality; so much so that at some point Peter wanted to make Dutch the official language of his state. Having, apparently, to give up this idea, the great tzar, in 1700, introduced a new, secular type (*grazhdanskaia azbuka*) and thus laid the foundations for modern literary Russian. His decrees and the writings of his close collaborators offer a glimpse into the process of forced, active formation of the new vocabulary: these documents are interspersed with foreign words with Russian endings, and their explanations in parentheses or on the margins.

For at least half a century the infant language, devoid of any agreed-upon orthography and limited in vocabulary, lingered waiting for proper direction. But toward the 1750s it became the focus of attention and devotion of non-noble intellectuals—the first group of Russian men of letters—for whom its successful development was a matter of personal honor. This group was also the first one in Russia which could be characterized as nationalist. The precocious nationalism of the non-noble intelligentsia, which manifested itself in the middle decades of the eighteenth century (1730s–1760s) was all the more remarkable because of the singular ethnic profile of this group. It is possible that as much as 50 percent of this first mass of Russian nationalists were Ukrainians. This fact merits mentioning in the context of

the 1990s and adds more than a touch of irony to it, especially since these were also the creators of the Russian language.

The non-noble intellectuals were placed in a structurally imbalanced situation. Like so many other elements of modern Russian society, this intelligentsia was created by Peter the Great from scratch, for before his time there were no secular schools in the country, and all its educational needs had to be satisfied by theological seminaries. The intellectuals represented a new stratum and none of the existing definitions fit them. They needed a new perspective, a new identity, that would confirm the sense of personal worth they acquired with their education, justify their aspirations, and condemn the arrangements which left them unfulfilled. The demotic idea of the nation could answer their needs, and they turned patriots. The intellectual pursuits of this group were motivated by the desire to aggrandize Russian culture and make it comparable to the cultures of Western Europe. The efforts to develop the Russian language attested to this preoccupation most tellingly.

The ultimate expression of eighteenth-century Russian linguistic nationalism is found in the 1755 *Russian Grammar*, written by the greatest luminary of the period—Russia's first grammarian, who was also its first chemist, physicist, historian, and significant poet—'this Pindar, Cicero, and Virgil, glory of Russians,' Lomonosov. In Russian, he wrote, was found:

> the majesty of Spanish, the vivacity of French, the firmness of German, the delicacy of Italian, and the richness and concise imagery of Greek and Latin ....
> And if something should be found incapable of expression, the fault is not that of the language, but of our own capacity.

At the time when he wrote this, it must be emphasized, the Russian language practically did not exist. The lesser members of the intelligentsia, however, spared no effort to make Russian conform to this exalted image. A Ukrainian Samoilovich urged the creation of a Russian medical vocabulary, 'terms which are not even known in Russian'; at the same time, rather inconsistently with the recognition of the paucity of the language which this implied, he stressed the beauty and richness of Russian and quoted Lomonosov. Another Ukrainian, also a doctor, Maximovich-Ambodic 'like a bee' collected Russian words which could be used in medicine. A 'native Russian' K. I. Schepin, the first Russian professor of medicine, resolutely lectured in Russian, though, as he confessed, 'to deliver ten lectures in Latin is easier than one in Russian.' Still another Ukrainian, Poletika, compiled a comparative dictionary in six languages, juxtaposing Russian with

the tongues 'considered most famous and necessary for the sciences.' The intellectuals' awareness of the pioneering nature of their efforts and the newness of the language they tried to develop went hand in hand with an immense pride in it and an unshakable belief in its colossal potential. In 1773, Svetov, the author of *Study in the New Russian Orthography*, called the language he and his associates were forging 'the new-Russian [*novorossiiski*] language' and dated it back only to the 1750s and 1760s. However, at the same time another member of the group, Popovskii, confidently asserted:

> the age of philosophy did not end with Rome: it will not refuse to talk to all nations of the following ages in their languages .... As to the abundance of the Russian language, in this Romans have nothing to boast of in front of us. There is not a thought which could not be expressed in Russian.

In the middle of the eighteenth century this was wishful thinking which had even less foundation in fact than similar paeans to the sixteenth-century English. But due to the efforts of nationalist intellectuals in just a few decades a rich language did emerge; it was to become equal to any and surpassed by none in beauty and power of expression. In the case of Russia, too, and perhaps even more clearly than in other cases, language was not a foundation of nationalism, but its product.

Orthography

M. Sebba

1. Introduction

Orthography is taken here to mean a system of characters or symbols used for writing a language, together with the conventions associated with its use. Orthography is often treated within linguistics as though it were a socially neutral technology for writing, drawing its theory mainly from phonology. However, social and cultural issues are pervasive in orthography, so that it is reasonable to speak of a 'sociolinguistics of orthography' although there is as yet not a well-developed body of theory in this area. Orthographies—an integral part of *literacies*—often become bound up with the cultural identities of their users, whether they be sub-groups (e.g., adolescent peer groups) or entire language communities; as such they can become powerful markers of group identity. In addition, orthographies have been used to establish boundaries between languages, to set distance between what might otherwise be considered varieties of 'the same' language, and to control what literature speakers of a language may have access to.

2. Two Levels of Symbolism

In writing systems, characters (for example, the letters of the Roman alphabet) are used to represent elements of the language system. For example, in an alphabetically written language like English, there is an association between the letter ⟨z⟩ and the phoneme /z/, though it is fairly easy to find exceptions, like ⟨pizza⟩ ([pi:tsa])—in this case, a consequence of language contact (see *Borrowing*). This is one level of symbolism—a correspondence, sometimes more perceived than actual, between sounds and symbols, or between words and symbols in a language with a logographic writing system.

A second level of symbolism derives from the way that writing is *used*—from the fact that it is a necessary part of a set of social and cultural *practices* surrounding and involving literacy. Writing systems

669

become part of the social and cultural history of the communities which use them, and both the writing system as a whole, and the individual characters of which it is made up, may acquire strong symbolic associations.

For example, in the aftermath of the break-up of the Soviet Union, there have been several cases of language communities replacing Cyrillic-based writing systems introduced during the Soviet period, with older, traditional writing systems. Cyrillic itself had been introduced to some of these languages only after a period of Romanization, as the negative associations of Cyrillic from the Russian imperial era had been too strong to allow its direct introduction.

Equally strong symbolism may attach to individual letters or characters, especially in cases where group identity or boundaries are at stake. For example, in lengthy, heated debates over the best orthography for Haitian Creole, the disputed letters ⟨c⟩ and ⟨k⟩ took on symbolic significance. ⟨c⟩ was seen variously as a symbol of French colonial dominance, or, more positively, of membership in *la Francophonie*, the wider French-speaking community of nations. Meanwhile ⟨k⟩ represented cultural (and by extension, economic) independence from France, but was also associated with non-Catholic missionaries, with English, and by association, with regional domination by the United States (Schieffelin and Doucet 1994).

The processes of standardization (see *Standardization*) and prescription add a further dimension of symbolism. Where a particular standard has been prescribed, a cultural meaning can be produced by flouting it. This is well illustrated by the unconventional spellings associated with advertising, adolescent magazines, and graffiti (see below).

3. Orthographies as Sociolinguistic Problems

Sociolinguistic research has tended to address orthographic issues in two areas only: *language planning* and *education*. Fishman (1977) is an important collection on the former; Augst (1986) deals largely, but not exclusively, with the latter. The language planning literature tends to focus on how to find the 'best' orthography for a language, taking into account both linguistic and (sometimes) sociocultural factors. For most of the last century, the conventional view has been that a phonemic orthography is always preferable to a non-phonemic one. However, this leaves undecided the issue of whether the orthographic conventions should follow those of another widely used language—for example the dominant official or colonial language in the region—or should diverge as much as is prudent from that language. In the first case, literacy using the orthography would be seen as *transitional*, leading to literacy in the dominant language. The second possibility might be favored by a language community anxious to establish (or maintain) cultural

independence. By making their language *look different* on the page from other, competing languages, they can assert its distinctiveness. Choice of an orthography can thus have profound social consequences in terms of future development of a language community. Educational concerns usually center around ease of learning of orthographic conventions. Teachers who find their pupils struggling with a conventional orthography are often advocates of reform; but teachers are also often opponents of reform, unwilling to act as conduits for a new set of conventions which they may see as confusing. Since the evidence about which conventions may be learnt most easily or effectively is often not very decisive, educational arguments in debates about orthographic reform tend to be overshadowed by more emotive issues relating to national and cultural identity.

4. Orthographies as Symbols of Group Identities

Particular orthographic choices may be motivated by a desire to keep languages separate, or to create symbolic distance between two similar languages or varieties. Often there is a deeper political or religious motivation for this, as in the case of Polish, which developed a tradition of using digraphs for sounds which, at the same time, were starting to be written using diacritics in Czech. The cultural and—especially—the religious divide, which separated the Poles and Czechs, meant that diacritics were unacceptable to the Poles (Rothstein 1977).

Even a single character may take on significance as a symbol of group identity. Bird (2001) describes how Bamileke speakers who are literate in Bamileke 'strongly identify' with the barred-u symbol ⟨ʉ⟩, which 'iconifies the strong cultural unity of the group with respect to the languages outside the group.' Neighboring languages have the same vowel sound, but it is written differently. Thus ⟨ʉ⟩ has come to symbolize a cultural boundary, between Bamilekes and 'others.' There are parallels here with the way that specific pronunciations of a phoneme can become iconic of a whole group (e.g., speakers from a particular class or region).

Orthographic controversies such as those in Galicia (over whether Galician should look closer to Spanish or to Portuguese: Alvarez-Caccamo and Herrero Valeiro 1996) and German (over a relatively minor spelling reform) often reflect underlying political and ideological debates and insecurities. For example, one view of the German orthographic disputes of the late 1990s is that they were about the German language itself 'as a signifier of cultural and national identity.' (Johnson 2000: 120)

5. Orthographies as Gatekeepers

A common objection to spelling reform is that it will deprive future generations of their heritage by

making earlier writings inaccessible or accessible only on a selective basis. Although traditionalists may exaggerate the extent to which this will happen (for example, the opponents of the recent German spelling reform claim it will lead to a 'culture break,' although it will alter only 0.05 percent of all words in running text), orthographies have historically often been used to control what speakers of a language may (conveniently) read. Across-the-board replacement of one writing system for another (for example, replacing Arabic script with Roman for writing Turkish) will ensure that within one generation, older literature can be accessed only selectively by speakers of the language. Spelling reform is less likely to have such a dramatic effect, but can nevertheless lead to older texts being marked out as 'archaic.'

The treatment of loan words is often an issue in spelling reform. For example, most words of French origin, which are spelt in French with ⟨c⟩ may in Dutch be spelt with ⟨c⟩ or ⟨k⟩. The variants with ⟨k⟩ are often preferred by Flemish writers because they differentiate Dutch from French—an issue in the cultural politics of Belgium. The variants with ⟨c⟩, on the other hand, were favored at one time (at least in The Netherlands) because they appeared more 'cultured' than those with ⟨k⟩ did; and ⟨k⟩ may be unpopular with some Dutch writers because it is associated with German. When the Malay language was written using Arabic script, Arabic words could be incorporated easily, and their influence was pervasive. The adoption of the Roman alphabet for Malay opened the way for non-Arabic loans, and made it necessary to adapt Arabic words to the new writing system; this could be (and was) seen either as the removal of a cultural barrier, or as a threat to the traditional language and culture.

6. Orthography as Resistance

Before complete standardization is achieved, many languages go through a period where considerable variation in spelling is normal. English spelling, for example, was standardized first in printed texts—through the practices of printers and typesetters—but variation in personal, non-printed writing was the norm until a much later date. Typically, however, orthographic variation is seen as inappropriate in a standardized language (Norwegian is an exception). Difficulty for learners is often cited as a reason why variant spellings should be forbidden. The result is that few spaces exist where users of the language can legitimately use non-standardized spellings. Where these do appear, they are often the subjects of attacks by prescriptivists who use them as evidence of falling standards of 'literacy.'

In spite of the relative inflexibility of spelling conventions in languages like English, there is some scope for variation in norms. The British/American spelling divide is well known. A similar split exists between Portuguese in Portugal and in Brazil, despite an accord (1990) which was intended to prevent this.

Individuals may also use spellings which vary from the local norm. Personal names are one area where some scope exists for 'creative' spelling. Advertising is another. Non-legitimated types of writing such as graffiti are often the site of intentionally oppositional non-standard spellings. In England, adolescent graffiti often uses deliberate misspellings such as ⟨woz ere⟩ for ⟨was here⟩. In Germany, Androutsopoulos (1999) has noted that unconventional spellings correlate well with the strength of anti-establishment attitudes in small-circulation magazines read mainly by adolescents; the more oppositional the discourse, the more likely are 'deviant' spellings. In Spain, spellings which use ⟨k⟩ where the standard Castilian orthography requires ⟨c⟩ or ⟨qu⟩ (for example, *ke* for *que*) are widely used among anarchists and members of anti-establishment subgroups.

7. 'Postcolonial' Orthography

The fact that certain characters, diacritics, or digraphs may become so closely associated with a language and its users means that those symbols become candidates for removal when political changes take place. For example, Euskara (Basque) now differentiates itself from Spanish conventions by using ⟨k⟩ rather than ⟨c⟩, ⟨ni⟩ for Spanish ⟨ñ⟩, and the digraphs ⟨tz⟩, ⟨ts⟩ and ⟨tx⟩ to represent affricates.

The Dutch digraph ⟨oe⟩ for /u/—which is not shared with any other European language—was replaced in the official orthography of Indonesia shortly after independence (ca. 1947) and in the official orthography of Surinam, also in the post-independence era (1986).

However, at the same time as establishing symbolic independence from the former colonizer's language, these orthographic changes have brought the languages more in line with international practice and, arguably, with English, the internationally dominant language.

8. Conclusion

The embeddedness of orthography within the literacy practices of a culture means that specific signs, especially those which are not shared with other written languages, carry a symbolic load over and above their function as phonological or logographic symbols. One result of this is that orthography planning is as much a matter of culture (and cultural politics) as of linguistics. Another is that orthographies tend to be resistant to change, especially rapid or enforced change, like other long-standing aspects of a community's culture.

Prescription in Dictionaries

L. C. Mugglestone

Modern dictionaries, in line with the approaches of twentieth-century linguistic study, attempt to describe rather than to prescribe lexical usage. However, many earlier dictionaries, and particularly those produced before the mid- to late-nineteenth century, were concerned rather to lay down rules of correctness for the use of individual words and meanings, and to proscribe other usages as 'incorrect.'

The desire to erect a standard language, often highlighted by the workings of Academies, such as the Académie Française in France, or the Accademia della Crusca in Italy (see *Academies: Dictionaries and Standards*) often led in these early dictionaries to a strong normative bias in accordance with prevailing attitudes of linguistic purism and codification. In terms of lexicographical practice, this is often evident in the principles of lexical selection adopted, as well as in the employment of restrictive usage labels and value judgments. Dr Johnson's preface to his *Dictionary of the English Language* (1755) can be seen to exemplify some of the notions of linguistic control behind prescriptive methods in lexicography, as in his conception that 'it is the duty of the lexicographer to correct or proscribe' the 'improprieties and absurdities' present in every language. A similar prescriptive bias underlies his decision to exclude the 'casual and mutable' diction of the merchant classes from his dictionary on the grounds that it is merely 'fugitive cant, which is always in a state of increase or decay ... and therefore must be suffered to perish with other things unworthy of preservation.' Though Dr Johnson does acknowledge the futility of trying to embalm the language by means of a dictionary, the prescriptive mode nevertheless influences a number of his lexicographical practices, as in the usage labels such as 'barbarous,' 'low,' and 'ludicrous' which he adopts for those lexical usages which, though current, he disapproves of.

1. Usage Labels

Usage labeling, though not necessarily prescriptive, can often take on these implications, so that the word *lesser*, for example, is, in Dr Johnson's *Dictionary* of 1755, condemned as 'a barbarous corruption of less' in spite of its use in English since 1459. Though prescription may be less explicit in these areas in modern dictionaries, it may still operate. *The Oxford English Dictionary*, for example, appends the paragraph sign ¶, by which it designates 'catachrestic and erroneous' usage, to the word *refute* used in the sense 'deny' in spite of both the increasing currency of such a usage in the late twentieth century, as well as the accompanying use of illustrative citations from authoritative publications such as *The Observer*. Users of dictionaries, however, seem to regard the provision of usage labels as essential, and their absence in Webster's *Third New International Dictionary* of 1961 was seen as an abdication of that lexical responsibility and linguistic control popularly (if erroneously) attributed to the preserve of the dictionary. It remains paradoxical that whereas lexicographers on the whole attempt to describe usage without imposing value judgments, the users of such dictionaries tend to see them as encoding linguistic standards, with the result that the inclusion of new words is seen as a legitimization of their existence, and the necessary delay in recording new meanings of older words as proof that such changes have not occurred or are 'incorrect.'

Reversing Language Shift
J. A. Fishman

Before the advent of sociologically better-informed sociolinguistic theory it was not uncommon to attempt to explain the waning of languages via recourse to such intuitively popular factors as 'proximity to more powerful language' (often referred to cryptically as 'geography'); 'conviction that the language be retained' (often referred to as 'positive language attitudes' or 'motivation'); and absolute number of speakers (often referred to as 'speech-community size'). The problem with such theoretically innocent explanatory attempts is that they do not spell out or relate to societal processes, whether of intra-group interaction or inter-group interaction, that is, they are basically neither sociological (and, therefore, not sociolinguistic) nor are they related to any body of disciplined inquiry or application. 'Geography,' 'attitudes,' and 'size' are all folk concepts that need to be sociologically reinterpreted and operationalized into their manipulable societal counterparts. Reversing language shift efforts are particularly in need of both conceptually integrated social theory and a structured set of priorities for application that derives from such theory. What follows is an effort along such lines.

1. What is 'Reversing Language Shift (RLS)'?

RLS constitutes that corner of the total field of status planning that is devoted to improving the sociolinguistic circumstances of languages that suffer from a prolonged negative balance of users and uses. It is not necessarily entirely an applied field of endeavor, since any hope for successful application—here as well as elsewhere—depends on the prior development of conceptually integrated diagnostic and corrective theory. The initial aim of the field of 'language maintenance and language shift' (Fishman 1964), was that the referents on both sides of the conjunction receive equal attention. Unfortunately, that has not proven to be the case and the negative process has received far more attention than has the positive one. Perhaps that is the result of a general bias, common both to modern humanistic and social science scholarship and to various ideologies of the left, center, and right alike, to assume (and, at times, even to prefer) the uniformation and massification of culture, based upon the massification and unification of the market and of modern technology across cultural boundaries. This bias focuses upon and prefers social class to ethnic stratification as the major societal accompaniment to globalization.

As a result, 'the other side (or the plus side) of the ethnolinguistic ledger' has tended to be neglected, if not ideologically stigmatized. The study of RLS represents an attempt to redress the perspective balance and to direct attention to the fact that not only are millions upon millions of speakers of small languages on all continents convinced of the creative and continuative contributions of their languages (usually their mother tongues but sometimes their historically associated religious languages) to their personal and collective lives, but that many millions are also engaged in individual and collective efforts to assist their threatened mother tongues to reverse the language shift processes that threaten or that have engulfed them (see *Endangered Languages*).

Language shift (see *Language Maintenance, Shift, and Death*) can impinge on various societal communicative functions and, accordingly, the study of RLS must be concerned with the entire sociofunctional profile of language use in any particular community under study. However, sociofunctional features of language use are neither universals nor fixed and they must, in all honesty, be established anew empirically whenever a hitherto unstudied (or not recently studied) ethnolinguistic collectivity is (re)examined. Nevertheless, due to the worldwide encroachment of western-derived modernization, it is possible to make heuristic use of a parsimonious subset of functions that tend to be rather generally encountered (except where undislocated non-western cultures still hold sway, Fishman 2001). In our discussion, below, these sociofunctions will be discussed from the point of view of RLS efforts for the purpose of attaining and augmenting intergenerational mother-tongue transmission. The intergenerational transmission of regional languages (lingua francas), of languages of wider econotechnical communication, or of religious classicals (in general, the intergenerational transmission of additional languages for special purposes) has been discussed elsewhere (Fishman 1991: chap. 12), although it should be stressed that the theoretical underpinnings of that discussion are the same as those which follows here.

2. A Conceptually Parsimonious Approach to Describing and Prescribing: The Graded Intergenerational Dislocation Scale (GIDS)

It would be conceptually parsimonious to adopt an approach to analyzing RLS situations such that it would simultaneously (a) lend itself to comparative (that is, to between-language) description or analysis; and also (b) indicate the nature (location) and intensity (seriousness) of the sociofunctional disarray impacting any particular cases under discussion.

Table 1. Toward a theory of reversing language shift.

> **STAGES OF REVERSING LANGUAGE SHIFT AND SEVERITY OF**
> **INTERGENERATIONAL DISLOCATION**
> (read from the bottom up)
>
> 1. Educational, worksphere, mass media, and (quasi-)governmental operations in Xish at the highest (nationwide) levels
> 2. Local/regional mass-media and (quasi-) governmental services in Xish
> 3. The local/regional (i.e., supra-neighborhood) worksphere, both among Xmen and among Ymen
> 4b. Public schools for Xish children, offering some instruction via Xish, but substantially under Yish curricular and staffing control
> 4a. Schools in lieu of compulsory education and substantially under Xish curricular and staffing control
>
> II. *RLS-efforts to transcend diglossia, subsequent to its attainment*
>
> 5. Schools for Xish literacy acquisition, for the old and/or for the young, and not in lieu of compulsory education
> 6. The organization of intergenerational and demographically concentrated home–family–neighborhood efforts: the basis of Xish mother tongue transmission
> 7. Cultural interaction in Xish primarily involving the community-based older generation (beyond the age of giving birth).
> 8. Reconstructing Xish and adult acquisition of XSL
>
> I. *RLS to attain diglossia (assuming prior ideological clarification)*

Simply put, RLS is in need of an approach to sociofunctional analysis which will both describe the situation and prescribe the necessary ameliorative steps, at one and the same time, in so far as the needs of threatened languages are concerned after an intergenerational period of Western-impacted dislocation. Table 1 represents an effort along those very lines.

Table 1 must be read from the bottom up, to appreciate the fact that the RLS-circumstances and efforts toward the bottom of the table represent more fundamental stages of sociofunctional dislocation. Stage 8 indicates the greatest dislocation of all (from the point of view of achieving intergenerational mother tongue continuity), namely, a language which has lapsed into general disuse sufficiently long ago that it is now in need of reconstruction from shreds of evidence that can be provided by its last speakers and other incomplete and even vestigial sources. In order to shorten the number of steps in the table (the number can be greatly increased if finer functional distinctions are desired), stage 8 also includes those languages for which ample written evidence is available but which have lost their native speakers to such a degree that these languages must first be learned as second languages before further sociofunctional repertoire expansion can be envisioned for them (see *Salvage Work (Endangered Languages)*). All in all, stage 8 represents maximal dislocation precisely because it constitutes Xish language use outside of natural society, that is, outside of daily effortless societal interaction among individuals

actually implementing Xish ('ex-ish,' the abbreviation for any particular language undergoing shift) in their normal, ongoing, community-based ethnocultural lives.

Note, however, that no evolutionary or implicational (required) progression is implied. Even the attainment (or implementation) of vernacular cultural interaction on a community basis is insufficient for intergenerational mother tongue continuity if the community of speakers consists of individuals who are primarily past childbearing age (stage 7). Indeed, it is precisely the fashioning (attainment or retention) of Xish-implementing intergenerational and demographically concentrated home–family–community life, and the diglossic sheltering of such life from the inroads upon Xish intimacy that can stem from Yish ('why-ish,' the abbreviation for the competitively stronger language surrounding Xish), that is the *sine qua non* of mother-tongue transmission (stage 6). All efforts that come later may (and that should optimally be so regulated that they do) help shelter stage, cannot substitute for it, nor, as we will see, can they directly help stage 6 insofar as its creation or attainment are concerned. In addition certain stages (e.g., stage 5) may be totally unnecessary given certain contextual circumstances. Other characteristics of Table 1, and the underlying theory that it represents, will become clear from the ensuing discussion below, of ambivalences that often enfeeble RLS efforts on behalf of intergenerational mother tongue continuity.

In general terms, stage 6 may be viewed as the dynamic fulcrum of a field of forces. If stage 6 is not attained and vigorously retained, the less contributory to the intergenerational continuity of Xish will be the RLS efforts concentrated at other stages. Efforts closer to stage 6 are more nearly under Xish community control and, therefore, do not depend crucially on Yish support, funding, cooperation, or permission. Although the approach sketched here assumes that something can always be done on behalf of threatened languages (even for those at stage 8), it clearly implies that not everything that is done will contribute with equal ease and directness to intergenerational mother-tongue continuity. This conclusion (often a contra-intuitive one for RLS workers) will be spelled out in the three sections that follow.

3. Some Ambivalences

3.1 Ambivalence 1: The Premature Attraction and Distraction of Pursuing High Status/Power Functions

The striving toward Xish implementation in, and control of, econotechnical modernity, a striving which is so typical of the modern situation which we have assumed generally to be part of the total language shift process impinging upon Xish, leads to an overly early concentration on stages 4 through 1 among those working on behalf of RLS. Such premature efforts to cross the continental divide between *attaining diglossic L protection for Xish* and *dismantling diglossic L status for Xish in favor of diglossic H status* (or even monolingual Xish self-sufficiency) is evidenced by rushing into efforts on behalf of Xish schooling-in-lieu-of-compulsory-education and even by a stress on Xish use in the non-neighborhood worksphere, media and governmental operations. RLS efforts, which pursue such goals prematurely, are inevitably faced by several problems. On the one hand, these goals engender intergroup conflict precisely with respect to functions in which Xmen are weakest relative to Ymen and where they will most often initially require the greatest amount of Yish support and cooperation, even if only a nominal Xish presence is to be approved and funded.

Unfortunately, any nominal Xish presence in upper status and power functions will more often than not be completely overshadowed (if not totally eclipsed) by the vastly more frequent and often far superior Yish presence in those very same functions. The unequal struggle for 'recognition' in these high status and power functions frequently renders RLS efforts completely hopeless, disillusioned, and innocent of concrete results. What is worse, the overly-early concentration on high status and power goals not only does not feed back directly to stage 6 but often postpones the tackling of stage 6 until it is too late from the point of view of capitalizing on still

available Xish demographic concentrations and on Xish speakers who are still of childbearing age. Trickle down theories that claim that power functions imply and guarantee intimate mother tongue acquisition and use are seriously mistaken, unless the former are specifically controlled and oriented via feed-back systems so as to constantly keep the latter at the forefront of attention and concern. It is ever thus for non-dominant Xs, where social dynamics flow effortlessly from Y to displace X but never in the reverse direction.

While the attainment of type 4a schools (primarily Xish staffed and regulated) or even 4b schools (primarily Yish staffed and regulated but intended for Xish children) certainly constitute worthwhile RLS goals, nevertheless, many Yish-dominated years must pass before the graduates of such schools can found new Xish speaking families of their own. Of course, such schools can serve to further motivate and protect stage 6, but stage 6 must be alive and well for such motivation and protection to transpire. Finally, and specifically in relation to schools, various postmodernization processes have served to render the school–home continuity relationship more tenuous than ever before (Fishman 1991: chap. 13), even for Yish, thereby rendering schools above the optional type 5 quite questionable investments of time and effort for RLS movements that are still weak and without stage 6 foundations securely under their control. Successful and constant feedback from stage 4 to stage 6 requires ongoing out-of-school and after-school involvement of school staff in most home, neighborhood, and community efforts from the earliest toddler years onward. The Maori Kohanga-Reo nursery schools did just that, with some success for Maori revernacularization.

The Irish RLS case was long a prime example of the inadvisability of disproportionate concentration on stage 4 relative to stage 6, and of the resulting institutionalization of Irish as an occasional, formal second language among the school-focused middle class. Each successive generation in Ireland has nevertheless started, and generally still starts out (even after three-quarters of a century of governmentally sponsored RLS efforts), totally without Irish when it arrives in school, rather than as a mother tongue and informal medium among members of Irish society more generally. The current case of battle fatigue among Irish RLSers, and the substantial peripheralization of their struggle vis-à-vis the interests of society more generally, can be attributed to their precipitous over-concentration on advanced GIDS stages. The latter do not spontaneously feedback to intergenerational mother tongue continuity and require substantial ingenuity (as is always the case for water to flow uphill) if they are to do so even when linkages for that purpose are kept prominently in mind.

675

3.2 Ambivalence 2: First Attaining and Then Overcoming Diglossia, and Doing Each at an Appropriate Time

If the headlong rush into highly improbable (if not totally impossible) serious competition with Yish represents a distinct danger for the success of RLS efforts on behalf of intergenerational mother tongue continuity, then the insufficient pursuit of substantially self-regulated modern status and power functions, even when such can be erected upon a strong stage 6 base, constitutes an equally great (although far less common) danger to such efforts. A disproportional stress on traditionalism, revivalism, or other expressions of 'anthropological revitalization' exposes RLS efforts to the risk of being rejected by Xmen who seek a path marked by both modernity and Xishness. In the absence of sufficient RLS interest in rationally defining the priorities to be followed in forging such a path, RLS may come to be viewed as anachronistic or backward looking. More symbiotic alternatives to it (combining Xishness and Yish in some fashion) may come into being (e.g., movements on behalf of 'Xmen-via-Yish' as rivals and competitors with the RLS movement per se among Xmen). Some of the ultra-Orthodox Yiddish speaking communities in New York are exposed to this very dilemma today as young people protest against their community's overly slow progression from stage 4 to stage 3. The insufficient availability of stage 3 functions under ultra-Orthodox sponsorship is leading more and more young people into the Yish controlled worksphere (and into social mobility via that worksphere), with evident effect on their own intragroup use of Yiddish. Community leaders, however, are concerned about youngfolks entering stage 3 wholeheartedly, because of its manifold links with the Yish world. The dilemma here needs to be recognized because of its 'damned if you do, damned if you don't' potential. It is a very resource-demanding stage and one that few minority communities can really control and link back to stage 6.

Given that both the premature abandonment of the diglossic (see *Diglossia*) protection of stage 6 and the overly prolonged inability to transcend the encapsulation of stage 6 are clearly problematic vis-à-vis RLS success, it is, nevertheless, clear that the attainment of diglossic protection for Xish by weak RLS movements lacking in stage 6 is infinitely more common and difficult (and less glamorous) than is its subsequent gradual transcendence by an RLS movement with a secure basis in everyday intergenerational life. RLS movements are ethnicity linked and they must build upon the putative kinship claim of all ethnicity movements in order to counteract the blandishments of greater (and often even purportedly unlimited) individual social mobility via Yish and through Yish institutions. Such blandishments render Xmen less ideologically disposed toward the behavioral and motivational prerequisites of RLS movements on behalf of the 'Xmen-via-Xish' model. The Irish and Frisian movements are good examples of the difficulties encountered in this very diglossia attaining connection. Stage 6 never having been reconstituted on a sufficiently ample base (a base which many ultra-Orthodox Yiddish speakers *have* secured), there is no widely available safe harbor in daily life against the influences of the upper Yish-controlled stages.

Furthermore, the transcendence of diglossic bilingualism into a virtually monolingual Xish *de facto* control of everyday public and intergroup life, is often considered by Ymen to be unattainable without civil strife. However, the actual incidence of civil strife is more genuinely related to the removal of authoritarian control after periods of both long term and short term deprivation (Fishman and Solano 1990) than to RLS processes or other ethnolinguistic processes themselves. The Franco-Canadian and the Catalan RLS cases are both examples of relatively successful negotiations of this difficult passage, the latter being almost entirely without serious intergroup recriminations between indigenous Catalans and immigrant Caitlin speakers thus far. Note, however, that without successfully attaining and maintaining stage 6, no sustained transcendence of that stage is possible. There is a dilemma here of no mean proportions.

3.3 Ambivalence 3: The Difficulty of Planning Spontaneity and Intimacy

The basic problem of weak RLS movements is whether the attainment and maintenance of stage 6 is at all susceptible to planning. Given that intergenerational mother tongue transmission is a function of the childhood intimacy and spontaneity that characterizes home–family–neighborhood life, this problem boils down to whether this complex of culturally infused interpersonal processes can only be informally cultivated *in vivo*, so to speak, or whether it can be fostered by rational planning. The evidence supporting the latter alternative is, quite frankly, sparse indeed. The major RLS success cases of the twentieth century generally entered the fray while their stage 6 processes were still (or already) rather intact at least in some language islands (see *Language Enclaves*). Attempts to build stage 6 directly (e.g., the community and housing schemes of Irish RLS efforts in the mid- to late-1980s) have demonstrated how elusive the informal interaction processes really are and how difficult it is to really plan them or to do so without smothering them. Yet the revernacularization of Hebrew in Palestine on the part of secular (indeed, anti-clerical) Zionists was accomplished precisely along the lines of giving priority to self-regulatory home–family–community building for the attainment of

intergenerational mother tongue transmission. The movement reached its goal during the immediate pre- and post-World War I decades, much before any power and status functions (beyond the settlements and their community-controlled fields, chicken-coops, nursery–kindergartens, and elementary schools) were seriously entertained on a broader societal base. Years of child-rearing by specially trained care givers transpired in a quite separate children's home, with only very occasional visits on the part of the children to their parents, until the children taught the parents the revived vernacular. Such back-linkages between higher stages and stage 6 require careful and constant attention, so that neither insufficiency nor smothering transpires.

Obviously there is also considerable need for ideological clarification (more about this below) and for neighborhood organization expertise and organization-theory expertise in general (on the latter, see Hart 2001) within the total RLS enterprise. Nevertheless, the dilemma, which underlies this third area of ambivalence, must be recognized as such. Intergenerational mother tongue transmission depends on processes which have too long remained overlooked by RLS movements but, to make matters worse, even when squarely acknowledged, these processes are difficult to plan because they require the establishment and fostering of interactional contexts and relationships which are inherently difficult to plan and to cultivate. Doubly so as long as Xish-imbeddedness in Yish-dominated everyday sociocultural processes remains uninterrupted. It was the very ability of the new Zionist settlements to break away from their dependence on all other Jewish and non-Jewish norms and associations, both in the diaspora and in Palestine itself, that made it possible for them to create home–family–neighborhood (=settlement) contexts in which their preferred Xish was protected and could finally attain intergenerational roots. It was only thereafter that efforts to hebraize others and higher sociocultural processes were successfully focused upon. On the other hand, Eliezer ben Yehuda, who had focused upon such higher order processes from the very outset (ca. 1890) was distinctly unsuccessful in vernacularizing Hebrew, regardless of the subsequent symbolic mythologization of ben Yehuda in that very connection.

4. A Glance at a Few Selected Cases

Table 2 presents data on the standing of a baker's dozen of RLS cases with respect to their present GIDS status. These cases are drawn from three continents (North America, Europe and Asia/Pacific; for Latin American and African cases see Fishman 2001) and include both indigenous and immigrant groups. Both the right and the left margins of Part A of the table consist primarily of the GIDS stages that

were presented in Table 1, above, and that have provided the basis of most of the foregoing discussion. The only addition to the table proper is the notation IC (ideological clarification) which has been scored on a three point scale ($+$, $+-$, $-$) reflecting the availability of positive ideological consensuality within the 13 studied RLS circles today. The total GIDS score (referred to as Ts) for each case consists of the grand total of all of the numbers representing stages at which major RLS efforts are concentrated today on behalf of that case. Higher total scores indicate efforts that are still focused on societally more basic dislocated stages. The highest (most dislocated) scores are obtained for Maori, Irish, and Yiddish in secularist circles in New York City and selected Australian Aboriginal 'outstation' cases. The lowest (least dislocated) scores are obtained for Hebrew in Israel, French in Quebec, Catalan in the Autonomous Catalan Community, and Yiddish in ultra-Orthodox circles in New York. Another way of estimating the current relative positions of these 13 communities is by examining their mean GIDS scores. The correlation between the Total GIDS score and the Mean GIDS score is 0.79, confirming that the Ts is not merely an artifact of the number and variety of efforts involved.

It is quite clear from Part A of Table 2 that there are some cases significantly involved in efforts above the 'continental divide' that are, nevertheless, still in a poor state of health with respect to their overall RLS status (e.g., Irish and Basque). There are also (and even more obviously) a few cases where there is little if any ideological focus (IC) on RLS which are doing relatively well with respect to their overall RLS standing (e.g., Navaho [selected reservation] and ultra-Orthodox Yiddish in New York). Part B of Table 2 reveals that the consideration that really seems to distinguish between cases doing well and cases doing less well or poorly, as far as RLS is concerned, is whether stage 6 (home–neighborhood–community) is substantially under self-regulatory RLS auspices.

The average total GIDS score for the four cases in which this is so is 3.75, whereas the average total GIDS score for the nine cases in which it is not so is 15.75. The difference in total GIDS scores between cases with and without positive ideological consensuality is less impressive (10.20 vs. 14.13), although it too is clearly in the right direction (detailed information concerning all 13 cases in the early 1990s can be found in Fishman 1991 and, once again, for the early 2000s in Fishman 2001). Current ambivalence regarding the importance of Hebrew in Israel (particularly in comparison with the unanimity as to the importance of the 'Xmen-via-Xish' position among Francophones in Quebec and among Catalans in the Autonomous Catalan Community) is attributable to a growing philosophical pluralism on

this issue. This pluralism can be attributed to the post-struggle phase, which Xish has now achieved there. The IC analysis clearly implies that even an RLS-engineered ideological consensus (by no means the same as spontaneous 'positive attitudes' or 'positive motivation' relative to Xish) is of clearly lesser RLS importance than establishing Xish supremacy vis-à-vis the societal processes of everyday home–family–community life.

Obviously, Table 2 does not try to show the historical development that has occurred with respect to the RLS statuses of the speech communities involved. Clearly, it deals only with the reasonably current situations in each case. A series of such tables, decade by decade from the beginning of the twentieth century, would unambiguously reveal which cases have advanced, which have regressed, and which have remained stationary with respect to their respective RLS statuses. For relevant informa-

tion for one such analysis in a less compressed non-tabular, narrative form see Fishman (1991).

5. Some Concluding and Summary Observations

Our discussion has tried to help clarify why 'geographic' considerations, 'absolute size' considerations and attitudinal/motivational considerations cannot be considered either conceptually/analytically fruitful or, indeed, manipulably rewarding dimensions in connection with understanding RLS differentials. Letzeburgisch, the vernacular of Luxembourg, is 'next door' (indeed, surrounded by) two world languages, French and German, both of which are even part of the very Xish identity-and-behavior pattern that Letzeburgisch itself serves to clinch. Furthermore, Letzeburgisch mother tongue speakers constitute a rather small speech community and one which gives its mother tongue rather little explicit ideological attention. Rather than fixating on

the former non-manipulable intra-group considerations this article has emphasized intergroup processes and a search for manipulable 'planning' considerations. Nevertheless, a number of ambiguities and dilemmas must be recognized as plaguing or rendering extremely difficult the pursuit of RLS. Even ameliorative efforts that are well understood, correctly sequenced, and interrelated are not thereby necessarily successful, but the pursuit of folk notions, the lack of strong linkages to the crucial stage 6 and the childish belief that 'doing anything (or a little bit of everything in random order) is necessarily better for RLS than doing nothing' are all definitely contra-indicated. They only serve to squander time, resources, and trust, commodities that are in short supply and that need to be wisely used and husbanded.

Intergenerational RLS may safely focus on the school, on the church, or on the workplace if specific non-mother tongue functions are being aimed at. However, if intergenerational mother-tongue transmission is being aimed at, there is no parsimonious substitute for focusing on the home–family–neighborhood–community processes which bind together adults and children (most frequently, but not only, grandparents and grandchildren and parents and children) in early bonds of intergenerational and spontaneous affect, intimacy, identity, and loyalty. This is not to say that this arena is itself sufficient to guarantee that mother tongue-focused RLS efforts focused upon it will succeed, but it is to say that RLS control of this arena is necessary, a *sine qua non* for such success. Subsequent stages can provide it with additional latitude and instrumental feedback re-

inforcement. Much before diglossic arrangements are fully transcended there are types of schooling (particularly type 5 and 4a) that can support this arena materially and with only meager dependence on Yish regulation, approval, or support. Thereafter, Xish with a firm, demographically concentrated community base can increasingly pursue economic and even political co-regulatory power. The increasing attainment of such power leads to cultural autonomy arrangements and to realistic possibilities of further political autonomy arrangements as well.

School Language Policies
D. J. Corson

School language policies are viewed by many in education as an integral and necessary part of the administration and the curriculum practice of modern schools. A language policy is a document compiled by the staff of a school, often assisted by other members of the school community, to which the staff give their assent and commitment. It identifies areas in the school's scope of operations and program where language problems exist that need the commonly agreed approach that is offered by a policy. A policy sets out what the school intends to do about these areas of concern; it is an action statement.

1. Origin and Early Developments
In 1966 members of the London Association for the Teaching of English began to develop and extend

their interest in the concept of 'language across the curriculum' by preparing a discussion document entitled 'Towards a language policy across the curriculum' (Rosen in Barnes et al. 1971). This discussion document provided the catalyst for action that its authors had intended. Schools in various places within Britain, in other countries of the British Commonwealth, and in the United States began to develop their own language policies, using the original document as a reference point. In 1975 the point and value of language policies for British schools received official endorsement in *A Language for Life* (The Bullock Report): Each school should have an organized policy for language across the curriculum, establishing every teacher's involvement in language and reading development throughout the years of schooling.

679

Subsequently several influential texts (e.g., Torbe 1980) addressed the need for a whole-school language policy, especially at secondary level, and discussed the implementation of such a policy. As the idea of having school language policies spread, practitioners and theorists began to see potential in them for small-scale but important educational reform: for example Knott (1985) presents novel ideas for researching pupil language use and discovering the attitudes of secondary school staff to language issues; and Maybin (1985) provides practical approaches for working towards a primary school policy for implementation in a culturally pluralist school setting.

2. Language Planning, National Language Policies, and School Language Policies

'Language planning' (see *Language Planning: Models*) is another name for the evaluative approach to the sociology of language (see *Sociology of Language*). Broadly conceived, language planning is concerned with any problem area in which language plays some role: it is the organized pursuit of solutions to language problems. Following in the language planning tradition as they do, national language policies are comprehensive and coherent documents that enable national decision makers to make choices about language issues in a rational and balanced way. Australia's 'National Policy on Languages' released in 1987 is an example of a policy of this kind.

In spite of great advances in language planning, researchers in the area have paid very little attention to the school as the basic context for language change. Even those rare texts that have linked language planning with education (Kennedy 1984) tend to address education as a macro phenomenon. However official documents have begun to suggest the need for formal school-level planning. In 1985 *Education for All* (The Swann Report) responded to the growing pluralism in British schools by warning that 'unless there is a school language and learning policy across the curriculum there will be a wastage of effort and often confusion' (see *Black English in Education: UK*). The micro setting of the school as a site for language planning in now receiving more attention, beginning with research studies in New Zealand and Canada that address the role of the school as the key agency in language planning. These studies borrow the model of 'language policies across the curriculum' developed for London schools and extend its original focus on mother-tongue concerns to include second language, bilingual, foreign language, and social justice issues (Corson 1999). The studies argue that the social institutions needed to translate the visions of national policies into strategies capable of enhancing individual lives already exist throughout pluralist societies in the form of their schools. It seems a very reasonable thing to ask schools to be responsible for much of the working end of language planning and of national policies that deal with language issues.

3. Administration, Policy Studies, and Research in Education

The design and implementation of a school language policy are ultimately the responsibility of the school's administration, acting through a policy-making group, departmental subcommittees or possibly through the participation of the whole school's staff and community. As a result the applied value of the ideas in school language policies will depend on how well the concept is integrated into the training and professional development of school administrators and curriculum planners. Moreover many types of small-scale and large-scale research will be necessary in schools if policies are to provide adequate and implementable solutions to local language problems. The training of teachers in basic language research methods will need to become more common. A beginning has been made in all these areas (Corson 1998, 2000).

The rise in interest in school language policies coincides with moves in Canada, the UK, the United States, Australia and New Zealand to devolve most educational decision making away from central bureaucracies and down to school level. A groundswell of interest in school policy making of all kinds has resulted. Perhaps much of the impetus for further development will come from the growing need in modern societies to improve the quality of the solutions offered to the problems of large-scale cultural pluralism. Increasing tolerance worldwide in the treatment of linguistic minorities should hasten this development (see May 1997).

Standardization

E. Haugen

Any vernacular (language or dialect) may be 'standardized' by being given a uniform and consistent norm of writing that is widely accepted by its speakers. It may then be referred to as a 'standard' language.

The requirements posed in this definition involve (a) an explicit norm and (b) speaker acceptance. The first is fulfilled by an individual (or a competent group) who selects the forms of one or more dialects and decides on a suitable transcription for the standard. The second is fulfilled by the wide acceptance of the standard as a desirable mode of writing the vernacular. In its initial phase the users of a standard are usually a tightly knit group of elite members (a coterie, a church, an academy) and are only gradually extended to include a whole people or a nation. Throughout the world, language standards are the product of either military conquest, immigration, or commercial contact.

1. History of Standardization

The idea of standard languages arose during the Renaissance in Europe, and it may be questioned whether there were any standardized languages prior to the invention of printing in the fifteenth century. Most standards were preceded by a profusion of scribal varieties, which reflected either the scribe's local dialect or some personal idiosyncrasy.

An example is Sanskrit, which was based on a dialect spoken by Hindus living in northeast India from ca. 1500 BCE. While the spoken dialects kept changing, Sanskrit was codified in the fourth century BCE by the linguist Pāini. After that it became the sacred medium of Hinduism and was preserved in a ritualized form which resembled the modern standards. But it remained the possession of a small coterie of specialists.

Greek has been known since the fourteenth century BCE but its literature was written in several dialects until the Hellenistic period, i.e., the fourth century BCE. It then achieved a fairly unified form known as the koiné, or common language, based on Attic Greek. Modern Greek is ultimately based on the koiné, but is widely different. When Adamantios Korais (1748–1833) in the early years of the nineteenth century conceived the idea of a new standard language for Greece, he adopted a highly literary form, partly based on the koiné, which came to be known as the Katharevousa, or 'pure' language. Modern writers have in part deviated by adopting elements from spoken Greek, the Demotike, or 'popular' language.

Latin began as just another Indo-European dialect in Italy, spoken from the fourth century BCE. But Rome's conquest of the peninsula in 338 BCE laid the foundation for the replacement of the dialects of Latium by the Latin of Rome. Early writers like Plautus and Terence have been credited with writing the first forms of Latin. In the development of Latin, Greek played a large role. The Latin language was then spread by the conquest of what became the Roman Empire. This was for centuries the learned language of European nations, while the spoken vernacular developed into the modern Romance languages. It was roughly codified by Latin grammarians in the early centuries of our era. Even though it was spread widely, the lack of printing kept it from counting as a true standard language.

2. Institutional Efforts at Standardization

The idea of the Language Academy (see *Academies: Dictionaries and Standards*) as an instrument for creating a standard language was launched in Italy by Count Cosimo I of Florence. He founded the Accademia della Crusca in 1582. A generation later Cardinal Richelieu followed suit by founding the Académie Française in 1635. Richelieu gave its 40 'Immortals' the power to encourage all that was 'noble, polished, and reasonable' in the French language, but as has been pointed out, there was hardly one of the members who was trained in linguistics or lexicography. They were really social arbiters whose function it was to decide on criteria of good taste in language. However, they did produce both a grammar and a dictionary of French.

A similar institution was founded in Spain by King Philip V, the Real Academia Español in 1713, designated to 'clarify, purify, and glorify' the Spanish language. Here the first codification had already been made by Antonio de Nebrija, who presented a grammar of Spanish to Queen Isabella in 1492. In its wake other academies were founded in the countries of the Spanish New World. In Germany *Sprachgesellschaften* sprang up with the idea of 'purifying' the German language. In Sweden an academy was established by King Gustav III in 1786. In Hungary one was established in 1830. Arabic academies grew up in Syria, Iraq, and Egypt. A Russian Academy produced a dictionary (1789–94) and a grammar (1802).

Conspicuous here is the absence of any English institution of similar import. There was active agitation for the creation of one in the eighteenth century by persons as eminent as Daniel Defoe and Jonathan Swift. But in typical Anglo-Saxon manner,

681

private enterprise took over. In 1720 the indefatigable Samuel Johnson produced his English dictionary, which fulfilled the needs of the English. The example was followed in the United States by the work of Noah Webster.

After the Reformation the Scandinavian languages were standardized by the translators of the Bible, working in close contact with the royal chanceries. A Danish version of the New Testament came in 1529 by Christienn Pedersen, who also published a Latin–Danish dictionary (1510). The official Danish Bible appeared in 1550. A Swedish New Testament was translated in 1526 and the complete Bible in 1541 under the guidance of the reformers Olaus and Laurentius Petri. An Icelandic New Testament by Oddur Gottskalkson came in 1540. Norway as a dependency of Denmark did not receive a translation of its own, and consequently no standard language.

Two initiatives to create a Norwegian standard were launched in the mid-nineteenth century, after Norway was detached from Denmark in 1814 and got autonomy in a union with Sweden. In 1853 the dialectologist Ivar Aasen devised a norm of Norwegian based on the rural dialects, especially the western ones which retained most of the Old Norwegian quality. He was opposed by the schoolman Knud Knudsen, who in 1856 proposed a Dano-Norwegian norm that took account of the cultivated speech in the cities, especially in Eastern Norway. Aasen's standard was known as *Landsmål* 'Country Language' (now *Nynorsk* 'New Norwegian'), Knudsen's as *Dansknorsk* or *Riksmål* 'Language of the Kingdom' (now known as *Bokmål* 'Book Language'). These two standards have contended ever since for supremacy; in modern times the Nynorsk has captured only one-sixth of the school districts, none of them urban.

In the twentieth century the Scandinavian languages have emphasized the principle of 'language cultivation' (Swedish *språkvård*, Norwegian *språkrokt*, Danish *sprogrøgt*). Beginning with the Swedish *Nämnden för svensk språkvård* ('The Committee for Swedish Language Cultivation') in 1944, a whole series of such committees were established in the Scandinavian countries: Swedish Finland, Denmark, Norway, Iceland, and the Faroes. Each of these countries also has Centers of Technical Terminology, with the special task of unifying the specialized terminologies of their languages. After intense controversy the Norwegian Language Committee was reorganized in 1972 as the Norwegian Language Council (*Norsk Språkråd*) with new guidelines. In 1978 a joint Scandinavian Committee was established with offices in Oslo.

3. Means and Effects of Standardization

As will be seen, the creation and propagation of a standard involves on the one hand the creation of instruments for standardization in the form of grammars and dictionaries, and on the other the presence of a population that finds the standard useful in its communicative efforts. Standardization in effect creates a new language, since it can never capture the entire language nor remain entirely static. Beginning as a reading language, it may in time lead to a new standard spoken language, which may in part be imposed on a population, either by coercion or voluntarily. It usually has a greater prestige than the vernaculars on which it is based and serves to unify the population ruled by a central government.

An example is the switch of Turkish from an Arabic to a Roman script, decreed in 1928 by Atatürk. While this in itself did not change the language, it was accompanied by an increased activity in purifying it from Arabic and Persian elements.

The 'revival' of Hebrew in Israel after its settlement by Jewish groups in the 1900s is a striking example of the adoption of a traditional language as a written standard, resulting in a new spoken vernacular, following the initial agitation of Eliezer Ben Yehuda (see *Reversing Language Shift*). However, the modern vernacular is far from identical with biblical Hebrew. It is said to be influenced by the thoroughly Western substratum of its predominantly Yiddish origins (Yiddish being a dialect of German).

Chinese is not a single language, but several mutually unintelligible ones, often called 'dialects.' They are joined by a common writing system, which goes back to a classical script known as 'Wen-yen.' This script has no common pronunciation, but is read by each speaker in his or her particular dialect. The most prestigious variety of Chinese is the Mandarin, spoken in the north; this is known as 'Modern Standard Chinese,' and is based on the Peking (Beijing) dialect. There are two major systems of romanization: the Wade–Giles devised in 1859 by Sir Thomas Francis Wade; the present-day official Chinese romanization is known as 'Pin-yin' and was adopted in 1958. But the traditional characters persist.

Japanese is spoken in various dialects, but the Japanese adopted the characters of Chinese as their writing system in the early centuries CE. The characters are known as '*kanji*' and are still used, though restricted in number. Because of the entirely different structure of Japanese, an additional, more phonetic, system was devised, known as '*kana*.' This comes in two versions, the '*hiragana*' or 'common kana' used for grammatical particles, and '*katakana*' 'one-sided kana,' used for foreign loanwords. This cumbersome system has resisted all attempts at reform, though some changes have been made in a colloquial direction since 1880.

Korean was also first written in Chinese characters, but a native script was introduced in 1446. This

28-letter alphabet was devised by a group of scholars working at the behest of a reigning king, but did not win the recognition of the literati until the beginning of the twentieth century. Korean can be written in two ways in the late twentieth century, one which is purely alphabetic and one which is a 'mixed' script, including some Chinese characters. The former is used in North Korea, the latter in South Korea.

Arabic is a language whose classical form was established by the religion that bore it to triumph through North Africa and the Near and Middle East in the seventh and eighth centuries CE. It was used by Muslims through the Middle Ages and is still the language of the school and administration in all Arabic countries. There is a considerable gap between the often mutually unintelligible vernaculars that are derived from classical Arabic. Except in Malta, which has adopted Roman writing of the language, it is everywhere written in the Arabic alphabet. Both Arabic and Hebrew writing are descended from an alphabetic Phoenician script.

The major Indo-Aryan languages of North India are written in the Devanagari script or varieties of it, developed in the seventh to ninth centuries. It has remained essentially unaltered to the present. Varieties of it spread with Buddhism from India into other south Asiatic countries as far east as Malaya, Indonesia, and the Philippines. The languages have been standardized at various times.

4. Colonial and Missionary Efforts at Standardization

In Africa a number of lingua francas have developed to bridge the tremendous number of native vernaculars of the continent. Of these, Swahili is official in Tanzania and Kenya, and is used widely in East Africa. Others are Lingala, Fanakalo, and Sango. Hausa is used in Nigeria; Amharic is official in Ethiopia, Wolof in Senegal and Gambia, and Kongo near the Congo River. There are also countries where non-African languages are in common use, including Arabic, English, and French. The Island of Madagascar has a Malayo-Polynesian language.

Although the first grammar of an African language (Kongo) goes back to 1659, extensive study was not begun until the nineteenth century. Yoruba boasts the earliest dictionary written by a native speaker (1843). There has been intensive missionary activity, resulting in many local grammars, but there are few languages that can be described as standardized. In South Africa the formerly Dutch population uses Afrikaans, the English a variety of standard English.

American Indian languages are also numerous, with many local grammars and dictionaries, but little if any standardization. As in Africa, most such initiatives were taken by linguists. An interesting exception is the Cherokee syllabary, devised in 1821 by a half-Cherokee native named Sequoyah and widely used for a time. In Greenland the first book in the native Greenlandic was published by the Dano-Norwegian missionary Hans Egede in 1742. A systematic orthography in Roman letters was devised by the German missionary Samuel Kleinschmidt in 1851. But as a self-governing overseas administrative division of Denmark it has Danish as one of its official languages (along with Greenlandic).

As this brief survey of selected languages shows, standard languages are usually artifacts of religious or military penetration and the needs of a central government, abetted by an ever-expanding literate population.

Statistics: Principal Languages of the World (UNESCO)
J. M. Y. Simpson

In 1989 the Division of Statistics of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) undertook research—actually carried out on its behalf by the 'Groupe d'études de démographie appliquée' (GEDA)—into the numbers of speakers of the principal languages of the world, 'principal languages' being defined as those spoken by at least 100 million people or declared the official language in at least three countries. Relevant to this gathering of statistics is the status of each language in the countries in which it is used; consideration of this factor led to a typology of countries according to the

683

status enjoyed in them by the relevant principal language(s). This article is based on the publication of the results in 1992.

1. Speakers of the Languages

The question immediately arises of what degree of mastery of a language is required before a person can be said to qualify as a 'speaker' of that language. A distinction is drawn between 'real speakers' and 'potential speakers.' 'Real speakers' are defined as those who have a 'perfect command' of the language; this perfect command is acquired either because the language has been learned from childhood as a mother tongue or because it has been used as a medium of instruction during 'a number' (undefined) of years of compulsory schooling in that language. 'Potential speakers' are those who have experienced the language as a medium of instruction for 'fewer' years than real speakers or who have learned it as a taught subject in school or who have learned to use it as a lingua franca (see *Lingua Franca*). It is assumed that real speakers will be able both to speak and write the language, as will potential speakers who have experienced it as a medium of instruction or have learned it as a school subject.

Given the lack of statistics and the complexity of the task of compiling estimates of the above various types of speakers, the study did not take into account potential speakers who had learned to use the language as a lingua franca.

2. Status of the Languages

Three different statuses of language are recognized: official language, national language, and language of instruction.

2.1 Official Language

The official language is that which is 'used in the business of government—legislative, executive, and judicial.' In some countries the official language is specified in the constitution, the constitution itself being normally written in that language. With regard to official languages, countries can be grouped according to whether (a) they have escaped linguistic imperialism and exposure to imported languages or (b) whether at some time in their history a nonindigenous language was in use.

In the case of (a), i.e., countries that have 'naturally' officialized indigenous languages, the latter are the mother tongues of the great majority of their populations. Such countries may be officially monolingual or multilingual.

In the case of (b), i.e., countries where a foreign language has been present, three situations are recognized. First, one or more of the dominant indigenous languages may have been officialized; in this case again, the majority of the population will speak an official language as a mother tongue.

Second, the country may be officially bilingual, one official language being indigenous, the other non-indigenous and European. The nonindigenous language may be the mother tongue of a large sector of the population or it may be learned through the medium of education or 'in a specific linguistic context.' Third, a multilingual country may have officialized one or more foreign languages which is/are learned at school and used as medium(s) of instruction.

2.2 National Language

A national language is defined as 'the language of a political, social, and cultural entity'; all the languages of a country spoken as mother tongues have this status. The definition applies above all to officially multilingual states 'seeking to ensure equality for all nationalities through legal and constitutional provision enabling them to use their own language in contacts with the authorities.' 'In most countries without a colonial past, the national language(s) is/are the official language(s).' In countries with a colonial past which have officialized a foreign language, the indigenous languages may have the status of national languages. Sometimes national languages are defined as such in the constitution.

2.3 Language of Instruction

A language of instruction is a medium of primary, secondary, or higher education. It must of necessity be a written language. Its status as a language of instruction is normally set out in the legislation of the relevant Ministry of Education and sometimes also in the constitution. A language of instruction may be an official language as well as the mother tongue of all or part of the population. It may be indigenous or nonindigenous.

3. Scope of the Study

Given the above definition of 'principal language,' 12 languages qualify for investigation in the study: Arabic, Bengali, Chinese, English, French, German, Hindustani, Japanese, Malay–Indonesian, Portuguese, Russian, and Spanish. ('Bahasa Indonesia' and 'Bahasa Malaysia' are subsumed under the heading 'Malay–Indonesian' as being one language. Similarly 'Hindustani' is used as a cover term for Hindi, Urdu, and Panjabi. Arabic and Chinese are each treated as a single language.)

Calculations are made for the number of speakers of each language only in the countries in which they are in use as official languages, national languages, and languages of instruction. A relevant factor in clarifying the distinction between real and potential speakers is the status of the principal languages in the countries concerned. Real speakers are counted as being (a) those who speak the language as a mother tongue in countries where it is an official language or

a national language defined as such in the constitution; (b) those who have learned it (to the defined degree) through the education system in countries where it is an official language and/or a language of instruction; and (c) those who have learned it (to the defined degree) through the education system of officially multilingual countries where it is a compulsory subject. Potential speakers are counted as being (a) those who have learned the language (to the defined degree) through the education system in countries where it is the official language and/or the language of instruction and (b) those who have learned it (to the defined degree) in officially multilingual countries where it is a compulsory subject.

Not included in the statistics are (a) those who speak the language in question as a mother tongue in countries where it is neither an official language, nor a national language, nor a language of instruction; (b) those who have learned it as an optional taught subject; (c) those who have learned the rudiments of it 'in a favorable linguistic context.'

4. Country Typologies

The data required as an input are of both a qualitative and a quantitative nature. Qualitative information concerns (a) the status of the language(s) spoken in each country and (b) the organization of the education system. The latter is necessary for countries where the language of instruction is

nonindigenous in order to determine at what level or grade the language actually does become the medium of instruction. This information permits the computation for each country of the number of real and potential speakers. The quantitative information concerns (a) the number of mother tongue speakers and the population distribution by level of educational attainment and (b) the total school-going population and the number of repeaters by grade.

The requirements for calculating the number of real and potential speakers vary from country to country. They are determined by (a) the number of official and national languages; (b) whether an official language is indigenous or nonindigenous; and (c) the means by which a language is learned. On the basis of these criteria seven country typologies are established.

(1) Countries in which a single language is the official language: it may be indigenous or nonindigenous and is spoken as the mother tongue by at least 90 percent of the population. In all countries of this group except Pakistan, it is also the sole language of instruction (see Table 1).

(2) Countries in which several languages are official languages: they are indigenous and are learned either as a mother tongue or as a compulsorily taught subject. In such countries part of the population may be monolingual (see Table 2).

(3) Countries in which a single language is the official language: this language is nonindigenous and

Table 1. Countries in which a single indigenous or nonindigenous language is the official language and is spoken as the mother tongue by at least 90 percent of the population.

*Country with a high percentage of non-Arabic-speaking immigrant workers.

is spoken by less than 90 percent of the population. It is learned through the education system where it is a language of instruction (except in Guatemala where Spanish, the nonindigenous official language, is the mother tongue of part of the population; see Table 3).

(4) Countries in which the official languages are either non-indigenous or nonindigenous and indigenous. Consequently these are learned either as a mother tongue or through the education systems, for example Spanish in Paraguay and Peru, Hindustani in India, English in South Africa, Arabic in Chad and Mauritania, Chinese in Singapore, etc. (see Table 4).

(5) Countries with one indigenous language as the official language but with at the same time other widely spoken national languages. This is the case with Brunei, Indonesia, and Malaysia where the official language is the mother tongue of only part of the population while another part has to learn it through the education system (see Table 5).

(6) Countries in which one of the 12 languages under consideration is (a) either specified in the constitution as a national language or (b) is spoken by a large portion of the population as a mother tongue, though it is not recognized as an official or national language. To the first group belong Urdu in Pakistan, Bengali in India, and German in Belgium; to the second belong Chinese in Hong Kong, Macau, and Malaysia, and Spanish in Belize. Mauritius is a particular case where French, although widely spoken, is not an official language and is the mother tongue of only a small portion of the population (see Table 6).

Table 8. Speakers of the major languages in 1989.

Languages	Potential speakers	Real speakers	Total speakers	As percent of world population	Total pop. of countries concerned
Arabic	*	206,380,300	206,380,300	4.0	218,419,500
Bengali	*	177,609,100	177,609,100	3.4	948,429,800
Chinese	*	1,077,548,100	1,077,548,100	20.9	1,165,974,500
English	137,591,700	456,328,300	593,920,000	11.5	1,818,816,800
French	42,759,100	88,658,300	131,417,400	2.5	308,110,100
German	88,800	88,997,600	89,086,400	1.7	101,547,000
Hindustani	48,386,800	363,927,300	412,314,100	8.0	954,167,200
Japanese	*	122,846,200	122,846,200	2.4	122,846,200
Malay–Indonesian	49,441,700	63,852,200	113,293,900	2.2	197,612,000
Portuguese	2,629,500	158,447,900	161,076,200	3.1	184,517,200
Russian	*	285,077,900	285,077,900	5.5	285,077,900
Spanish	3,309,500	308,075,300	311,385,300	6.0	317,685,800

* All speakers of these languages are real speakers.

(7) Countries in which a nonofficial, nonindigenous language is used solely as a language of instruction and thus learned through the education system (see Table 7).

Tables 1–7 list according to the above typology all the countries in which are spoken one or more of the 12 languages investigated. Neither Japan nor the USSR (which existed as such at the time of the study) appear in the tables since they constitute yet a further category in that their official language is not widely disseminated in other countries as either an official language or a language of instruction. The information on which the typology was based was gained from various sources, such as the texts of constitutions, philologists, members of Embassies and Permanent Delegations to UNESCO, etc. Table 8 gives the numbers of potential speakers and real speakers of each of the 12 languages.

UNESCO July 1992 *Number of Speakers of the World's Principal Languages in* 1989. (Summary prepared by the Section of Statistics on Culture and Communication, Division of Statistics)

Verbal Hygiene
D. Cameron

It is a truism that linguistics is 'descriptive not prescriptive'—concerned to describe the structure and use of natural languages, and not to make value-judgements on them. *Verbal Hygiene* was the title of

a book that prompted debate among sociolinguists, by challenging the view that value judgements are of no relevance for linguistics (Cameron 1995). It argued that competent language users routinely make value judgements on language; ideas about what is 'good' and 'bad' in language are central to their understanding of it, and ought therefore to be of interest to linguists who study language use as a form of social behavior.

1. What is Verbal Hygiene?

The importance language users accord to value judgements is seen with particular clarity in practices of 'verbal hygiene,' i.e., active attempts to improve or 'clean up' language. These practices are many and varied. Examples include not only efforts to impose a standard dialect, pronunciation, or spelling, but also cases like plain-language movements or feminist campaigns to eliminate sexist language, language planning, and 'fringe' movements advocating whole-sale spelling reform, the abolition of copular verbs, or the adoption of artificial languages. What these instances have in common is not any single view of what is desirable in language use—the traditional grammarian and the feminist, for instance, will disagree on many points of detail. But they do share the more fundamental assumption that one way of using language may reasonably be preferred to another.

2. Verbal Hygiene and Prescriptivism

That assumption also underlies what linguists have traditionally called 'prescriptivism': how does 'verbal hygiene' differ? Cameron (1995: 3–11) sees the two concepts as overlapping but not coextensive. Her main reasons for wanting an alternative to 'pre-scriptivism' have to do with the meanings that term has acquired in linguists' usage. First, 'prescriptivism' is most closely identified with a particular subset of normative metalinguistic practices, those that focus on the value of *correctness* and equate 'correct' usage with adherence to the codified norms of a standard language variety. The term 'verbal hygiene' seeks to foreground the existence of normative metalinguistic practices, which intervene in language use in different ways and for different reasons, though they are equally animated by value judgements. Secondly, 'prescriptivism' in linguistics has acquired strong negative connotations: it is associated with ignor-ance, intolerance, and prejudice, and is usually represented as something extraneous to normal language use. Verbal hygiene, by contrast, is pre-sented as part of a more general metalinguistic function, which is integral to the workings of verbal communication:

> Because language-using is paradigmatically a social, public act, [it] must be carried on with reference to

norms, which may themselves become the subject of overt comment and debate. In our everyday interactions we take this for granted...without recourse to such ordinary metalinguistic practices as correcting slips of the tongue, asking what someone meant by something or disputing their usage of particular words, the enterprise of communication would be even more fraught with difficulty than it already is (Cameron 1995: 2).

From this point of view, it makes no sense to condemn linguistic normativity as such. Further, when one considers the full range of normative practices language users are engaged in, it becomes difficult to argue that they all exemplify ignorance (cf. language planning, a 'scientific' enterprise) and/or prejudice (cf. campaigns against sexist and racist language, which embody *resistance* to certain forms of prejudice). While verbal hygiene practices are never value-free, 'correctness' is not the only value that informs them. Others include esthetics (as in discussions of why one local accent is preferable to another); utility (as in arguments for official docu-ments to be written in plain language rather than obfuscatory jargon); and morality (as in debates on sexism and racism in language).

3. The Social/Symbolic Functions of Verbal Hygiene

Although verbal hygiene arises from a metalinguistic capacity which is indispensable for communication, in practice that capacity is used in ways that go well beyond immediate communicative needs—clearly we do not 'need' new spelling systems or arguments about how best to translate the Bible into Klingon (the invented language of a fictional alien species). Many verbal hygiene practices are better understood in terms of the social and symbolic purposes they serve for those engaged in them.

In some cases these purposes are broadly political: verbal hygiene is used to affirm a particular view of the ideal social order. This motivation is evident in conservative defences of standard languages, in feminist arguments for nonsexist language and the counterarguments of their opponents, in purist movements to purge languages of 'foreign' elements and in attempts to preserve or revive minority languages as symbols of ethnic or national identity. Professional and commercial interests (e.g., the interest of publishers in maintaining certain norms of written style) may also motivate verbal hygiene. And it can also be a form of 'language play' (Cook 2000)—this is probably its main function for Klingon enthusiasts, for instance.

4. Debates on Verbal Hygiene

Some linguists (e.g., Kalogjera 2000) have criticized verbal hygiene as a 'revisionist' concept that rehabi-litates reactionary forms of prescriptivism, under-mines the objectivity of scholarship, and encourages sociolinguists to politicize discussions of language

attitudes and linguistic change. In *Verbal Hygiene* (Cameron 1995: xi) it is noted that linguists can study normative practices without necessarily endorsing them. However, the book does challenge claims that linguistics itself is value free (the axiom 'all varieties are linguistically equal,' for instance, is not just a statement of what linguists believe to be true, but implicitly also a value judgement). If we accept that evaluation and verbal hygiene are integral parts of language-using, sociolinguists must engage in critical debates about the *grounds* for particular evaluations rather than denying the legitimacy of evaluation itself.

SECTION VIII

Language and Education

Applied Linguistics and Sociolinguistics

D. R. Preston

The relevance of sociolinguistics to second language acquisition (SLA) is twofold: First, it is concerned with the variation of language itself—the product, process, storage, and acquisition of such variation, including the variation learners acquire in a target language. That concern is surveyed in Sect. 1— Quantitative Microsociolinguistics. Second, it concerns itself with sociocultural and social psychological aspects of language, again including those involved in the acquisition and use of other languages. That concern is surveyed in Sect. 2.

1. Quantitative Microsociolinguistics

1.1 The Labovian Paradigm

A central claim of this approach is that the alternative forms of variable linguistic elements do not occur randomly. The frequency of their occurrences is predicted (a) by the shape and identity of the element itself and its linguistic context; (b) by the stylistic level of the interaction; and (c) by the social identities a relationships of the interlocutors.

The first attempt to apply this style of analysis to SLA data was very likely Dickerson (1974). Figure 1 shows the sensitivity of Japanese learners' pronunciations of English /r/ to the phonological environment. Before low vowels ($\_V_{lo}$), the pronunciation is fairly accurate (around 75 percent); before mid vowel ($\_V_{mid}$), however, it drops to around 45 percent accuracy, and before high vowels ($\_V_{hi}$), it is categorically wrong. The shape of variable /r/ in the Japanese learner's English is dramatically predicted by the phonological environment.

The predictability of the different realizations of a linguistic variable is often expressed in terms of a variable rule (see *Sociolinguistic Variation*), one aspect of which allows the degree of influence of each determining factor to be expressed as an independent probability. This style of analysis is used by Bayley (1990) to show the influence linguistic, stylistic, and social factors on Chinese learner's deletion of final t/d (in such clusters as *mist*, *left*, and *walked*). These probability scores are to be read as follows: those above 0.50 have a promoting effect on the rule; those below 0.50 have an inhibiting effect. (Here the rule is of t/d deletion; it could have as well been one of t/d retention, reversing the probabilities.) Like Dickerson's work, Bayley's shows that the following phonological environment is significant: vowels and pauses inhibit t/d deletion; consonants, liquids, and glides promote it.

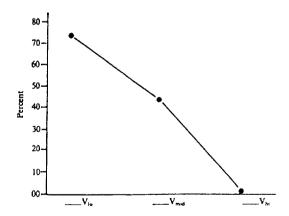
The stylistic dimension is also important in quantitative sociolinguistic work. The less monitored a performance, the more natural and governed by early-learned rules it will be. Labov (see *Labov, William*) refers to this stylistic level as the vernacular, and to the difficulties inherent in eliciting it in such potentially inhibiting settings as tape-recorded interviews as the 'observer's paradox' (see *Observer's Paradox*). Nonvernacular styles usually reveal not only a greater density of speech community prestige forms but also later-learned and less systematically applied rules (Labov 1972: 208–9).


Figure 1. Percentage of acceptable pronunciations of English /r/ in three environments by a Japanese learner (Fasold 1984: 250; adapted from Dickerson and Dickerson 1977: 20).

691

To tease out stylistic variety, sociolinguists have employed minimal pairs, word lists, reading passages, and techniques which promote various degrees of attention to speech in spontaneous talk. Table 1 shows Bayley's elicitation of the stylistic continuum at three points; his respondents read a set passage, recited a narrative (the story line of which was familiar to them), and engaged in spontaneous conversation. The least-monitored form of the language learners' performance ought to reveal the interlanguage vernacular, and, indeed, these respondents increase t/d deletion in their least-monitored style (0.67) and decrease it in their most heavily-monitored one (0.30).

The stylistic continuum is represented in several SLA accounts of learner variation. Krashen's monitor model, for example, Krashen 1987, turns the continuum into a two-way distinction, suggesting that a few, easily-represented rules are the result of conscious activity (learning) but that most rules, difficult to describe, are the result of nonconscious activity (acquisition). In performance, Krashen claims, learners do not have sufficient time to monitor the learned rules, and their systems fail. Native speaker studies, however, have been little concerned with the monitoring of overtly learned rules. Even the most carefully-monitored (or 'formal') end of the stylistic continuum results from the application of rules of which native speakers lack metalinguistic awareness. From this perspective, monitoring refers to general attention to speech, not to attempts to retrieve consciously formulated rules.

It is true, however, that native speakers, particularly in unfamiliar and/or status-ridden settings, may attempt to monitor ancient secondary school prescriptions or other shibboleths (e.g., *who* versus *whom*), and a relatively small number of such often socially damaging stereotypes exist in every speech community. Krashen may believe that an even greater number of rules have just such a status for the language learner. Since it is only dichotomous, however, the monitor theory provides no explicit account of variation within both learned and acquired sets of rules, nor does it appear to allow

learned items to permeate the area reserved for acquired ones.

In contrast, the continuous competence SLA model, for example, Tarone (1982), suggests that the stylistic continuum of the language acquirer operates much like that of the native speaker. The more attention the learner pays to speech, the more prestige forms are likely to occur (where prestige forms are construed to be target language forms or learners' understandings of what those forms are).

Tarone's characterization of what style is, however, borrows heavily from the operational devices used to elicit this dimension rather than from its underlying causes (e.g., degree of formality). Stylistic fluctuation, in her account, is due to the degree of monitoring or attention to form, and varying degrees of attention to form are by-products of the amount of time which various language tasks allow the language user for monitoring (e.g., writing perhaps the most, spontaneous conversation the least). This variation, however, all takes place for the language acquirer within only one envelope of performance or register; language learners, at least those in the early stages, are monoregistral. Only more advanced learners acquire different registers which entail such matters as genre and other complex norms of interaction and use which, in turn, contribute to the positioning of a task on the stylistic continuum.

Perhaps just some such distinction is at work in the data reported by Bayley in Table 1. The operational realization of the stylistic dimension is satisfactorily explained by the notion that greater monitoring leads to more target-like performance (presumably the retention of t/d/ in final clusters). Oddly, however, the respondents whose network associations show greater contact with native speakers also show an increase of t/d/ deletion (0.61). This apparent contradiction may be explained in the following way: the respondents with low network associations with native speakers have a single register of performance, something which might be called the learner register. In it, absolute t/d realization is the target norm, and t/d/ deletion is the learner vernacular. (The sources of the latter may include Chinese syllable structure, universal preferences for syllable structure, stage of learning, and other matters.) For them, the stylistic continuum is operationalized as tasks and is straightforwardly represented in their scores as those tasks allow them more or less monitoring time.

In contrast, the respondents with greater native speaker network contacts may have begun to acquire some of the complex registral factors which lie behind the continuum. In those registers which promote informality (where, presumably, less monitoring goes on), native speakers also delete t/d in final clusters. Superficially, all the respondents appear to be observing a rule that states that the more they monitor, the more they delete. The different network

Table 1. Word-final t/d deletion probabilities (in consonant clusters) in Chinese learner English (adapted from Bayley 1990: 8).

Following segment:	Vowel	0.40
	Pause	0.45
	Glide	0.55
	Consonant or liquid	0.60
Style:	Reading	0.30
	Elicited narrative	0.53
	Conversation	0.67
Social network:	Chinese	0.39
	Chinese and American	0.61

692

relations, however, suggest that different factors lie behind this performance. For the low network relations group, the stylistic continuum is driven only by the amount of time made available for monitoring by the linguistic task set. For the high network relations group, the continuum is indeed defined by the amount of attention given to a task but as determined both by the purely linguistic shape of the task and by the native-speaker-like registral considerations which contribute to the determination of a task's position on the continuum.

An apparent fly in the ointment of the stylistic continuum, however, emerges in such sets of data as those shown in Table 2. The third person singular indicative marker (3rs) follows the predictions made earlier—the more attention paid to form (obviously here the grammar test), the greater likelihood of native-like performance; but the article shows exactly the reverse trend—the greater attention paid to form, the less target-like the performance.

Preston (1989) suggests that this apparent contradiction may be explained by incorporating something of the monitoring distinction into the continuous competence model. The 3rs in English is clearly marked—it (and only it) of the present indicatives has phonological substance, and it is, except perhaps for its morphophonological adjustment, simple, controlled by the purely local concern of agreement. The article, on the other hand, is multifunctional, has alternative forms (including even null), and is driven by such non-local factors as presupposition, given-new information, and so on.

The 3rs, therefore, is the sort of form which monitoring will provide the right answer for, even if learners have come up with theories of their own rather than being explicitly taught. Rumination on what form (if any) of the article to use, however, is apparently more likely to lead to disaster than success. Its rules are complex and not guided by an immediate, simple context. Preston (1989) concludes that, in general, marked forms will make more rapid progress in the interlanguage development of more highly-monitored styles, and unmarked forms will more quickly develop in the unmonitored ones.

Native-speaker studies of variability were done at least in part to show how variation was central to linguistic change, and studies of respondents of

different age groups (studies in apparent time) rather than longitudinal ones have predominated. Only a few SLA studies have followed this lead; Young (1990), for example, shows that for Chinese learners of English the factor of low proficiency retards plural marking on nouns with a probability of 0.32 while the factor of high proficiency promotes plural marking with a probability of 0.60. SLA studies may, therefore, use quantitative methods to indicate the degree to which level of proficiency contributes to the predictability of target-like performance for a given feature.

1.2 The Dynamic Paradigm

The most noteworthy of the competing models in quantitative microsociolinguistics is associated with the work of Bailey, Bickerton (see *Bickerton, Derek*) and DeCamp (see *DeCamp, David*), particularly in its application to creole languages. Their work makes use of an implicational scale, which is sensitive to relations among variables in the entire system rather than to the set of determining influences on one variable.

The first application of such techniques to SLA is very likely Gatbonton (1978). Table 3 shows an implicational array of the voiced interdental (/ð/) for Canadian French learners of English. The controlling environments (here the preceding sound) are arranged on a scale of heaviest to lightest, but these weights are not only related to probabilistic influences of the various environments on the feature in question. The weight is an expression of the relation between one environment and all the others and the lect which that unique relationship defines. Lect 1, for example, is the grammar of learners who have not even begun to vary between non-native and target-like performances of /ð/ in the most likely phonological environment for target-like performance (i.e., after vowels). What is implicational about this arrangement is that every lighter environment also has, predictably, categorial non-target-like performance. Conversely, speakers of lect 11 who have invariant target-like performances in the lightest environment (i.e., the one least likely to promote such performance, here a preceding voiceless stop) predictably have it in every heavier environment. Such implicational arrays are apparently not arbitrary, for of the 28 respondents sampled in Gatbonton's study, only six did not fit one of the predicted lect patterns.

The dynamic paradigm approach is perhaps even more appropriate to semanto–syntactic and morphosyntactic variation, for the emerging lects are seen as ones which reveal redefined form–function units increasingly in line with target language norms. Huebner (1983), for example, in a year-long longitudinal analysis of an adult Hmong acquirer of English, shows, among other things, how *is(a)*

Table 2. VARBRUL probabilities for target-like realization of third singular indicative markers (3rs) and articles in English by Japanese and Arabic learners (Tarone 1985).

	3rs	Article
Japanese	0.63	0.42
Arabic	0.37	0.58
Grammar test	0.63	0.23
Interview	0.48	0.56
Narrative	0.39	0.72

Table 3. Implicational ordering of the acquisition of English /ð/ in five different environments by French Canadians (Preston 1989: 32, adapted from Gatbonton 1978).

	Linguistic environments					
	Heaviest				Lightest	Number of
Lect	V___	VCT___	VS___	VLCT___	VLS___	subjects N
1	1	1	1	1	1	3
2	1, 2	1	1	1	1	7
3	1, 2	1, 2	1	1	1	3
4	1, 2	1, 2	1, 2	1	1	0
5	1, 2	1, 2	1, 2	1, 2	1	2
6	1, 2	1, 2	1, 2	1, 2	1, 2	2
7	2	1, 2	1, 2	1, 2	1, 2	3
8	2	2	1, 2	1, 2	1, 2	1
9	2	2	2	1, 2	1, 2	1
10	2	2	2	2	1, 2	0
11	2	2	2	2	2	0

V___ = preceding vowel
VCT___ = preceding voiced continuant
VS___ = preceding voiced stop
VLCT___ = preceding voiceless continuant
VLS___ = preceding voiceless stop.
1 = categorical presence of nonnative substitute for English
2 = categorical presence of native or native-like English
1, 2 = variation of 1 and 2.

moves, in different environments, from marking asserted (or comment as opposed to topic) information to the range of functions which *is* has in the target language.

At first, there may appear to be only trivial differences between the Labovian and dynamic paradigms. The first studies the exact degree of influence of each factor; the second specifies the categorial states before and after variability and ignores the precise contribution of each controlling factor during variability, although the weight of each shows its relative effect. The psycholinguistic corollaries of the two modes are, however, quite distinct. The system which encloses the variety of probabilistic influences within the Labovian paradigm is a unified one. That is, variability, although clearly related to change, may also be relatively stable within the single competence of a monodialectal speaker. In short, variability is inherent. In the dynamic paradigm, any inherent variability is short-lived, lasting only during the brief transition between categorial presence and absence of form–function change (in a given environment). The greater variability which appears to be present is, in fact, simply the shifting back and forth from one lect to another. In short, most variability is apparent. The psycholinguistic ramifications of these two differing views have not been worked out in either native speaker or SLA contexts.

2. Language in its Social Context

The second group of general research trends surveyed here is represented by a variety of schools, the first three of which in particular are only briefly summarized.

2.1 The Ethnography of Communication

Closely associated with the American anthropological linguists Hymes (see *Hymes, Dell*) and Gumperz (see *Gumperz, John*), this style of sociolinguistic inquiry examines an array of contextual concerns in language performance, status, intent, reception, and the like. The targets of investigation typically include larger forms (e.g., genres, speech acts and events) as well as those investigated in quantitative styles, and the manner of investigation is more often qualitative. The results of such studies characterize the elements necessary to the communicative competence underlying appropriate speech behavior. Generally speaking, the influence of this area of sociolinguistic inquiry on SLA has been on the description of native-speaker behavior as a target model for speech acts (particularly in such culturally variable speech activities as warning, complimenting, requesting, and the like).

2.2 Ethnomethodology and Discourse Analysis

Discourse studies are associated with sociolinguistics, at least in part, due to the important contribution of such sociolingists as Garfinkel, Goffman (see *Goffman, Erving*), and Sacks (see *Sacks, Harvey*). In general, such studies hope to find a grammar of larger units, particularly the grammar that is created in the give-and-take of conversation. Like the ethnography of communication, discourse studies of

native-speaker interaction have been held up as models in SLA, although an important additional trend has been that of the study of classroom interaction, and those and other studies have focused on the conversational details of native–non-native and non-native–non-native interactions (see *Discourse*; *Spoken Language in the Classroom*).

2.3 The Sociology of Language

SLA studies have also been sensitive to the larger concerns of societal and individual bi- and multilingualism and to the concerns of language planning, minority languages, area linguistics, and emerging standards and varieties (see *Bilingualism, Individual*; *Bilingualism, Societal*).

2.4 The Social Psychology of Language

Language attitude studies have been related to SLA concerns from their beginnings, although early work in such studies by Lambert (see *Lambert, Wallace E.*) and Fishman (see *Fishman, Joshua*) focused on the affective domain in bilingual settings. Consideration of attitudinal factors (both towards and of acquirers) has been a component of many approaches to SLA. Krashen's monitor theory, for example, includes an affective filter which may impede or promote acquisition. Schumann's acculturation model (e.g., Schumann 1978) suggests that maximum or attenuated social distance between learners and members of the speech community they wish to join may result in a frozen, pidginized variety of the target (a dramatic form of fossilization). Gardner (1985) reviews SLA theories which contain strong social psychological elements or are themselves by-products of investigations into the social psychology of language.

Studies in this framework are generally quantitative, often experimental studies of affective responses to language samples. Some studies, however, focus on linguistic details and others on social factors. Such studies as Schumann's, for example, detail the pidginized forms of an unsuccessful language learner and suggest that the learner's rejection by and of the new language environment is a major factor. On the other hand, studies carried out in the tradition of Giles and his associates, following on earlier work by Lambert and Fishman, detail the attitudes toward native and target languages and their speakers by learners and hosts, and reason that language learning success or failure is related to positive or negative valuations, respectively, on both sides (see *Social Psychology*).

3. Trends and Prospects

The Labovian and dynamic paradigms are being brought together in such quantitative work as Bayley's and Young's, for probabilities are being assigned to underlying semanto-syntactic categories as they emerge in new varieties of a developing interlanguage. Perhaps such focus will provide insights into the important psycholinguistic differences between the two models of research.

For ethnographic and attitudinal studies, Preston (1989) has suggested that the development of an interlanguage (see *Interlanguage*) is best thought of as a process which will produce a competent bilingual, not one which will clone a native speaker. That understanding should allow even more careful investigation of the developing rule systems of an interlanguage, perhaps even singling out those subtle rule differences which effectively symbolize the non-native but successful speech community member. Speech communities are made up of speakers who share norms of communication, not necessarily of those who share the same native language. As interlanguages develop, it is logical to assume that learners are putting together a competent but distinctive system (open to quantitative analysis), which gives them a place in the speech community (or communities) where they intend to interact, such interaction being open to the various means available for the study of language in its social context. Both approaches will surely engage the interest of those who care to look at sociolinguistics in SLA settings.

Bilingual Education
M. E. Brisk

Bilingual education, using two or more languages as a medium of instruction, dates from 3000 BCE when scribes in the Mesopotamia were taught in both Sumerian and Akkadian. Most countries in the world offer bilingual programs in government funded and/or private schools. One of the languages is usually the national or official language (see *National Language/Official Language*) while the other language of instruction can be indigenous (Quechua in Perú), another official language (Arabic in Israel), regional (French in Canada), the language of immigrants (Finnish in Sweden), the language of guest workers (Moroccan in The Netherlands), an international language (English in Argentina), or the language of sojourners (Japanese in the United States).

The scope of bilingual education varies throughout the world. In a few countries bilingual education is universal in all schools. In Brunei, education takes place for all in both Standard Malay and in English. In most countries, however, bilingual education serves only a limited number of students. Such programs are the result of efforts of individual or experimental schools. The Foyer project administers five Dutch schools in Brussels serving immigrant children from Morocco, Italy, and Turkey. Students receive instruction in their native language and in Dutch. The use of Dutch increases as they move up the grades. They also take French which is compulsory for all students in Dutch schools.

Some bilingual programs address needs of multilingual student populations. In the United States, national and local legislation support bilingual education for diverse linguistic populations. Such programs serve only about a quarter of the students with limited proficiency in English and are designed to serve students for only a limited number of years.

Changes in the political history of a country are reflected in education policies. As a crown colony, Hong Kong traditionally had dual-system schools, English schools and Chinese schools where Chinese and English were taught as subjects respectively. Since 1997 all schools use Chinese as a medium of instruction in the elementary grades with English taught as a subject. English is the medium of instruction in high schools while Chinese language and history are subjects taught in Chinese.

When a language does not have a written form, bilingual education requires development of a writing system and materials in that language. In Africa, communities and linguists have teamed to promote experimental bilingual programs for the elementary grades using the community language. An alternative is the monoliterate approach to bilingual education in which students are taught orally in the home language while they acquire literacy in the other language.

1. Goals

The five major purposes of bilingual education are enrichment, maintenance, educational assistance, language revival, and serving transient populations. The acquisition of a second language is considered an educational asset. Bilingual education is designed to achieve second language fluency. Students in the Kato Gakuen elementary school in Japan receive instruction in English and Japanese beginning in kindergarten. Each language is employed equally through grade six.

Bilingual schooling is instrumental in language preservation. In a school in northern Arizona, Hualapai children are instructed in English and Hualapai throughout their elementary schooling. At the secondary level most of the instruction is in English with certain subjects taught in Hualapai.

Throughout the world children are socialized in languages other than the major language of education of the country. Bilingual education programs instruct students in their home language while they acquire the major or official language of the country. Eventually, students are integrated into the educational system in the national language. In Guatemala, the *Programa Nacional de Educación Bilingüe* (PRONEBI) provides bilingual education to

Mayan populations in their home language and in Spanish.

Bilingual education also is employed to revive languages. Such is the case of Basque in Spain. Since the 1970s the promotion of Basque through education has helped not only strengthen Basque among Basque people but has made Spanish speakers living in the Basque region conversant in Basque. Parents in this area of Spain may opt to send children to Spanish, Basque, or bilingual Spanish/Basque schools.

Since families of government or multinational employees move frequently, bilingual schools are created to facilitate their language needs and provide some continuity in the education. The central schools in India for families employed by the central government who move around the country offer instruction in the sciences in English and in the humanities in Hindi. Students' mother tongues are taught as a subject. There are a number of European schools created to serve civil servants working with the European Union organizations. Where there is space, local or immigrant students are also included. These schools have subsections for several of the languages of the member states where instruction takes place in the native language of the subgroup of students and another of the member state languages. Third or fourth languages are commonly taught as subjects.

2. Program Models

There are four major types of bilingual programs: dual language; language switch; Canadian Immersion; and transitional bilingual education. Dual language programs use two languages throughout schooling. In language-switch models instruction takes place in one language for some grades, while a different language is used for the remainder of the grades. Canadian Immersion programs start schooling in the children's second language, introducing the home language gradually although instruction continues in the second language. Transitional programs use the native language of the students for a short period as a bridge to learn the second language.

Programs differ greatly depending on their language outcomes, target population, and use of the two languages. Unplanned variation results from teachers', beliefs and level of language proficiency. Although a model may call for the use of one language, some teachers instruct mostly in the other because they believe it is more important or because they are more fluent and comfortable in it.

In dual-language models, which aim at additive bilingualism, (see *Bilingualism, Societal*) students develop two languages. Dual-language programs vary depending on the type of population they serve. Usually students begin school knowing at least one of the languages of instruction. Occasionally a small percentage of students are native speakers of a different language. Private schools catering to elites often feature a bilingual curriculum as in Argentina where the Spanish curriculum meets requirements of the Ministry of Education while instruction in English, French, or German conforms to standard curricula of those countries. An increasing number of programs in the United States attract English speakers as well as speakers of other languages. Two-way programs, as they are called, instruct students in both English and in the other language. The presence of native speakers of both languages is considered an asset for second language development.

Language maintenance (see *Language Maintenance, Shift, and Death*) is another type of dual-language program where language minority populations are schooled in their home and national languages. Navajo students in selected reservation schools in the United States receive instruction in Navajo and English throughout their elementary school. At the secondary level, subjects related to the Navajo culture are taught in that language. Some ethnic schools, initiated by ethnic communities or religious organizations, feature bilingual curricula. Such schools fulfill educational requirements of the country as well as the community's need to maintain their language and culture.

The distribution of the two languages in the curriculum of the various types of dual-language programs varies. Languages may be equally balanced by teaching half a day in each language or alternating days or weeks in each language. In some schools languages are used for specific subjects. In bilingual schools for the deaf both languages are used all the time since the sign language serves face-to-face communication and another is used for reading and writing.

Some countries promote bilingualism by switching the language of instruction after a few grades. To prepare students for the switch, the language is first taught as a subject. In Luxembourg the language is switched not once but twice. Most children arrive in school monolingual in Luxemburger, the language of initial schooling. Instruction gradually changes to German with French taught as a subject and by high school it gradually changes to French.

French immersion programs were developed in Canada to promote bilingualism among English speakers. In the early immersion version of the model, students are introduced to schooling in French, their second language. French remains the only language of instruction for about three years. English, the home language, is then slowly introduced until it occupies 70 percent of instruction time by the secondary grades. Late immersion models start students in English with French taught as a subject. Towards the end of elementary school, French becomes the only language of instruction

for two years. English is gradually reintroduced. The early immersion model has been adopted by other countries using other languages for immersion, always aiming at the dominant language population.

Transitional programs prevail where bilingual education aims at assisting students who do not speak the official or national language in which most schooling occurs. The language outcome is subtractive bilingualism because students learn a second language but lose or do not develop their home language. Students are instructed in their home language for a limited time while they develop proficiency in the official language. In England, programs for Punjabi students last one year, Turkish and Moroccan students can attend transitional programs in The Netherlands for two years, while Sweden offers four-year programs. These programs are directed to some of the students who are in special classes until they are ready to join students whose entire instruction is in the official or national language. Some schools attempt to integrate students. In Norway, bilingual instruction directed to Turkish, Urdu, and Vietnamese speakers takes place in classrooms that include Norwegian speaking students. A team-teaching approach is used where one teacher instructs both groups in Norwegian and the other teacher helps immigrant students in the content areas using their native language.

3. Other Education Models for Language Development

Programs that seek to develop fluency in two languages, a second language, or the students' home language are often labeled bilingual education. They are not strictly speaking bilingual since instruction takes place in one language while the other is taught as a subject. In other cases instruction takes place in students' second language. The students become bilingual but the program is monolingual. Yet other programs offer special classes in the mother tongue of language minority students. Communities seek to maintain their children's bilingualism by creating ethnic schools or programs that run on weekends or after school where the home language is taught. Local governments, religious institutions, or foreign governments support these programs. The attendance is voluntary for as long as parents wish to send their children to these programs.

Language programs emanate from a desire for bilingualism, the need to recognize various linguistic groups, educational assistance, language revival, and service to transient populations. Bilingualism is a necessity in Brussels where Dutch schools require French classes for Flemish students and French schools have compulsory Dutch classes. Several linguistic groups may overlap in one country. While each group uses its language for instruction in the school, the language of the other group is offered as a compulsory or elective subject. In Finland parents may choose to send their children to schools that instruct either in Finnish with Swedish taught as a subject or schools that instruct in Swedish with Finnish as a subject. Many countries offer special second language classes to assist students who do not speak the school language. Throughout the United States, school districts offer English as a Second Language to large numbers of immigrant and other home language students. Rather than bilingual schools, some movements to revitalize languages (see *Endangered Languages*; *Reversing Language Shift*) have called for total immersion in the language. Such is the case of Catalan immersion schools in Spain where instruction takes place in Catalan and Spanish is taught as a subject. The same approach is followed in the Gaelscoils in Ireland where instruction takes place in Irish with English taught as a subject.

In international schools which serve transient populations, English is usually the language of instruction while the language of the country as well as other languages are taught as subjects. In the Vienna International School, German is a compulsory subject and a third language is optional. Mother-tongue instruction is encouraged but the parents must pay for it.

4. Debate Over Language Use in Education

The paradox of bilingual education is that when it is employed in private schools for the children of elites it is accepted as educationally valid, but when it becomes a matter of public policy, bilingual education stirs controversy. This debate over choice of language for instruction is the result of universal education. In the past, education was the perquisite of a few. Knowledge of several languages was an important component of education. With the advent of education for all, language use in schools became associated with rights of native speakers of those languages. The use of languages in education became an issue connected with political, economic, and social agendas far removed from the simple notion that bilingualism is the mark of an educated individual.

The need to consider language in education emerges from the presence of indigenous groups that speak diverse languages, the influx of people of other languages and cultures who enter a country as immigrants, guest workers, or refugees, and/or the changes in political boundaries. African countries that adopted European languages after independence as their official language confronted a dilemma: how to educate a population that speaks a variety of languages which often do not include the official language. Similar concerns are present in Australia, the United States, and certain countries in Latin America, such as Mexico and Perú, toward their

indigenous populations. Many European countries, Australia, and the United States are destinations of immigrant, guest workers, or refugee populations. These countries have crafted educational policies to address the presence of a multilingual population in their schools.

Changes in the language of education have followed historical events such as the dissolution of the Soviet Union and the retreat of colonial powers in Asia. The rise in power of local groups has created drastic changes in language choice for schooling. Upon the formation of the federation of Malaysia in 1957, the educational policy allowed for Malay, Tamil, Chinese, and English medium schools for the elementary level and Malay and English for the secondary level. The increase in power of local people has translated into education being principally in Malay with some concessions for other languages.

A pioneering study conducted by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1953 revealed that children educated in their second language experienced difficulties in school. The report of experts from around the world, sponsored by UNESCO, declares that the home language is the best initial medium of instruction because it relates to the child's culture, facilitates literacy development and learning of different subjects, and promotes understanding between the home and the school. The report also underscores the importance of teaching language minority students their national language as a second language by gradually introducing it in elementary schools to prepare students for further education.

Many educators and linguists today echo UNESCO's recommendations. Yet others still adamantly oppose instruction through the native languages and believe that intense instruction in the national or official language is the best route to educational success. Emotional and pragmatic reasons abound in these debates on choice of language for education. Arguments often ignore educational principles due to political, economic, social, cultural, linguistic, and psychological pressures. Support for specific languages for instruction derives from notions of national identity and recognition of ethnic groups. The cost of implementing such programs and the practicality of teaching certain languages concern many politicians and administrators while the economic advantages of knowing certain languages persuades others. The social status of languages influences the desirability of including them in schooling. Cultural and linguistic diversity appeals to some and concerns others. The formation of identity and the development of positive attitudes toward languages and their speakers are considered essential by some, while others do not believe it is the task of schools but the duty of families and community organizations.

Many nations have developed educational plans to address the role of languages in education. The scope of these policies varies. Australia's 1987 National Policy on Languages strives for language maintenance of immigrant and aboriginal languages. In contrast, Danish official guidelines for teaching language minorities (*Undervisningsministeriet* 1984) focus on providing for rapid adjustment to instruction in Danish. Regardless of how progressive or limited the policies are, governments have been slow in implementing such plans. In order to succeed, measures that require use of minority languages in education must include support for materials development and teacher preparation. The government of Nepal, pressured by minority language groups and linguistic human rights activists, retreated from its Nepali-only educational policy to allow language minority communities to establish native language primary schools. There has been no visible effort from the government to implement such measures. In Nepal, as in many other nations with other pressing concerns, the preservation or utilization of minority languages in education is not a high priority.

Much of the rhetoric about use of languages in education eludes the principal goal of schools which is to develop knowledgable, thoughtful, and well adjusted individuals. Use of the home language and culture of children has a role in such development. In the present world, knowledge of more than one language is also an educational asset. To achieve such goals it is more important to focus on the quality of schools and instruction than to protect particular languages. Bilingual education research illustrates the features of schools, curricula, instruction, and assessment instrumental in successful education. Knowledge of this research supported by the will to implement its recommendations is a promising formula for quality bilingual schooling.

Black English in Education: UK

M. Dalphinis

Although Black English has a longer history as a language of trade and initial contact between Africans and speakers of English on the West African coast from at least 1600, Black English in the UK is the result of the linguistic change from Creole (see *Pidgins and Creoles: An Overview*) languages spoken by older Afro–Caribbean immigrants into the UK which, under the impact of English as the dominant language in the UK have become a more English-like means of communication for the UK-born descendants of these former immigrants.

1. Linguistic Changes

Creole languages in the UK have undergone a process of linguistic change to become Black English: this is similar to the way in which Creoles have changed to Black American speech, in the USA (see *Ebonics and African American Vernacular English*).

These changes have a number of phonological, grammatical, and syntactic features. Phonologically, Creoles are being replaced by largely white working-class English linguistic features, as the latter are the group the Creole speakers have had most sustained contacts with in the UK. For example, the use of ʔ, in *ju wo me*ʔ ('You what mate'), in Black English, represents a clear Cockney influence. Similarly, Jamaican Creole *kyã* ('can't') is pronounced *kã*, under the influence of English 'can't,' by speakers of Black English.

Creole grammatical features in Black English have been retained at a mainly unconscious level of linguistic control, for example, in saying 'John go to market,' when the speaker wants to say (at a conscious level) 'John goes to the market'; this reflects the Creole uninflected verb, *John go makit.* Similarly the phrase *migwann mi ducks* ('I'm on my way, ducks'), reflects a continuation of Creole grammatical structures but with the use of the working-class English loan word 'ducks' (meaning 'dear').

Other grammatical features include the use of Adjectival Verbs, for example, *red* in *it red* instead of English 'It is red.' A major grammatical feature of Black English is the mixed use of both English and Creole grammatical features, for example, *di walls dem*—'the walls' in which both the English plural and Black English plural forms are included.

At the semantic level, Creole concepts have entered into English, for example, English 'wicked' has been extended to include the Creole meaning of 'very good.' The general trend is from Creole to Black English to English. However, Creoles of French vocabulary have not interfaced with English, and instead are involved in the general shift to Jamaican Creole by Black youth irrespective of island origin.

2. Creole Features and Black English

To clarify the differences between Black English and Creole both in the Caribbean and in the UK there is the general recognition by linguists of a basilect (see *Pidgins and Creoles: Models*) of core Creole sentences which contrast with an acrolect/mesolect of Black

English sentences. In this acrolect the majority of the speaker's repertoire consists of English sentences, with an admixture of Creole core sentences.

Some writers also point to degrees of fluency of the speakers in Creole/Black English as another distinguishing factor. Implicit in this factor is the view that Black English is a transitional position between Creole and English. Consequently, its speakers use Creole grammatical features, usually at an unconscious level, while at a conscious level, they use phonetic and semantic features of English, with Creole interjections for particular social effects.

3. Education

The UK context has been one of initially deeply held racist views about Creole speakers and the type and amount of education needed by them. Within this social context, the following main historical trends can be identified in relation to Creole and Black English in UK education.

(a) Eradicate Creole/Black English in the classroom.
(b) Assimilate Creole/Black English in the classroom.
(c) Tolerate Creole/Black English in the classroom.
(d) Accept linguistic pluralism within the overall uniformity of the UK National Curriculum.

These changes are often related to varying emphases in political thinking, as well as changes in the ideologies about teaching and learning. For example, teacher motivation to 'eradicate' Creole in the 1960s was tied up with the then popular learning theory based on the behaviorist stimulus/response ideas of Skinner. This view saw the Creoles as part of 'bad' linguistic behavior which had to be corrected or changed in order that English or 'good' linguistic behavior could emerge.

This corrective view was also linked with many Afro–Caribbeans being put into schools for the educationally subnormal, because their linguistic performance was seen as an aspect of linguistic and cognitive inferiority. The eradication view was followed by assimilationist educational perspectives in the 1980s which were characterized by a wish to ensure that a great deal of English culture was 'soaked up' by the children of Afro–Caribbean immigrants. This, indeed, led to one or two local authorities bussing their Afro–Caribbean pupils around the Local Education Authority so that they did not become too 'contaminated' by their own culture and languages. Later educational perspectives in the 1990s, when ideas of linguistic varieties and repertoires were popular, encouraged a greater tolerance of Creole and Black English, which were used in some London schools as part of linguistic and literacy studies.

Within the National Curriculum documents, Creoles are mainly discussed under the English recommendations from the following perspectives, which would apply inter alia to Black English:

(a) providing information on the spread of English internationally;
(b) information about linguistic change;
(c) information about comparing languages;
(d) information about Creoles;
(e) the use of Creole/Black English as part of class exemplification;
(f) as part of a generally assimilationist process, from Creole to Black English to English.

The Kingman Committee Report on English, indeed, highlights Creole as a language which, amongst others, has enriched English. It highlights similarities between English, Black English and English Creole vocabulary while downplaying syntactic differences.

Black parents have seen standard English, rightly, as the key to access to education in an English-speaking society and have, generally, had expectations of high educational achievement for their children. These expectations were well supported in the Caribbean by both the educational outcomes and the high expectations of Caribbean teachers with regards to their pupils. However, in the UK this traditional Caribbean expectation has been questioned by both the lower educational achievements of pupils of Caribbean origins and in the expectations of UK teachers, for example, as described by Stone (1981) and Coard (1971).

4. Accommodation in the National Curriculum Perspective

In order to accommodate demands by Black parents in addressing the cultural needs of their children, a number of educational texts by Black authors have become part of the National Curriculum, for example, stories by P. Breinberg in the book list for the National Curriculum reading profile component.

The general theme of accommodation is one in which many aspects of Black English culture and language(s) can easily be investigated to fulfill a number of National Curriculum requirements in English, particularly in the area of speaking and listening. However, these are highly dependent upon the skill, interest, and cultural repertoires of the teacher.

Similarly, with standardized assessments in relation to mathematics and science, there is no ruling against the use of mother tongues, including Black English, in the presentation of the mathematical and scientific skills of the pupils.

However, in the same way that the Community Languages which can form part of the schedule of 'foreign' languages taught in the National Curriculum are prescribed (these include Greek and Chinese,

but exclude Turkish), so too are the narrow terms within which Creole and Black English are considered in the UK National Curriculum.

While it could be claimed that the National Curriculum implies that Creole/Black English is part of the general bilingual heritage of Afro–Caribbean pupils, it is clear that Creole is described as a 'dialect of English,' although with an 'apology':

> ... The term 'dialect of English' which we have just used is itself problematic. Whether Creole varieties are termed 'dialects of' English or regarded as languages in their own right is a political and ideological question, which concerns the social identity of groups of speakers in UK society. It is not a matter which has a simple linguistic definition.
> (Department of Education and Science 1989 4.9)

The issue is how to assimilate an ex-slave population within the wider 'English' family while forgetting that some Caribbean Creoles are derived from French vocabulary. Indeed while accepting linguistic variety, both the Kingman and the Cox Reports focus upon the centrality of English (as was their remit) and see Black English/Creole only as a means of illustrating the international dimensions of English within an overall assimilationist process.

5. Culture and Identity

Issues of identity and of attitudes towards Creole and Black English, remain the areas that lack the attention of educational researchers in the UK. Historical factors have had important influences on these issues. The identity of Creole speakers in the UK, for example, is tied up with UK nationalist attitudes, which do not foster the educational development of an Afro–Caribbean identity, but which suggest that convergence towards a single 'UK' culture is desirable. Black English speakers, therefore, often relate to Creole/Black English as a symbol of identity in the face of monolithic 'UK' racism, irrespective of any high degree of fluency in Creole by the speakers concerned.

Attitudes to Black English by Black English speakers themselves have often been negative, particularly as far as older Creole speakers are concerned. The latter often saw Creole as a barrier to the economic advancement of their children. This has meant that discussing anything to do with Creole in the UK educational system has always begun on the difficult ground of negative parental attitudes towards any such discussion by teachers, who the parents thought were using another strategy to educationally oppress their children, as had been done in relation to issues of educational subnormality previously. Speakers of Black English, therefore, often have the ambivalent background of a negative stereotype of their parents, while wanting to preserve

Black English as one of the few manifestations of their differences from a White UK society which they perceive as racist. Black English, therefore, becomes a retreat for Black English pupils who want to restrict contacts with a White society which has proved to be hostile.

Oral literature in Creole remains a productive aspect of Black English and Creole culture, as many Afro–Caribbean poets in the UK use it as a medium, for example, L. K. Johnson and M. Collins. Closely related to the medium of such literary works is the strong African musical tradition which, in Reggae and other Afro–Caribbean music, uses Black English/Creole as an essential cornerstone of its communication. Dub poetry and disc jockey verbal communication in more recent times are also a dimension of African oral art which, although it may not use Creole in its surface structure, is very reliant on Black American speech, which like Black English, is itself on a continuum from a previous Black American Creole.

The question which needs to be asked is what is to be the destiny of Black English in the UK, in the light of previous Black American Creole experiences. Given the much smaller size of the Afro–Caribbean population in the UK than in the USA, the trend of linguistic assimilation into native British varieties may be more profound.

Racial difference will remain accentuated. Africans have, however, always changed the cultures they found themselves in, in order to express their own consciously and unconsciously held beliefs. That trend seems likely also to continue, not least in the area of language.

6. Conclusion

The English National Curriculum accommodates the possibility of Creole usage but politically implies that the usage must be in an assimilationist cause, by relating the Black English/Creole mother tongue to UK English. The culture of young Afro–Caribbeans however, caught in the contradictions of racism, the search for sheer survival and maintenance of a sense of identity, is giving rise to other dimensions of Black English/Creole linguistic development in the UK.

Child Language: An Overview
S. Strömqvist

The study of child language is first and foremost a window on the developmental process by which individual children acquire a language—whether spoken, signed, or written—in interaction with their environment. Children's language acquisition is situated in a cognitive and a sociocultural context, and the structure of development is shaped by biologically given information-processing capacities and constraints in interaction with the structure of the particular input to the child. All normally developing children are known to follow a similar overall structure of development with lexical and grammatical spurts typically occurring between roughly one-and-a-half and three years of age. At the same time, children's sensitivity to their linguistic environment leads to certain language-particular marks on their developmental profile from very early on.

Some aspects of language, such as pronunciation skills or a basic grammar, are to a large extent already acquired at a relatively early stage of development. Other aspects of what you know when you know a language continue to develop beyond childhood. For example, there is a continuing growth of lexical knowledge and of rhetorical (e.g., narrative, expository, etc.) abilities in adolescent and adult language users. Indeed, language acquisition is an open-ended process and there is neither any perfectly steady state nor any stage of completeness in the linguistic career of a normal human being.

1. Towards a Theory of Child Language Development

The definition of language acquisition as the process by which learners develop a language in interaction with their environment yields five broad concepts or theoretical terms: 'learner,' 'environment,' 'interaction,' 'language,' and 'development.' A comprehensive theory of child language development should integrate and provide a deeper understanding of these terms. To put this somewhat differently, a theory of child language development presupposes theories of what a learner is, the nature of the interaction between the learner and his or her environment, what it takes for something to be a 'language' or constitute knowledge of language, and how the structure of knowledge and skills acquired—as well as the acquisition process itself—change over time (development).

Although there is consensus in the scientific community that a number of factors associated with the above five concepts interact to shape language development in the child, there is no consensus about the exact nature or the relative weight of these factors. Some researchers assume that syntax is the most central aspect of language and that the learner is biologically endowed with crosslinguistically valid knowledge of language ('universal grammar'). According to this theoretical position, the child's input plays a passive role, in that it merely triggers the assumedly innate brain program to work out the central syntactic constraints of the linguistic environment. Indeed, the input to the child is seen as containing a lot of noise, possibly distracting the child from discovering the underlying constraints and regularities of language. Because of this 'poverty of the stimulus,' the argument goes, the child has to be genetically endowed with sufficient knowledge of language in order to be able to acquire language all the same. Further, a consequence of this position is that those aspects of language which are considered to be most important can be said to be fully acquired well before the end of the preschool period—see, for example, Pinker (1996).

Other researchers hold that the central thing about language is the communication of meaning, a position which foregrounds semantic and pragmatic aspects of language, and that language acquisition is not merely the felicitous acquisition of lexical and syntactic forms, but the mapping of these forms onto meanings and communicative functions. According to this view, important parts of language development can be modeled in terms of reorganizations of the mental representations in the learner or, more precisely, reorganizations of the relation between linguistic forms and functions/content. These reorganizational processes are driven both by principles of human information processing (such as principles of clarity, economy, etc.) and by external factors (the input and the learner's adaptation to language usage in new sociocultural contexts), and they characterize the language user not only in childhood but also in adolescence and adulthood. See, for example, Ninio and Snow (1996), Berman and Slobin (1994).

Further, the nature of the biologically given propensity for language learning need not be in the form of inborn knowledge or information. According to the so-called connectionist view, the information-processing capacities emerging from the neural architecture of the brain provide the prime explanation for children's ability to build language on the basis of linguistic input—see, for example, Elman et al. (1997). The interaction between learners and their environment is at the core of this approach, as it is in approaches focusing on pragmatic aspects of language. The input is assumed to play an active, formatting role, in children's acquisition of language.

The variablity and contextual distribution of bits and pieces of language in the input tend to be seen not as noise but as a rich source of information which children can use to discover what these bits and pieces are and how they are used for communication.

A particularly elucidating approach to the role of the input is the crosslinguistic study of language acquisition—see, for example, Slobin (1985–97). Comparisons of child language development across languages which display similarities and differences have helped articulate ways in which diversity of input can effect diversity of acquisition structure. The rapidly growing use of computer technologies in the international research community for sharing and analyzing child language data has greatly facilitated crosslinguistic comparisons (see MacWhinney 1991).

2. The Beginnings of Language in Infancy

Perception experiments using so-called habituation techniques (e.g., the head turning paradigm) show that at around six months of age infants have begun to tune in to their ambient linguistic soundscape. For example, they perform better at discrimination tasks involving sound contrasts that occur frequently in their ambient language; or, they prefer familiar sounds to unfamiliar ones in preferential tasks. The differences between the sounds used in the experiments can be subtle. For example, infants growing up with American English prefer to listen to a [y] typical of American English as distinct from a [y] typical of Swedish. The emerging representations of speech sounds in the infant at this early stage are nothing like proper linguistic representations in the sense that they would be used for contrasting one word form from another. They are, however, an important first step, which, under normal circumstances, will clearly influence the further course of development. A few months later, towards the end of their first year, infants begin to display phonetic qualities of their ambient language in their own babbling. For example, Swedish infants have been shown to babble with a more dental articulation than American English infants, who are distinguished by a more alveolar babbling.

Around the beginning of the second half of their first year, infants typically begin to show signs of having formed mental representations of objects, that is, representations they can to some extent retrieve at will. For example, contingent upon having dropped an object so that it is temporarily out of sight, they can start searching for it. This landmark of cognitive development, known as 'object permanence,' is a precondition to the learning of words. Words typically begin to emerge in children's communicative development around one year of age, at roughly the same time as most children start to walk. Object permanence is also a precondition to 'peek-a-boo' (suddenly hiding, for example, a hand puppet and

then suddenly making it reappear), a game which is played with small children across many different cultures of the world.

The learning of words and other meaningful units involves ferreting out units of the input speech-stream (the 'segmentation task') and mapping these units/forms onto concepts/functions (the 'mapping task'). The child's job of solving these tasks is determined by a number of different, interacting factors.

In spoken language certain parts of an utterance tend to be prosodically foregrounded (by means of stress, pitch, and/or duration), and others tend to be backgrounded. In child-directed adult speech, these differentiations are often exaggerated as compared to adult-directed adult speech. The exaggerated contour increases the perceptual salience of the foregrounded items even more and thereby serves as a spotlight guiding a child to direct his or her attentional resources to selected parts of the speech stream. This kind of spotlight hits first and foremost content words, to a limited extent function words, and to no or almost no extent affixes. A segmentation strategy based on prosodic spotlight would thus yield a predominance of content words in the child's earliest vocabulary, a prediction which turns out to be correct.

The child's early encounters with language take place in face-to-face interaction, a setting which provides the interactants with a shared perceptual space and the possibility of online feedback and mutual adaptation. In this kind of setting, content words (*car, teddy, fall (down)*, etc.) and deictic words (*there, that one, this*, etc.) are relatively easy to grasp for the early word learner not only because of their perceptual salience but also because their meaning can be demonstrated or exemplified by reference to objects, relations, and events in the shared perceptual space. Gestures (importantly pointing) and gaze accompanying speech further tend to facilitate the child's mapping task in that they help in securing joint attention to the object or event referred to or commented upon.

In their so-called 'sensorimotor' development, prelinguistic infants manipulate objects in the physical environment, making something fall, putting an object into or taking it out of a container, using force to remove something which is stuck, etc. In this way children are gathering experiences from manipulative motion scenarios in which they themselves are often the causal agent. Children thereby come to shape concepts of various types of objects, or spatial relations (e.g., containment, support, tightness of fit, or direction up, down, in, or out), of causality, and of different types of motion events. Since many of these concepts are precocious in the sense that they develop before children start to acquire words, they might facilitate children's mapping task insofar as

they present themselves as candidates for concepts that can be encoded into a linguistic form.

Precocious interactional activities may provide a frame of understanding for novel words and constructions. For example, extending the peek-a-boo game with speech acts (such as *Where did he go?*, *Where is he?*, *There he is again!*), make these speech acts easier for the child to understand than if they were encountered in an equally novel activity type.

For further details, see Clark and Clark (1977), Morgan and Demuth (1996).

3. Vocabulary Development and Grammar in Early Childhood

3.1 *The Vocabulary Spurt, Analysis, and Inflectional Morphemes*

A child's build-up of the first 25–50 words proceeds slowly, but then there is typically a steep increase in lexical growth rate, the so-called 'vocabulary spurt.' On average, the vocabulary spurt starts towards the end of a child's second year of life. Exceptionally early word learners start their spurt at the beginning of their second year, and slow ones towards the end of their third year.

As to their sound shape, the early word forms in children's language development can have many different relations to the adult target forms. Occasionally, children can hit the target in strikingly accurate fashion, something that might suggest a holistic imitation strategy on the part of the child. Often, however, children's productions are simplified in comparison to the adult targets, suggesting that they have performed some sort of analysis of their input. For example, given the target word *crocodile*, some children would focus on and expend their effort of analysis on its multisyllabic quality, whereas others would focus on the stressed syllable only. The former focus of analysis would typically be at the expense of the details internal to the syllables, resulting in, for example, a form of pronunciation like [kokoko]. The latter focus would typically allow for a greater resolution of segmental details, resulting in, for example, [dajl].

The study of phases of analysis and reorganizational processes is at the core of child language research. Already diary studies contain ample evidence and exemplification of this phenomenon. Consider the following four developmental sequences for the sake of illustration.

The first sequence is indicative of reorganizational processes in the child's phonological representations of the word *pretty*: (a) [prətɪ] → (b) [bɪdɪ] → (c) [prətɪ]. Because of the initial (a) and final (c) similarity with the target form and the medial (b) dip (phase of deviance), this developmental pattern is often described as 'U-shaped.' The dip is revealing of some kind of generalization and top-down processing, resulting in an observable linguistic product

which deviates from the target standard. And the developmental move from (b) (deviation) to (c) (target form) represents a reanalysis or adjustment to conform with the adult target. In the developmental sequence just quoted children can be hypothesized to have first learned the form [prətɪ] as an unanalyzed whole ('rote-learning'), whereas in the second phase they have reorganized their representation of the word in terms of its internal segmental structure. If the task was to learn in total, say, only 100 words, it might not be economical to expend cognitive efforts on analysis; rote-learning would suffice. Conversely, the rapidly growing number of words following the start of the vocabulary spurt pushes children to reorganize the principles for encoding, storing, and retrieving word forms.

The second and third illustrations concern children's development of inflectional morphology. The second developmental sequence describes a U-shape with respect to past tense formation of the verb *go*: (a) *went* → (b) *go-ed* → (c) *went*. The third sequence is taken from the development of the formation of the plural of the noun *bok* 'book' in a Swedish child (the adult target plural is *böck-er* with both change of stem vowel *o* → *ö* and the addition of an inflectional suffix-*er*). This sequence is more complex: (a) *bok* 'book' versus *bok-ar* 'book-PLUR' → (b) *bok* versus *böck-er* 'book-PLUR' → (c) *bok, böck* versus *böck-er* → (d) *bok* versus *böck-er*. The developmental sequence includes several phases of analysis. The child first erroneously generalizes -*ar*, the perhaps most productive plural suffix on nouns in Swedish, to the unmodified stem *bok*. And in the third phase, he or she reanalyzes the stem as *böck*, a form which is found in the target plural *böck-er* only (more precisely, in the third phase there is a variation between *bok* and *böck* as the unmarked form).

The fourth illustration concerns the naming of parts of a mushroom and it provides an example of U-shaped semantic development: (a) *stem, cap* → (b) *body, head* → (c) *stem, cap*. In this case the reorganization in phase (b) suggests that the child has become consciously aware of the metaphorical nature of the mushroom terms, rejecting the less transparent pair of metaphors *stem, cap* in favor of a more transparent pair of his or her own choice: *body, head*. The story of U-shaped development ends with an important moral: the child has not necessarily completed the acquisition process simply because an adult-like linguistic behavior has been attained.

For children growing up with languages with inflectional suffixes, there follows close on the heels of the vocabulary spurt a grammatical spurt involving a rapidly increasing use of the first inflectional morphemes. Investigations employing different methodologies (parental reports, longitudinal case studies, connectionistic modeling experiments) converge on the finding that the vocabulary spurt is a

precondition for (or, at least, greatly facilitates) the analysis of the internal morphological structure of words and the acquisition of inflectional morphemes. Through the vocabulary spurt the child acquires more and more words, and many of these words share the same inflectional paradigm. Through similarity abstraction (different stems, but same ending) the child can now arrive at a representation of the internal morphological structure of word forms into stems and endings. Provided that this kind of analysis has taken place, an inflectional morpheme can then be generalized in the sense that it can be applied to novel stems. Mostly, these generalizations result in correct target forms, but sometimes they result in deviant forms like *go-ed*.

For further details, see Elman et al. (1997), Bates et al. (1988).

3.2 Early Utterance Structure

Towards the end of their second year, children typically start to combine words within a single utterance, beginning mostly with two words. During this so-called two-word stage, the majority of the utterances produced by the child still consist of just one word. The words entering the child's one or two-word utterances at this early stage are typically non-inflected. They are drawn from children's budding vocabulary of mostly nouns (*daddy, ball* etc.), but also verbs (*fall, eat, etc.*), some deictic words (*that, there*), adverbs (*no, more, up*), adjectives (*wet, pretty*), and feedback words (*yeah, no*).

Crosslinguistically attested semantic roles and relations (indicated by small capitals) between the terms found in children's early two-word utterances include LOCATION of an ENTITY, ACTION, or EVENT as in *there book* or *play garden*; the relation between any two of an AGENT, PATIENT, or ACTION as in *Eve play* or *eat food*; the relation between POSSESSOR and POSSESSED as in *mama dress* ('mama's dress') or *my shoe*, the predication or attribution of a PROPERTY to an ENTITY as in *John sad* or *pretty dress*; and 'quantification' (including negation) as in *no wet, allgone milk*, or *more milk*. At the two-word stage, children typically also use one or two question words to construct questions such as *where ball?*

Children's one- or two-word utterances are situated in a larger span of connected discourse and there is often more structure between utterances than within utterances at this early stage. For example, before children can put together a two-word utterance such as *there book*, they can often produce *there* and *book* as two consecutive one-word utterances; the first, an act of reference to a given object, and the second, a predication or naming of the object just referred to. Typically, children at this stage are also in command of a couple of feedback words (like *no* and *yeah* or *mm*), words which contribute to the cohesion of the communicative interaction in that they signal contact (between the communicating parties), perception (of what the conversational partner just said or is saying) and some sort of attitudinal reaction (e.g., protest or agreement).

Further, adults typically respond to children's one- or two-word utterances (e.g., *more milk* or *where ball*) by expanding their structure, for example *do you want more milk?* or *yes, where is the ball?*, etc. These expansions serve as important models for children to expand their own utterance structures, not the least in terms of providing the required grammatical morphemes (*is, the*, etc.).

For more details, see Brown (1973), Snow and Ferguson (1977).

3.3. Terms for Spatial Relations

The cognitive development during the sensorimotor stage provides a precocious conceptual basis for the acquisition of words and morphemes encoding spatial relations. The languages of the world, however, differ not only with respect to how they encode spatial relational concepts (by lexical means, or by grammatical means such as prepositions, case endings, verb particles) but also with respect to which spatial distinctions are placed more at the center and which ones more at the periphery of the language system. In effect, the same spatial distinction (e.g., IN versus ON) can be more easily available for linguistic usage in one language than in another. The first few spatial terms that emerge in children's early language reflect this diversity of their input. Thus, children growing up with a Germanic language (e.g., English, German, or Swedish) will experience a frequent usage of the morphemes *in* versus *on* across many different situations, where the common denominator between the two spatially related objects is CONTAINMENT for *in* versus SUPPORT for *on*. And already towards the end of their second year these children tend to use *in* versus *on* in linguistic communication to classify the spatial relation between two objects. In contrast, children growing up with Korean will experience a language where the distinction between IN and ON receive much less attention in linguistic communication. Instead, the primary distinction is between TIGHT FIT and LOOSE FIT between two spatially related objects, and this is the distinction Korean children begin to render a linguistic expression towards the end of their second year of life.

The availability of the spatial morphemes to children learning language is also determined by the prosodic prominence and the input frequency of the morphemes. Many languages of the world, including the Germanic languages, frequently distribute information about spatial relations on 'satellites' to the verb, for example, *down, from, off, in*, or *up* in *fall down, from*, or *off*, or *go in, up*, or *down*. In contrast, other languages, including those of the Romance family, tend to encode this kind of information

directly into the verb, cf. Spanish *bajar* 'go down,' *subir* 'go up,' etc. As satellites, morphemes like *in*, etc. often receive stress, something which adds to their salience in the input to the child. And, typically, children growing up with satellite-framed languages often produce a small set of these spatial morphemes already at the one-word stage.

Through early language learning children thus come to upgrade certain conceptual distinctions (in that they are supported with frequently used linguistic means), and to downgrade others which are encoded more marginally.

For more details, see Slobin (1985–97), Berman and Slobin (1994), Bowerman and Levinson (1998).

3.4 Personal Pronouns

Another linguistic domain which emerges very early in children's language development are terms for reference to person.

The face-to-face setting of communication provides the domain of referents onto which children can map proper names, common nouns, and personal pronouns. The first, minimal system of contrasting personal terms to emerge in children's development is typically that between a name referring to the individual child and a name referring to the other (e.g., *mama*). When the first usages of personal pronouns emerge (first and second singular *I* and *you*), they typically take over the functions of reference to SELF and OTHER respectively, illustrating the developmental scenario that new forms often first appear in old functions. Following a developmental course of 'decentration,' children later pick up third person pronouns (*he, she, they*) as they extend their sphere of attention to talk about persons beyond the face-to-face setting and the here and now.

A developmental course of decentration can also be seen in the acquisition of nouns for reference to person. Typically, a form like *mama* is first used by children to refer to their mother in a way that resembles a proper name rather than a common noun (*mama* only applies to a child's own mother). Later, children come to generalize the term to other mothers (so that it becomes a common noun), realizing that other children also have mothers and that mothers, in their turn, have mothers whose children they are, etc.

Some children initially fail to realize that the pronoun *you* is deictically shifted (*you* refers either to the child or the other depending on who is speaking) and for a period of time they are stuck with having mapped the form *you* directly onto themselves (the child is referring to himself or herself as *you* on a par with his or her proper name). For example, wanting to claim an object from the adult, the child might say *You!*, whereupon the adult answers *Do you want it? Here you are!* The example further illustrates that adult speech directed to the child need not always help the child get the mapping relation right. In this

particular case, the adult response only serves to reinforce the child's idea that *you* applies to the child only. In order to get the mapping relation right, children need to attend to communicative exchanges where *you* is used to refer to someone else than the particular child using the term. Or they need to experience responses to their erroneous usage of *you* which are incompatible with their own usage. For example, an older sibling, competing with a child for the possession of toys, would be more likely to respond to the child's *you* by claiming the object for himself or herself than to say *Do you want it? Here you are!* Indeed, the erroneous mapping of *you* has been found to be much more common in first-born children than in children growing up as a younger sibling. The child's construction of language is indeed deeply interwoven with social interaction.

For further details, see Bruner and Garton (1978), Bowerman and Levinson (1998), Broeder and Murre (1998).

4. Discourse Skills and Development Beyond Childhood

Around three years of age most children have acquired a basic vocabulary and a basic grammar. On a discourse level, the three-year-old has acquired basic skills for engaging in conversations, including initiating topics, making comments, giving feedback, asking and responding to questions, and making and complying with requests. Many genres or linguistic activity types, such as narrative and argumentative discourse, are, however, still to develop considerably before they can be said to have reached a more mature level. Some genres, such as a letter or a composition, are associated with the written medium and typically enter the agenda for language learning only after the preschool years.

Similarly, the function of language to reflect and construct social identity and social roles (child versus adolescent versus adult, boy versus girl, etc.) is a dimension which is largely discovered and explored beyond early childhood. For example, 'discourse markers' such as *well* and *uh* participate in effecting a social-role profile of the speaker (in the case of *well*, a more adult and formal character). Studies based on English-speaking children's role-play speech indicate that by four or five years of age there is a nascent understanding of how such forms can both reflect and manipulate the relative social status of a speaker—see further Andersen (1990).

At the two-word stage, children can already describe simple, conspicuous events, for example, by saying *block fall* to describe a falling block. In picture story tasks, a much practiced technique in investigations of narrative development, children around three to four years of age can produce rich descriptions of individual pictures or scenes. These

707

descriptions, however, tend to be largely driven by details which the child finds interesting, and there is so far little or no global discourse cohesion or narrative structure. For example, in relation to the first two pictures of a picture story a three-year-old might say: (a) *The rabbit is riding a bicycle*, (b) *The cats are playing tennis*. In contrast, children between five and seven apply top-down control processes in the story telling task to effect a strong cohesion, typically at the expense of describing details in the individual pictures, for example: *There's a rabbit on a bicycle. And then he sees two cats*. Here, the rabbit is constructed as the theme of the story through an act of introduction (*there's a rabbit*) and subsequent pronominalization (*he*). Further, the child puts the rabbit into subject position (the 'thematic subject' strategy) and marks the temporal sequencing of the component events by *and then*.

And the sentences the child produces all describe events which move the story line forward. All these linguistic strategies interact to effect a salient story line and a main theme/character, that is, who is doing things and to whom things happen. Still later in development, children typically manage to combine a clear story line with the description of details and events which are off the story line in the sense that they do not contribute to moving the story forward. An example of a narrative sequence by a child in the age range 8–10 years is: *There's a rabbit going for a ride on a bicycle. And then he sees two cats, who are playing tennis*. Here, the off-story-line character of the scene with the cats is linguistically reflected by its placement in a relative clause, whereas events moving the story forward are placed in main clauses.

The presence of the relative clause in the last example is not, per se, an indication of an advanced stage of language acquisition. Relative clauses tend to be part of the basic grammar children have acquired by three years of age. In order to assess the advanced character of the stage of acquisition illustrated in the example, it is crucial to take into consideration the discourse function of the relative clause (to encode an off-story-line scene). As children begin gradually to conquer new genres in the course

of their language acquisition career, old constructions are put to partly new uses.

See Karmiloff-Smith (1979), Deutsch (1981), Slobin (1985–97), Berman and Slobin (1994).

Ebonics and African American Vernacular English

J. Baugh

The term 'Ebonics' was first introduced in 1973 at a conference devoted to the psychological development of African American children. Professor Robert Williams is the African American psychologist who

first combined *Ebony* with *phonics*, thus coining *Ebonics*. The international orientation of Ebonics was immediately evident in his definition of Ebonics as 'the linguistic and paralinguistic features which on

a concentric continuum represent the communicative competence of the West African, Caribbean, and United States slave descendant of African origin' (Williams 1975: v).

Williams and other African American social scientists who attended the conference were seeking a term other than 'Black English' or 'Black English Vernacular' (BEV) to describe the linguistic consequences of the African slave trade, and therein lies the promise and the peril of Ebonics. Ebonics resulted from the export of African slaves during European colonization of North and South America. As a result, speakers of Ebonics made contact with different European languages upon capture. Typically Ebonics speakers are African slave descendants who reside in former slave trading colonies that now use English, Portuguese, or Spanish as their sovereign national language. Williams' original definition should therefore be viewed as an international construct.

By comparison, the first documented attestations of the term 'African American English' or 'African American Vernacular English' (AAVE) did not appear until the late 1980s (see Baugh 1991, Smitherman 1991). Moreover, AAVE was introduced in direct relationship to the linguistic legacy of slavery in the United States. The fundamental question can be simply stated: 'Is Ebonics synonymous with AAVE or not?' As might be expected, the most accurate answer is that they are not truly dichotomous. Most scholars who use the terms AAVE or BEV, do so based on Labov's (1972: xx) emphatic claim that 'to suggest that BEV is not English is absurd.' Proponents of Ebonics provide mixed accounts regarding the relationship between AAVE, BEV, and Ebonics. For example, Asanti (1979: 363) observed that 'information about Black English has proliferated, creating a misunderstanding of the scope and function of the language. Ebonics as a designation for the language, usually referred to as Black English, attempts to remove some of the ambiguity created by connecting black with English.' However, four years before Oakland had adopted their controversial Ebonics resolution, Smith rejected the equation of Ebonics with BEV. He argued that 'Ebonics is not "genetically" related to English, therefore, the term Ebonics is not a mere synonym for the more commonly used term "Black English." If anything the term is, in fact, an antonym for Black English' (Smith 1992: 41).

These diametrically opposed interpretations of Ebonics, as the synonym or antonym of 'Black English' (or AAVE) were not fully evident until December 18, 1996. It was on that day that the Oakland, California School Board passed their resolution declaring Ebonics to be the official language of 28,000 African American school children who are enrolled in Oakland's public schools

(see Baugh 2000, Rickford and Rickford 2000 Smitherman 2000).

Professional linguists were ill prepared for the glaring public and political scrutiny that pursued Ebonics after its Oakland debut. As linguists pondered their reaction to the statement that 'Ebonics is not genetically related to English,' US Secretary of Education Richard Riley did not hesitate to reject Oakland's non-English assertion. He released a formal statement indicating that bilingual education funds could not be used for speakers of 'Black English.' Secretary Riley's use of 'Black English' rather than 'Ebonics' undercut the linguistic assertion that African Americans speak a language other than English.

It is also noteworthy that former US Secretary of Education's remarks followed swiftly upon Oakland's controversial resolution in less than one week. Again, Mr. Riley's statement stands in striking contrast to Smith's declaration that 'Ebonics is the antonym of Black English' (see Smith 1992).

By remarkable coincidence, the 1997 annual meeting of the Linguistic Society of America (LSA) was held in January, shortly after Ebonics captured global headlines. The Society adopted a formal resolution that differs substantially from Smith's non-English interpretation: 'The variety known as "Ebonics," "African American Vernacular English" (AAVE), and "Vernacular Black English" and by other names is systematic and rule-governed like all natural speech varieties' (1997 LSA Resolution of the Oakland 'Ebonics' Issue).

At the same time that the LSA was seeking to lend support to Oakland's linguistic claims about African American students, politicians were penning anti-Ebonics legislation in states throughout the nation, including California, Texas, and several others (see Baugh 2000). Although many of these legislative efforts died once public attention shifted away from Ebonics, they stand as statutory witness to the hostile reception that Ebonics received from many Americans from every walk of life.

In the immediate aftermath of these events the Oakland School Board revised their resolution, bringing it in line with the LSA resolution, '... these studies have also demonstrated that African Language Systems have origins in West [sic] and Niger–Congo languages and are not merely dialects of English.' (Revised Oakland Ebonics Resolution, January, 1997).

Despite the fact that the definitions in the original and revised resolutions from Oakland are diametrically opposed, the general public—indeed the global public—has come to regard 'Ebonics' as synonymous with AAVE or BEV as exemplified in the LSA resolution.

Another noteworthy interpretation of Ebonics is that put forth by Blackshire-Belay, who draws upon

linguistic interpretations that span throughout the African Diaspora, 'I extend the term Ebonics to include all languages of African people on the continent and in the Diaspora that have created new languages based on their environmental circumstances' (Blackshire-Belay 1996: 20).

Once the Ebonics media frenzy subsided, informed scholars turned their attention to the consequences of this event, including Baugh (2000), Perry and Delpit (1997), Rickford and Rickford (2000), and Smitherman (2000). Each author provides a detailed account of Ebonics as it was influenced by events in Oakland and subsequently by governmental policies. Perry and Delpit (1997) edited the first distillation of the Ebonics episode, which included insightful contributions by scholars and educators who are familiar with the plight of African American students and the needs of their teachers. Lippi-Green (1997) refers to mainstream US English in contrast to 'Standard English.' She also considers the Ebonics controversy within the broader context of other stigmatized English dialects.

Faced with public rebuke and global ridicule for their efforts, the Oakland School Board eventually abandoned the term Ebonics in favor of pursuing educational goals that could help increase Standard English proficiency among their entire student population. This includes African American students, but it also includes students other than African Americans who lack adequate proficiency in Standard English to excel academically.

Whereas Ebonics has become highly politicized, many linguists continue to use the term AAVE or African American Language (AAL) (see Baugh 1999). Smitherman (2000) has provided a helpful alternative, introducing the concept of *US Ebonics.* Smitherman's modification allows one to maintain the original international orientation contained in William's (1975) primordial definition of Ebonics, while maintaining its focus on the United States.

Due to the political and racial circumstances that have surrounded the concept of Ebonics since its original inception, its scientific utility has been greatly compromised. This will continue to be the case until scholars come to some common empirical foundations upon which to describe the linguistic consequences of the colonial African slave trade.

Education and Language: Overview
K. Perera

Language is a tool of thought, the medium through which school subjects are taught and a subject of study in its own right. The many and intricate relationships between language and education

constitute the rapid developing discipline of educational linguistics (see Alatis 1994, Stubbs 1986).

1. Categories of Language Teaching

The following categories of language teaching can be identified:

(a) Language as a mother tongue—which may be either where the mother tongue is the official language of the country, e.g., English in England, USA, Australia, New Zealand (see *National Language/Official Language*); or where the mother tongue is an indigenous language of the country but not the language associated with political power in the nation as a whole, for example, Welsh in Wales, Maori in New Zealand, Zulu in South Africa; or where the mother tongue is the language of a recent immigrant group (sometimes called a 'community language' or a 'heritage language'), for example, Arabic in Sweden, Italian in Canada, Panjabi in Britain).

(b) Second language teaching, where the language is not the mother tongue but is one of the official languages of the country, for example, English in parts of Wales, Irish in the Republic of Ireland, French in parts of Canada, Hindi in parts of India.

(c) Modern foreign language teaching, where a language is taught that is neither an official language nor a community language, for example, French in Britain, Japanese in Australia.

(d) Classical language teaching, where a language is taught that has an ancient and extensive literature but no native speakers, for example Latin, Ancient Greek, Sanskrit.

The main focus of this article is on mother-tongue teaching.

2. Language Policy and Planning in Education

Given the range of types of language teaching, and the linguistic complexity of many societies, policy decisions have to be made about the role and status of different languages within the education system, and about the provision that is to be made for them (see *Bilingualism, Societal*). In some countries these decisions are made at government level, in some at state (or province) level and in some at local or even school level. Because of the inescapable relationships between language and power, the formulation of school language policies cannot be considered as a purely educational matter, since they reflect and, in due course, contribute to the prevailing political climate (see *School Language Policies*).

2.1. Indigenous Languages in Education

At the end of the twentieth century, there was a fairly widespread acceptance of the importance of the use of the mother tongue as a medium of instruction, at least for pupils who speak a language indigenous to the country. It is recognized that learning through their own language is a key way in which children develop a sense of their own cultural identity and share in their cultural heritage. (It is also clear that it is the only way to prevent the extinction of many of the world's threatened languages.) This represents a major change from the beginning of the twentieth century when Welsh children in Wales and Maori children in New Zealand, for example, were punished if they spoke their mother tongue on school premises, and young Indian and Inuit children in Canada were forced to go to residential schools where the use of their mother tongues was forbidden.

However, this principle is not universally accepted—for example, in Tanzania, English is the medium of instruction in almost all secondary schools even though it is not the mother tongue of either the pupils or the overwhelming majority of teachers (Rubagumya 1990). Nor is the principle completely straightforward. There are practical problems—as in India, for instance, where, according to the 1981 Census, there are 89 languages that are not included in the list of 15 major languages recognized by the Constitution and yet that are spoken by more than 10,000 people; it is hardly feasible for teaching materials to be available in all of these languages. Even speakers of one of the major languages may pay to have their children educated privately in an English-medium school in order to improve their employment prospects.

There are political problems too. Whereas the indigenous peoples of North America, Australia, and New Zealand have fought for the right to be educated in their mother tongue the imposition of mother-tongue primary education on the indigenous population in South Africa by the white minority government during the apartheid regime was seen as an act of repression, since it contributed to the exceptional difficulty black pupils faced in proceeding to secondary and higher education, which was in English and Afrikaans only (Janks and Paton 1990).

2.2 Community (or Heritage) Languages in Education

As far as immigrant groups are concerned, the provision of mother-tongue education varies widely. In Australia, for example, some states encourage the use of the main community languages (e.g., Italian, German) as a medium of instruction in the primary school; and many languages are available as curriculum subjects at both primary and secondary level: there are 17 in addition to English taught in primary schools in Victoria and South Australia (see *Heritage Languages*).

Although Canada has some immersion programs in heritage languages (e.g., Ukrainian and Hebrew),

711

on the whole, the languages are taught as subjects, either as part of the school timetable or after school hours: there are classes in roughly 60 languages in Ontario, for instance.

Sweden also provides primary education through the medium of some of its 126 community languages but there, too, it is more common for the languages to be taught as separate subjects. Children have the right to 2 hours instruction per week in their parents' language; because there are so many different languages dispersed through a relatively small population, this is often provided by peripatetic teachers (see Paulston 1994).

In sharp contrast, in the UK, where there are something like 200 community languages, of which about 20 are spoken by more than 1000 school pupils—there are no exact figures (Department of Education and Science 1990: 83)—the state makes no provision for their use as a medium of instruction and rather little for their teaching as a subject. The Swann Report (Department of Education and Science 1985), which was influential in policy-making with regard to language in education, concluded, 'we cannot support the arguments put forward for the introduction of programmes of bilingual education in maintained schools in this country...we would regard mother-tongue maintenance...as best achieved within the ethnic minority communities themselves' (cited in Alladina and Edwards 1991: 23–4). The survey of 11 speech communities conducted by the Linguistic Minorities Project (Khan 1985), and the accounts of 33 different speech communities reported in Alladina and Edwards (1991) reveal vigorous community-based language-teaching programs but rather few opportunities for the children of immigrants to learn their mother tongue in a state school, especially at primary level. At secondary level, the National Curriculum in Modern Foreign Languages (Department of Education and Science 1990) requires schools to offer teaching in one or more of the eight languages that, with the addition of English, comprise the working languages of the European Community (Danish, Dutch, French, German, Modern Greek, Italian, Portuguese, and Spanish). They may, if they choose, also offer any of the following languages: Arabic, Bengali, Cantonese, Gujarati, Modern Hebrew, Hindi, Japanese, Mandarin, Punjabi, Russian, Turkish, and Urdu. In practice, the number of pupils studying these languages is rather small, partly because there is a shortage of qualified teachers and suitable teaching materials, but also because many of the non-European languages are perceived as having lower status within the British education system.

In the USA, while in some states there is a limited amount of teaching in Spanish, there is an increasing trend towards assimilationist policies, with large bilingual education budgets being spent on English

language teaching for pupils who start school speaking a community language (Fishman 1989; see also *Bilingual Education*).

2.3 Standard and Nonstandard Language in Education

Where English is an official language and the main medium of instruction, there is generally a strong expectation, either implicit or explicit, that the standard form of the language will be used (see *Standard English and Education Policy*). The UK English National Curriculum (Department for Education 1995: 2), for example, states:

> In order to be able to participate confidently in public, cultural and working life, pupils need to be able to speak, write and read standard English fluently and accurately.

Although it is clear that pupils need to have access to the standard form if they are not to be at a disadvantage in the formal settings of adult life, such as job interviews and appearances in a court of law, it is nevertheless the case that those who arrive at school speaking a variety of English that is markedly different from the standard may experience considerable difficulty both in becoming bidialectal and in acquiring literacy (see *Educational Failure*).

Within education (though not necessarily in society at large) there is widespread support for the view that pupils should not be expected to relinquish their non-standard dialect but should be encouraged to expand their linguistic repertoire by the addition of the standard variety. For example, the Cox Report, which formed the original basis for the UK National Curriculum in English, said this:

> To be effective in their teaching of Standard English, schools should teach it in ways which do not denigrate the non-standard dialects spoken by many pupils. It should not be introduced at too early a stage; teaching pupils a new dialect may be confusing when they are learning many other aspects of language use. The profound implications for pupils' relationships with their families and communities should be recognized. ... This is consistent with a general policy of widening the linguistic repertoire of pupils.
>
> (Cox 1991: 30–1)

Such a policy is easier to formulate than to implement (see *School Language Policies*). Closely associated with bidialectalism is the need for pupils to develop an understanding of the concept of linguistic appropriateness in relation to situation, audience, topic, and language mode.

The nature of the relationship between standard and non-standard varieties becomes particularly contentious where Afro–Caribbean varieties are concerned. Here the situation is made complex by the existence of a continuum from acrolectal varieties, which may be very similar to Standard

English, to basilectal varieties which differ from the standard form so substantially in their phonology, lexis, and grammar that they are completely unintelligible to English speakers who do not belong to those speech communities; further, there are creoles spoken in the USA and the UK which are based on French rather than English (Dalphinis 1991, Nwenmely 1991). Where white teachers believe that their black pupils are speaking a nonstandard—or even an impoverished or corrupt—form of English, but the pupils, and their families, see their language as an integral part of their culture and community, it is clear that there is the potential for misunderstanding, alienation, and even conflict (see *Ebonics and African American Vernacular English*).

3. Language and Learning

As language is the medium through which children learn all their academic subjects, the nature of language in the classroom is an important aspect of educational linguistic research. Focusing on spoken language, sociolinguists, ethnographers of communication, and discourse analysts have all sought to identify and describe typical patterns of interaction between teachers and pupils, and among pupils themselves. They have studied how the right to speak is allocated; how questions are asked and answered; how language is used to establish and maintain control; how the specialist terminology of subject disciplines is transmitted, and so on (e.g., Edwards and Westgate 1987, Heath 1983, Sinclair and Coulthard 1975; see also *Observing and Analyzing Classroom Talk*).

Since the 1960s, researchers have looked for possible linguistic differences that relate to social class differences and that might affect children's ability to profit from their schooling. At first these studies concentrated on features of language form, such as pronunciation, vocabulary selection, and—particularly—grammar (e.g., Hawkins 1977). In the 1980s, there was a greater focus on typical conversational styles, and on the range of functions that language serves, such as establishing relationships, describing, and recalling—with special emphasis on those that are thought to be crucial for academic success, such as predicting, imagining, and hypothesizing (see *Educational Failure*).

The 1990s have seen a growing interest in relationships between language and gender and language and ethnicity in the classroom, as evidence accumulates that certain styles of speech and conversational interaction may be disadvantageous as far as educational assessment is concerned.

In addition to the social, 'managerial,' and pedagogic aspects of classroom talk, there are the cognitive aspects. If pupils are given purposeful tasks in structured and supportive settings, they can use talk cooperatively to make what they have learnt their own; to work out solutions to problems; and to formulate and test hypotheses (see *Oracy*).

4. Literacy Learning

Probably the single most important role of the school is to teach children to read and write. Literacy is not just a useful tool for life in the adult world—important though that is. It is the means by which we gain access to the accumulated knowledge of previous generations; the key to both the enjoyment and the creation of literature; and a necessary adjunct to the critical analysis of culture and society (see *Literacy*).

Before they can become literate, children need to have acquired in speech (or in sign language) the words and grammatical structures that they will meet in their reading (see *Home Language and School Language*). Further, they need some awareness of the nature and purposes of print; for example, that it is the black marks on the printed page rather than the pictures that convey the story. Perhaps less obviously, at an early stage in their development as readers—and even more as writers and spellers—they need to have sufficient phonological awareness to be able to identify the individual phonemes in the speech stream, if they are acquiring literacy in English or any other language with an alphabetic writing system.

Whether children learn to read through an approach that has a strong phonic orientation, or through one that emphasizes whole word recognition, or through an informed and principled blend of these strategies (Adams 1990), they will learn most effectively if they read meaningful, coherent texts written in language that is familiar from stories they have heard read aloud. Once they have become skillful readers they can progress to books in which the differences between the structures of speech and writing are more apparent. In this way, their linguistic repertoire is extended, with literacy itself serving as an agent in the continuing process of language development.

From the late 1970s, a small but influential number of people have propounded the view that learning to read is as natural and as easy as learning to speak (e.g., Smith 1978). This position is undermined, however, both by the extensive differences between speech and writing systems with regard to their place and role in the history of the human race as a whole, and by the exceptional difficulty in learning to read that is evidenced by a significant minority of the population. Where such difficulty affects children with normal perceptual abilities, at least average intelligence, and an absence of emotional problems, the term 'dyslexia' is sometimes used, although it is a contentious label.

For many children, a particular source of reading difficulty is the language of their subject textbooks. A

713

number of methods are used to assess the overall level of difficulty of reading material, including cloze procedure and various readability formulae, but the study of the complex interactions between a reader's psycholinguistic processes and particular semantic, syntactic, and discoursal structures in written language is still in its infancy. If children are to succeed in the education system, they need not only to be able to understand the language of academic disciplines but also to produce it. For this reason a vigorous area of educational linguistic research in the 1990s is the description and classification of genres of writing (see *Register*; *Genre*).

5. Learning About Language

Although education necessarily entails the use of language, the extent to which different education systems expect their pupils to acquire explicit knowledge about the nature and structure of the mother tongue varies widely. In Scotland and the USA, for example, language study is an accepted part of the English curriculum, whereas in England and Wales there has been a marked reluctance since the 1960s to engage in any systematic, objective study of language (see *English Grammar in British Schools*). The National Curriculum in English (Department for Education 1995); makes a modest amount of such study obligatory under the heading 'Standard English and Language Study,' as does the National Literacy Strategy (Department for Education and Employment 1998), under the heading 'Grammatical Awareness.' It is important that language is studied not in the expectation that this will enhance linguistic skill, since the evidence available does not support this, but primarily because, as the foundation of human society and civilization, it is interesting and worthy of study in its own right.

Educational Failure
J. R. Edwards

It is a commonplace in education that some pupils fare more poorly than others. Why should this be?

Why do some children seem to be at a disadvantage from first-school entry and why should they continue

714

to achieve less than others, in some cases falling further and further behind and dropping out of school at the earliest opportunity? There are, of course, any number of reasons for individual under-achievement, but group disadvantage is, perhaps, a different matter. Certain varieties of class, race, and ethnicity which differ from majority or mainstream society (of which the school is generally representative) seem, unfortunately, to be associated with a broad area of failure. In other words, group disadvantage seems to reside, most basically, in social difference. The important issues here relate to the nature of that difference and its ramifications, and it is no overstatement to suggest that the school, as a point of contact between groups, is an arena of the greatest social and academic importance.

While educational disadvantage should not simply be equated with material poverty, there is clearly a connection and, some quarters, 'disadvantage' has often been a euphemism characterizing the poor. In 1970, Rainwater outlined the most important historical and contemporary perspectives on poverty, all of which continue in various guises. A 'moralizing' view depicts the poor as strong but lacking in virtue, somehow deserving of their deprived state and requiring control.

However, where the poor are seen as weak, a 'medical' assessment may be made—what was once sin is now sickness and social remediation is at least theoretically possible. Poverty viewed as a combination of virtue and weakness forms the basis of a 'normalizing' theory; the poor are morally similar to others, but lack the resources to cope effectively. Suggested solutions to poverty would then involve providing opportunities for self-betterment. Another perspective, reminiscent of Jean-Jacques Rousseau's 'noble savage,' holds that the poor are both strong and virtuous. In this 'apotheosizing' picture, the poor are the basic, uncorrupted, and 'natural' inheritors of the earth. Rainwater (1970) also supplies a different view, one which goes beyond descriptive value judgment and aims to explain poverty in objective ways: this 'naturalizing' view stresses either some version of biological determinism or cultural differences which set the poor apart and explain their lifestyle and values. Unsurprisingly, it is within this last perspective that most social scientific attempts to come to grips with poverty and disadvantage are found.

1. The Nature of Group Difference

Biological determinism has historically been the most pervasive of 'scientific' accounts for group disadvantage, and the 'benign totalitarianism' (to cite Rainwater 1970) often associated with it has had racist and eugenic aims (although it may be anachronistic simply to style Victorian scientists like Galton as racist in the modern sense of the term).

Strong connections were established between the widespread view that some groups were inherently less capable than others and the intelligence-testing movement begun in the last century by Binet, Terman, and others. Assessment of ability in ways that are now seen as clearly ethnocentric and biased in favor of social mainstreams had unfortunate implications in eugenic practice and theory, in the passage of sterilization laws, and in immigration control—the last two being particularly important in America. It surely comes as no surprise to learn that assessment procedures found mental deficiency especially prevalent among the Black population, nor that many Italian, Polish, and Jewish immigrants were classified as feeble-minded compared with their British and northern European counterparts.

The ultimate excesses of the biological view were, of course, evident during World War II. The argument for innate genetic deficiency then languished until Arthur Jensen, beginning in 1969, proposed that American Blacks were indeed below the intelligence levels of normal Whites. While there was a simple and predictable charge of racism leveled against Jensen, his articles did prompt close analysis within the scientific community. Of greatest significance was the relationship between measured IQ and intelligence. Some tests are clearly biased towards particular groups. An instrument designed to measure knowledge associated with culture A would clearly be inappropriate for culture B, where intelligent behavior might take very different forms; nevertheless, tests have been used in this inappropriate way, with predictable results. Aware of this, Jensen restricted himself to so-called culture '-fair' or '-free' tests, supposedly tapping more general ability. However, all tests, however abstract or nonverbal their form, are devised by someone at some time to measure something. A culture-free assessment is impossible. Some cultures are much more 'test-wise' than others and this factor, along with elements of the context within which a test is administered, clearly influences outcomes. There is a practical point to be made here. Jensen found, on average, a 10–15 IQ point difference between Black and White samples, and psychologists and educators have been virtually unanimous in saying that this is insufficient to warrant altered educational provision (Jensen himself had recommended different curricula for children with 'Level I' and 'Level II' ability).

Nonetheless, intelligence testing and its presumed implications for pronouncements about group heritability continued to surface. The studies of identical twins, which began in the nineteenth century (and which are virtually all flawed), were of great interest to Jensen. The now discredited work of Burt was apparently formative and continues to figure in discussions by Eysenck, Kamin, and others (see Edwards 1989). The net result is that while

inheritance clearly is a factor in human life, the heritability of intelligence has not been shown to be significant for crossgroup comparison nor can it be so shown until that utopian day when differences attributable to environment and social prejudice have diminished. However, while wishing to discredit the genetic deficiency argument, one has to warn that it is not a dead letter, either in the popular imagination or in academic circles. A Canadian in the Jensen mold emerged in the 1980s, for example, in the person of Rushton, a psychologist who claimed Blacks to be inferior to Whites who, in turn, were inferior to Orientals.

Environmental deficiency has also been seen as the cause of group disadvantage. Children are seen to do poorly at school because early physical, social, and psychological backgrounds are inadequate and stunting. The patterns of socialization found among some groups are believed to result in substantive deficit, hindering both inschool and afterschool success. Thus, low socioeconomic status, large family size, absence of books in the home, disdain for the life of the mind, and, particularly, poor communication between parents and children are all seen to contribute to disadvantage. The products of such homes are themselves said to be characterized by poor language skills, poorly developed 'conscience' and academic motivation, and inability to see intellectually beyond the here-and-now and the concrete.

There are, again, real difficulties with this position. For example, the contexts which generated these observed 'deficits' are suspect and, in any event, the latter are usually discussed in facile and overly general ways. Not enough is known about the links between early environment and these supposedly disadvantageous characteristics, nor about those between characteristics and schools success or failure. How could the environmental-deficiency argument account, for example, for those many pupils who succeed despite having such 'bad' backgrounds?

The chief difficulty with the environmental position is that it is suffused with a middle-class bias. Many of the 'deficits,' for example, associated with disadvantaged children could be seen as strengths in the light of a sensitive awareness of their social situation; a poor 'conscience' might be a sensible adaptation to dangerous and unpredictable surroundings; similarly, an 'inability' to postpone rewards—as demonstrated in experiments in which lower-class children were much more likely than middle-class ones to take one bag of sweets now rather than accept the offer of three bags in a week's time—makes good sense if previous experience suggests that promises are not always fulfilled. No one would deny that backgrounds and lifestyles differ; what is at issue here is whether or not it makes sense to translate difference into deficit.

If the environmental-deficit argument is weak, then it follows that educational innovation based upon it is flawed. This will include many varieties of compensatory education, head-start programs and other well-meaning interventions (including proposals completely to 'resocialize' children whose families are deemed inadequate). However, both inside and outside education, environmental deficiency continues to be seen as a strong argument to explain disadvantage. Recent studies have shown that teachers—to cite one obviously important group—are still very prone to accept it (again, see Edwards 1989 for a comprehensive review here).

If disadvantaged groups' difficulties do not spring from innate inferiorities or intellectually stunting environments, to what can be ascribed their very real educational problems? Logic and the process of elimination lead to the position that disadvantage resides in group differences, rather than in basic cognitive deficiency. Because of social comparison, and because it is clear which groups are relatively powerful and which subordinate, differences essentially become deficits. These are real enough but it is important to realize that they are essentially social deficiencies. while the problems of the disadvantaged remain, their solution can now be seen to lie in the eradication of prejudice and ill-judged assessment. In some ways, this makes disadvantage even more disabling, since history suggests that problems whose existence rests upon social norms and values are among the most intractable. Even wide-ranging social revolutions and redistributions of power are unlikely to eliminate disadvantage. In the aftermath of such movements new players may adopt new roles and the characteristics of disadvantage may alter, but the phenomenon itself seems endemic in stratified societies. This is not to say, however, that nothing can be done.

2. The Language Dimension

Language has a central and obvious position in social interaction and comparison. It is to be expected that 'different' language more accurately characterizes the disadvantaged than does 'deficient' language, and examining the linguistic dimension will flesh out the preceding generalities.

Sociologists and educators who studied class dialects in the early part of the twentieth century generally held that lower-class speakers were both insufficiently exact and grammatically deficient, their speech being less complex in terms, for example, of phrase and clause usage. It is necessary to point out, however, that usage levels, or performance, need not relate to underlying competence (habitual performance is, of course, of some interest in its own right).

The work of the British sociologist, Bernstein (1959, 1960, 1971–75; see *Bernstein, Basil*) is significant in lower-class language analysis. In the 1950s

he introduced the terms 'public' and 'formal' language. The former, emphasizing 'emotion' rather than 'logic,' is the lower-class variant, while the latter, rich in sentence complexity, is that of the middle class (which also, however, has access to 'public' forms). Public language is, above all, characterized by concrete and nonsymbolic expression in which syntactic and lexical usage is restricted. Formal language, by contrast, has great symbolic and abstract expressivity. In later writings Bernstein (1971–75) referred to these varieties as 'restricted' and 'elaborated' codes (see *Codes, Sociolinguistic*).

While some of Bernstein's statements about the codes have a decidedly 'deficit' ring to them (e.g., 'the normal linguistic environment of the working class is one of relative deprivation'; Bernstein 1960: 276), he noted some strengths associated with public language ('simplicity and directness of expression, emotionally virile [sic], pithy and powerful'; Bernstein 1959: 322). In the 1970s, Bernstein attempted to distance himself from any 'deficit' interpretation and any group comparison at the level of competence, and he specifically rejected the prevailing sentiments behind compensatory education programs for the disadvantaged. Indeed, despite some of his own rather ambiguous statements, Bernstein should probably be placed within the 'difference' camp. This does not alter the fact, however, that, whether correctly or wrongly interpreted, his work fueled the environmental deficit argument on the linguistic contribution to educational underachievement.

The results of Bernstein's experimental studies certainly showed differences of habitual usage between groups (e.g., groups of working-class messenger boys compared with senior public-school pupils). The question, of course, is what to make of them. Many deficit theorists have had no difficulty here. The intrafamily communication work done by Bernstein and his colleagues in the UK, work which reinforced the view that public language restrictions develop from inadequate mother–child patterns, was taken up in the USA. Lower-class interactions were said to of an 'imperative–normative' kind, with direct and concrete language being used to maintain parental authority and control. Communication between middle-class mothers and children, however, was considered to be of a more rational and explanatory nature, setting the stage for such useful cognitive operations as generalization, logic, and planning. Indeed, in an elegant but vacuous phrase, one American research team noted that 'the meaning of deprivation [is] deprivation of meaning' (Hess and Shipman 1968: 103). All of this work is suspect: the effects of being interviewed and providing language data generally may themselves differentiate social groups; it is difficult to generalize from such data to real home interactions; untested assumptions are made about links between variations in maternal

behavior and children's developing cognitive abilities; and so on. Also, there is again in this work a strong sense of the correctness of middle-class standards and practices.

Verbal 'deprivation' was also, unsurprisingly, a powerful element in those programs of compensation underpinned by social deficit theory. One of the most notable here began from the assumption that the lower-class (Black) child was generally retarded. Specifically, his or her language was 'immature' and 'rudimentary,' and, because of this, language was seen as 'dispensable': thus, 'language for the disadvantaged child...is not of vital importance' (Bereiter and Engelmann 1966: 42). On this preposterous basis the authors—who had apparently never observed children from the orally-rich Black culture at play—outlined a program to compensate youngsters for things they were not lacking in the first place.

None of these debatable observations about language was made by linguists, of whom virtually all have rejected the deficit philosophy from which they emerged. The famous anthropological linguist, Sapir, said many years ago that, 'when it comes to linguistic form, Plato walks with the Macedonian swineherd, Confucius with the head-hunting savage of Assam' (Guy 1988: 64) and, although we might not put things quite like that today, Sapir's thesis has proved convincing. Other linguists have rejected the idea of 'primitive' languages and, while languages are not necessarily equivalent in all forms of expression, and while some may be more useful in some contexts, such terms as 'better' or 'worse,' 'superior' or 'inferior,' are not applicable. More specifically, the same can be said for dialects and varieties within a language. All forms are adequate for the needs of speakers within their own speech communities; issues of 'correctness' need to be considered with reference to each variety's own grammar; and problems generally arise only when different varieties come into contact.

In the 1960s and 1970s this matter was thoroughly dealt with by Labov (1973) (see *Labov, William*) and his associates. He was an American linguist who chose as his test case Black English (BE)—a very good test case, since BE was widely perceived as a deficient and 'illogical' approximation to 'proper' English (see *Ebonics and African American Vernacular English*). The work had four important strands.

First, it was shown that the contexts in which 'verbal deprivation' was diagnosed were generally threatening and hence inappropriate. A small Black child questioned by a large White adult typically produced what Labov called 'defensive, monosyllabic' behavior (Labov 1973: 27). By simply relaxing somewhat the formalities associated with speech elicitation, the child's performance increased dramatically, coming more to resemble that linguistic

717

richness reflected and valued in the Black speech community.

Second, it proved possible to demonstrate that the 'restricted' speech of the lower class might well, if linguistic prejudices could be set aside, be viewed as more forceful and direct, and less redundant and verbose, than the 'elaborated' forms of the middle class.

Concrete and highly-charged language usage (showing, indeed, that 'pithy' noted by Bernstein) contrasts favorably with a more educated verbosity which hedges basic ideas with a welter of qualification and hesitation. It can be argued that qualification and caution have a place, particularly in contexts in which difficult or abstract issues are under discussion; consequently, this second strand may be the weakest or the least completely developed. Nonetheless, it usefully challenges the received wisdom about the appropriateness of middle-class usage.

The third point of importance touched upon the competence—performance distinction. Black children were found to repeat 'standard' English sentences in Black form. Given that the latter is a valid and rule-governed dialect (see below), and given that these repetitions exactly captured the original meaning, Labov (1973) argued that there was no evidence here at all for any inadequacy in pronunciation, grammar, or, indeed, basic cognitive ability. Children comprehend the meaning of what they hear, then (unsurprisingly) reproduce it in the form most familiar to them. The point was further reinforced by studies showing that White children repeating sentences phrased in BE typically employed standard forms.

The final, and most important, element in the overall argument dealt with specific aspects of BE grammar. The central and necessary point to be established here was that BE forms, though different (if not vastly different, incidentally) from standard ones, were adhered to as regularly as those of other varieties. Just two examples suffice here. One of the obvious features of BE is the deletion of the copula verb (in phrases like *He goin' to the store* or *We on tape*—where standard usage would produce *He is going to the store* and *We are on tape*). The copula verb *does* appear, however, in the past tense (*I was small then*). The regularity here is that in contexts where standard English permits contraction (*He is going* can become *He's going*), BE allows deletion (notice, by the way, that there is no loss in meaning, no ambiguity, in either case). Where standard usage prohibits contraction (for example, *He's as nice as he says he is* cannot become **He's as nice as he says he's*), so BE rules ban deletion. A final point here: the copula deletion traditionally condemned as inaccurate usage does, in fact, exist in approved form in (informal) standard English too: *That your car?*, a

strolling policeman might say to an illegally parked motorist.

A second example concerns such constructions as *She be standin' around* or *He be always fooling about*—again, typically seen by White teachers and others as incorrect. Here, the *be* indicates habitual behavior and, were it absent, the BE speaker would be referring to a present action only.

These and other demonstrations convincingly make the case that BE (and, by extension, other English dialects) is a system within which grammatical rules are obeyed, not a haphazard assortment of utterances, Indeed, given what is known of human cognitive development, the 'rule-governed' hypothesis intrinsically makes much more sense than the 'haphazard' one, regardless of specific empirical observation (i.e., what group, wherever and however it lived, could maintain itself adequately with a basically flawed communication system?). Even so, a deficit conception of language continues in many quarters, and popular prejudices still exist towards disadvantaged forms, which are often seen as indicators of innate or acquired intellectual handicap. More worrying is that allegiance to a deficit philosophy is still evident in some academic circles.

One line of argument in such circles is that, while interventions based upon language-deficit models have been of only limited success, the models themselves are not without value. Another related point is that deficit and difference theorists attended to different aspects of language, with the former being mainly concerned with semantics, the latter with grammar. In either case, the linguistically overwhelming evidence against a deficit philosophy is downplayed.

Honey (1983), a British professor of education, succeeded in muddying the waters with a monograph in which linguistic arguments supporting a different viewpoint are rejected. Honey disagrees with the central thesis that all varieties are valid systems, claiming that this undermines attempts to reintroduce 'standards' at school and pushes disadvantaged speakers into a 'language trap.' What these persons really need, according to Honey, is assistance with standard English but he complains that the contemporary linguistic stance, with its respect for all varieties, undercuts this and, in some cases, encourages the school to promote nonstandard forms. Detailed review of Honey's work is impossible here (though it has been undertaken by several prominent linguists, some of who were attacked by name in the monograph), but the main points are easily summarized. First, the author has fallen prey to a confusion between concepts and the words to describe them: thus, so-called 'primitive' groups may lack words or terms current in more 'advanced' societies, but this tells us about their physical and psychological lifestyle, not about the validity of their language

(the question of why different groups develop in different ways is, of course, an interesting one, but it need have no relationship to matters of linguistic relativity). Second, in important ways Honey misinterprets the sort of evidence adduced by Labov (1973) which bears upon the linguistic validity of BE. Third, there is a failure to understand that language differences become deficits through the medium of popular convention and prejudice. Finally, Honey mistakenly imagines that a school policy which tolerates and does not stigmatize the use of nonstandard varieties must necessarily lead to an active fostering of these varieties (and a concomitant de-emphasis on standard forms) (see *Standard English and Education Policy*; *School Language Policies*).

Notwithstanding linguistic and other insights into the nature of language variation, it is important to remain vigilant and not imagine that older and less informed views will simply vanish. For a long time social psychology has shown that the more mental energy has been invested in a particular set of perceptions, the more unwilling people are to change them, even when faced with apparently unanswerable contradictions, preferring instead to engage in various forms of denial, distortion, and self-deception.

3. Language Attitudes

It is important to understand the evidence supporting a difference interpretation of language variety. However, it may change little in a practical sense; it would be naive indeed to imagine that widespread diffusion of linguistic findings (assuming that were possible) would speedily eradicate incorrect perceptions. It is therefore necessary to consider in further detail those attitudes which translate language difference into language deficiency.

These are matters with a long history; whether it is language, dialect, or accent that is discussed, preferences and prejudices tend to come to the fore. The sixteenth-century poet, Carew, felt that the Italian language was 'pleasant, but without sinews,' French 'delicate,' Spanish 'majestical but fulsome,' and Dutch 'manlike, but withal very harsh.'

Dialect attitudes are most pertinent here, of course. While social comparison and unequal power is stratified societies lead to one dialect becoming standard (see *Standardization*), others are not substandard either linguistically or cognitively (although, if it can maintain nonpejorative status, 'nonstandard' seems acceptable for these)—a matter of *primus inter pares*, perhaps. However, works of reference have often unfortunately reinforced a 'substandard' interpretation. The *Oxford English Dictionary* (OED), for instance, has referred to dialect as a 'subordinate' form arising from 'local peculiarities'—a definition implicitly held by those for whom 'dialect' means some rustic or regional variety. Similarly, on accent, the OED notes 'peculiar' alterations of pitch,

'mispronunciation,' 'misplacing of stress,' and 'misinflection.' Little wonder, then, that it is still easy to find people who claim they have neither a dialect nor an accent, or to discover others eager to shed unwanted and socially stigmatized forms.

If dialects cannot distinguished linguistically as 'better' or worse,' could it be that some are aesthetically more pleasing than others? This has certainly been a feature of much popular prejudice and in his 1934 monograph, *The Best English*, Wyld claimed that any unbiased listener would find RP ('received pronunciation') the most pleasant, the most educated, and the variety best suited for formal purposes. He touched upon the heart of the matter with the word 'unbiased'—how does one obtain such a listener? Work by Giles and his colleagues attempted to illuminate this. They began by noting two basic possibilities: either some forms *were* intrinsically more pleasing than others (the 'inherent value' hypothesis), or aesthetic judgments proceeded from assessments of the social standing of the speakers. To test this, judges, unfamiliar with language varieties were asked to evaluate them on aesthetic grounds. In one study, Welsh adults with no knowledge of French were unable to differentiate European French, educated Canadian French, and working-class Canadian French on this basis (even though different levels of pleasantness were found by judges drawn within the French speech community). In a second experiment, English speakers knowing no Greek were asked to rate Athenian and Cretan varieties which, in the Greek context itself, are clearly marked as high and low status, respectively. Again, no inherent aesthetic superiority was detected. This leaves what Giles termed an 'imposed norm' explanation, one which rests upon the power of social convention and belief. The comic effect of having a stage duchess with Cockney speech reflects ingrained and widely shared speech-community standards.

A further demonstration of the purely arbitrary nature of status judgments is provided by Trudgill. In England, speakers of the high-status RP do not pronounce the postvocalic *r* (in words like *cart* and *mar*), while in new York exactly the reverse holds—the higher a speaker's social standing, the more likely he or she is to sound the *r*.

More fine-grained analysis of language attitudes followed upon the introduction of the 'matched-guise' technique by the Canadian psychologist, Lambert (see *Lambert, Wallace E.*). Here, judges evaluate recorded speakers' personality traits after hearing them read the same passage in each of two or more 'guises.' Any rating differences can then be ascribed to language factors, since paralinguistic variables (pitch, tone of voice, etc.) are of course constant across samples. Two points are important here: first judges must not realize they are rating the same person using different dialects or accents (and

typically they do not); second, the reasonable assumption is made that attitudes towards speech are, in fact, attitudes towards speakers—the speech acts as a trigger for a social stereotype, from which flow specific judgments, preferences, and prejudices.

Widespread use of this method in many different contexts revealed that dialect evaluation generally involved three personality dimensions. Some dimensions of evaluation (including traits like 'intelligence' and 'industriousness') reflect a speaker's perceived competence; some ('helpfulness,' 'trustworthiness') reflect personal integrity; and some ('friendliness,' 'sense of humor') underlie social attractiveness. While, as might be expected, high-status dialects generally evoke high ratings of speaker competence, they do not elicit strong perceptions of integrity and attractiveness: on the contrary, these last two (sometimes collectively seen as representing a larger, group solidarity, dimension) are more associated with lower-class and lower-status varieties. Experimental results are, in fact, more involved than this summary suggests, but a reasonably fair gloss might note that higher-status speech forms are popularly associated (by both middle-class and lower-class judges, incidentally) with speaker intelligence, ambition, and drive, while the dialects of disadvantage connote trust, linking, and a general down-to-earth quality. The findings are not, then, entirely negative for the disadvantaged population by any means, but the great importance of personal competence (or the perception of it by others) remains central in educational and other settings.

Teachers' attitudes are of particular significance here since there is no reason to assume that they will diverge greatly from those of society at large, and because their perceptions may be especially salient in the definition and maintenance of disadvantage. There is a large literature on teacher expectations and the effects they have upon pupils' self-regard and scholastic progress; specifically, it has been shown that the formation of expectations rests upon existing knowledge (and ignorance) and early assessment of children's characteristics. A child whose speech is perceived as substandard, and whose cognitive capabilities are questioned in turn, will be categorized and stereotyped in specific ways. There is, of course, nothing inherently wrong or unnatural with teachers' expectations; they proceed from a universal tendency to simplify and understand a complex world which, without classification, threatens to overwhelm. But the familiar dangers of stereotyping and prejudice involve inaccurate, irrational, or incomplete categorization, often with harmful effects. Educational misperceptions based upon incorrect language assessment may create difficulties where none need exist. There is, perhaps, a special element of tragedy here inasmuch as the disadvantaged children likely to be inadequately understood in this way exactly those

children whose lives are already burdened with more tangible and inescapable weights. Experience suggests that the phenomenon of the 'nonverbal' child (to give but one example) may often be one created by teachers insensitive to crosscultural (or cross-subcultural) differences in the domains of competition, response to authority figures, customary reaction to threat, and so on.

It is perhaps unnecessary to state that teachers are not simply and generally being accused of malice, racism, or 'classism' (although these qualities exist among them, as in the general population). Teachers are more concerned than most with the promotion of tolerance and increased social mobility. However, once installed in the classroom, there is evidence that teachers are quickly socialized into the traditional ways of the school. In this way disadvantage is perpetuated. Studies in the 1980s in North America and Europe have confirmed this, and also confirmed that contemporary teachers, more tolerant of language variation than previously, still adhere in the main to a deficit view and still consider one of their major tasks to be the elimination of 'incorrect' speech patterns and the inculcation of 'proper' ones.

For example, in a study of primary and secondary teachers in Nova Scotia, Edwards and McKinnon (1987) found that disadvantage-as-deficit maintained its appeal; while teachers stressed the importance of home background characteristics as contributors to disadvantage, they clearly viewed some environments as substantively deficient. With specific regard to language, teachers believed that disadvantaged children were incapable of properly articulating their thoughts, and generally placed little value no receptive and expressive skills (see Bereiter and Engelmann 1996, Hess and Shipman 1968). Minority-group children (in this study, Blacks and Acadians) were particularly singled out, with Black pupils seen to have a 'slang language all their own.' A European review by Hagen (1987) indicates that some countries, like France, retain a centralist view of standard language, while others (The Netherlands, for example) have more liberal legislative perspectives on dialect variation—even if not always matched by school practice. Citing Dutch and Italian work, Hagen notes that non-standard-speaking children's favorable attitudes to their own speech often decline dramatically as they grow up.

4. Educational Responses to Disadvantage
Language varieties associated with relatively subordinate groups are not inherently deficient, but they do possess negative connotations because of social stratification and comparisons which lead to denigration. Thus, social differences become deficits and nonstandard speech becomes substandard. While still waiting for an end to the unfair and inaccurate language perceptions which contribute to educational

disadvantage and failure, it is not unreasonable to consider what schools might be doing.

First, of course, schools and teachers must become more aware of the relevant psychological and linguistic evidence bearing upon disadvantage. The wider society is generally ignorant of this, so there is, then, a real limitation on schools. On the one hand, schools tend to reflect mainstream society more than they lead it; on the other, even were schools to become centers of linguistic enlightenment, their students would still emerge into somewhat darker settings. Given these limitations, it is still quite possible for schools and teachers to be linguistically educated; the essentials of the difference-deficit argument, for example, are not difficult to grasp and do not require lengthy exposition or sophisticated prior knowledge.

Second, given the practicalities of living in a society, it should be assumed that a standard language variety will continue to be important and particularly valued, and that increased mobility will be positively affected by facility with it. The recommendations made by some linguists that schools should actively encourage (in writing, as well as in speaking) nonstandard usage may seem somewhat naive. Indeed, a common accepted standard can be a levelling device rather than an exclusionary one, and a great asset in personal and group communicative efficiency. It would be a cruel irony if a rather innocent regard for all varieties resulted in a social babel where, it may be assumed, certain groups would again end up at the bottom of the heap.

Does this not bring us back to the rejected position associated with Honey (in Sect. 2 above)? The difference is this: while it would be inappropriate and unjust for schools to neglect the standard (and while, incidentally, this would arouse great resentment on the part of disadvantaged groups themselves), a linguistically enlightened policy demands tolerance at school for all forms. Furthermore, the best available evidence indicates that this tolerance should accompany very clear messages that mother-tongue varieties of every kind are both valid and valuable. The aim should be language repertoire *addition*, not *replacement*: a policy of bidialectalism. Again, the evidence suggests that this is not at all an insuperable task to require of children (consider the bilingual facility), nor need it be solely a school-based imposition. When discussing disadvantage, groups existing in the same large society are being treated; in terms of language, this means that disadvantaged groups typically have a considerable, if somewhat passive, exposure to standard forms, forms which are clearly associated with desired social contexts and rewards. Findings concerning sentence repetition indicate this latent standard facility; other evidence supports the fact that disadvantaged children, from an early age, can comprehend standard forms and,

indeed, will use them themselves if they judge this appropriate. Schools, then, should activate this knowledge and make it clear to children that a broadening of their performance skills makes sense.

This is a matter of some delicacy, however, for children are being asked to accept two social facts which could easily be seen as contradictory. On the one hand, the message is that the mother-tongue variety is perfectly adequate within the home speech community, both for communicative purposes and as a vehicle of group solidarity. On the other, the child is to be made aware that a life beyond that community may require repertoire expansion. Transmission of these two messages requires tact and sensitivity based upon adequate knowledge of children's language and culture but it will be assisted in many cases by a desire for mobility which is unsurprisingly strong in most disadvantaged communities. Indeed, one might note that the low regard for education supposedly characteristic of the lower class (in the deficit perspective) is much less common than a sometimes overoptimistic hope for mobility through education.

Experience, including that derived from deficit-inspired compensatory programs, suggests that formalized and drill-like language curricula make little sense. They run the risk, above all, of instilling a 'replacement' perspective which is both uncalled-for linguistically and potentially damaging psychologically. A more *laissez-faire* policy seems appropriate, in which teachers act as standard-speaking models (in other words, naturally) and in which children's own good sense will lead to the desired expansion. Anything more formal will be counterproductive and will, at the least, contribute to an unnecessary rift between the child's school life and his or her unselfconscious participation in the community. Moreover, it should be noted again that this apparently *laissez-faire* policy is not simply some default option, but a reasoned and aware reflection of all the evidence and insight presented here.

Developments in fine-grained analysis of classroom communication hold out the hopes of refining awareness and improving practices. For example, the traditional assertions that disadvantaged children's 'restricted' usage leads to difficulties with the 'elaborated' language of school are undercut by real classroom patterns, which are very often delimited exercises in control—both particularistic and concrete. Indeed, the view of schools as middle-class institutions has itself been challenged on these grounds. In fact, this challenge cannot be sustained—schools are middle-class in the attitudes, skills, and values stressed there—but there is clearly more work to be done in ascertaining classroom dynamics (see *Spoken Language in the Classroom*; *Observing and Analyzing Classroom Talk*).

Ethnographic analysis of classroom language are now paying greater attention to such factors as the psychological context in which teacher–pupil interactions occur, a context in which postural configurations, direct and indirect verbal strategies, conversational rhythms, and prosody are important; these and other aspects clarify how impoverished traditional deficit-based and disembodied speech analysis are. Also central here is the interpretation of tacit school rules based upon teachers' needs for order. There is a more subtle treatment of the classroom as speech domain, where a whole cultural 'code' must be mastered for success. The implication is that disadvantage may be partly understood as an incomplete grasping of this code, which combines both knowledge and its 'appropriate' display (see Mehan 1984).

If traditional school practices required pupil adaptation in a sink-or-swim approach, while compensatory intervention programs were heavy-handed with insensitive alterations built upon insecure foundations, new approaches founded on subtle observation may help with both the school adaptation to classroom heterogeneity and a desired repertoire expansion on the part of children. Mehan's (1984) study demonstrated that detailed assessment of language styles between teachers and disadvantaged children allowed practical advice to be given to teachers about how best to adapt. This had the effect of lessening the passivity and 'nonverbality' of the pupils and, once greater participation was established, children were gradually and subtly introduced to 'school styles.'

To reduce educational failure associated with group disadvantage, a combination of practical innovations and the transfer of existing psychological and linguistic information is needed. Ethnographic analysis of classroom discourse promises useful insights which can quickly be turned to the benefit of the disadvantaged (and their instructors). It is equally important, however, to provide teachers and others, such as speech therapists, with a much more detailed knowledge of language variation and its ramifications. While the mechanisms of disadvantage are outside the reach of school alone, there is no reason for classroom experiences to add unnecessarily to children's problems. A failure to try to ease these burdens is, in fact, a repudiation of the essence of education in a civilized society.

5. Developments in the 1990s

Things have not changed greatly in the 1990s; the basic issues underlying educational failure, in the sense discussed here, remain. Thus, the informed, academic support for the different-but-not-deficient interpretation of scholastic and linguistic disadvantage must still contend with broader and more popular views which either perceive disadvantage as substantive deficit (in more or less direct fashion), or else effectively translate difference into deficiency (through the operation of language attitudes and stereotypes, for example). The calls made (in Sect. 4 above) for greater general awareness of the nature of disadvantage, and for more sensitive treatment of language at school, in particular, must unfortunately be reiterated. Controversies surrounding *Ebonics*—as African American vernacular English has recently been styled in some quarters—provide a good example of the continuation of those heady intertwinings of knowledge and ignorance, prejudice and innocence, which we have so often seen before.

One or two of the major players mentioned above have re-entered the fray; the general impact, however, has been more to reinforce original positions than to advance understanding. Bernstein (1997: 47) discusses the context within which his code theory was formulated and presented, and—rather disingenuously, perhaps—observes that the difference/deficit debate was 'of little theoretical significance' and 'obscured more than it revealed.' He also offers here an analysis of Labov's 1973 paper, but pays no attention to the grammatical aspects which were characterized (in Sect. 2, above) as 'the most important element in the overall argument.' An interesting defense of Bernstein and his work has also been mounted by Robinson (1998), who correctly points out that many of the views for which Bernstein was most vilified were not, in fact, his views at all. Robinson also maintains that academic criticism of Bernstein was essentially non-constructive, not 'Popperian-based,' and often personalized; while such criticism certainly arose in some quarters, it would be a mistake to imagine that more measured treatments were absent (see Edwards 1989). In a book published in 1997, Honey has re-emphasized his views (initially expressed in 1983) of standard and nonstandard language, views which have attracted considerable criticism for reasons already discussed here (see Sect. 2, above). More recently, Honey (1998) has suggested that academic criticism of his thesis is marred by false argument and innuendo.

In general, then, it is fair to say that the social conditions and the social prejudices which produce and maintain the educational failure associated with group disadvantage are still very much with us. It is also fair to say that much of the discussion of the issue—within and without the academic cloister—continues to generate more heat than light. Consequently, while the sentiments expressed in the final paragraph of the preceding section are still valid, it must be admitted that the 1990s do not suggest much ground for optimism.

English Grammar in British Schools
A. M. Philp

Everyone seems to have a view on grammar teaching. In late twentieth century Britain it was a subject of public debate which even involved the Prince of Wales. It is useful, therefore, to trace the development of this controversial topic from the early 1960s, when the established pattern of English teaching in British schools began to change. This development can be viewed in terms of a swing from one extreme to another; from (a) the Traditional Grammar Approach, which regards explicit traditional grammar teaching as central to maintaining linguistic standards, to (b) the Creative Writing Approach, which emphasizes pupils' *use* of English, particularly in imaginative writing, as central to their linguistic and personal development. This second approach rejects explicit discussion of language features in relation to pupils' use of English. However, for many teachers, there was movement to a third, intermediate view, which may be termed Language-Study-Based Approach. This is influenced by a range of academic language studies, and emphasizes talking with pupils about how specific language features create meaning in texts, spoken or written, produced by pupils or by others. It can also involve pupil investigation of aspects of how language varies, how it is acquired, how it changes, etc. Two strands of this third approach can be distinguished, differing as to whether or not teachers should adopt explicit language terminology when discussing language with their pupils.

1. The Traditional Grammar Approach

At the end of the 1950s, pupils were drilled in grammatical analysis of sentences and parsing of 'parts of speech' from upper primary until the final stages of compulsory schooling, and this grammatical prowess was tested in British public examinations at ages 16 or 17. The Bullock Report said of the GCE O-level examination papers established in the early 1920s:

> Forty years later, in the early sixties, they had changed little. There was a precis, letter writing, paraphrase, analysis and other grammatical exercises, the correction of incorrect sentences, the punctuation of depunctuated

passages, and, of course, an essay. [For an example of a typical paper, see Keith 1990.]

(Department of Education and Science 1975: 177)

Such a catalog of activities obviously goes well beyond grammatical analysis, broadly defined by Bullock as: 'an analytical study of those formal arrangements of items in a language by which utterances have meaning' (Department of Education and Science 1975: 169). Yet the emphasis on the eradication of grammatical solecism, and on the practice of punctuation, is what is often popularly meant by 'grammar' teaching.

The thinking behind traditional school grammar was essentially prescriptive, in the tradition of eighteenth-century prescriptive grammarians, such as Robert Lowth, and Lindley Murray, who attempted to 'fix' the language by prescribing exactly what constituted correct usage. The traditional school grammars held sway for at least 200 years. They were based on prescriptive attitudes, on forms and rules derived from Latin, and on exercises on the correction of sentences. There were two central assumptions: (a) that there is a correct standard form of the language normally only found in writing; (b) that pupils' development in written linguistic skill depends upon their being taught this grammar explicitly and being trained in its use (see *Prescriptive and Descriptive Grammars*).

Despite the pressure of the other approaches from 1960 to 1990, the traditional grammar alternative still survived in many schools. The Bullock Report's survey (Department of Education and Science 1975) found that 82 percent of all 9-year-olds surveyed spent at least half-an-hour per week on grammar and punctuation exercises.

Twenty years later, in a survey of 10 local education authorities carried out by the Schools Curriculum and Assessment Authority (SCAA) from 1995 to 1997, it was found that 'explicit planning was patchy and that much coverage was implicit.' Yet the survey did show that, in relation to phrase, clause, and sentence structure, about one-third of schools at Key Stage 2 (ages 8–11) and about one-quarter at Key Stage 3 (ages 11–14) included all the aspects set out for the English Order of the National Curriculum (SCAA 1995). In relation to the grammatical functions of words, about one-third of Key Stage 2 reported covering these and in Key Stage 3 less than half the schools referred to all the categories of words in their schemes of work. Although this situation was hardly satisfactory in the light of the requirements of the English Order, it does suggest that the reaction against traditional grammar which apparently held sway throughout the 1970s and 1980s in England and Wales, did not mean, by the 1990s, the wholesale disappearance of traditional grammar teaching from schools.

2. Reactions Against the Traditional Grammar Approach

In the early 1960s in Britain the dominance of traditional grammar in English mother-tongue teaching was weakened by several pressures, central among which was teachers' dissatisfaction with activities which were seen as boring for pupils and unrelated to the development of skill in writing. This stance was supported by the findings of a number of research projects which questioned the assumption that formal grammar instruction leads to a development of written language skills (e.g., Macaulay 1947). Later the work of Elley and his associates in New Zealand, on a longitudinal study involving traditional grammar, transformational grammar, and a control group, showed that 'English Grammar, whether traditional or transformational, has virtually no influence on the language growth of typical secondary school students'.

Another major factor leading to the reaction against traditional grammar in England and Wales was the growth of interest in the 'creative writing' approach, whereby the child's potential for creativity was to be fostered through a series of motivating experiences involving widespread exposure to talking, reading, and writing. 'Fluency' was to be encouraged; consequently, teachers were careful to avoid attempts to 'correct' or 'improve' the child's creation, either during or after the act of writing. This doctrine fueled the extreme reaction against the traditional approach which was outlined above, although it did survive within O-level examinations.

3. Operational and Explicit Knowledge of Language

The assumption that direct teaching of grammar as an end in itself will lead to improvement in writing is contradicted by the view stated in a bulletin of the Scottish Central Committee on English (1972), *The Teaching of English Language*:

> ... The sorts of language work described here will be facilitated by the use of suitable grammatical vocabulary, some of which will have been acquired earlier by means of 'mention' ... The vital point is that grammatical terminology should be produced only in response to *need*. The grammar to be taught should be limited only to what pupil and teacher require.
>
> Scottish Central Committee on English (1972: 22)

Grammatical concepts and terminology may be drawn upon by teachers as they discuss with pupils what meaning is being created in written texts, and how it is being created, but this is not the same as teaching grammar on the assumption that the pupil has to be taught the forms in order to be able to use them.

This latter point implies a key distinction between 'operational' (implicit) and 'explicit' knowledge of

language. As the Scottish Bulletin explains, 'the knowledge of his language which the schoolchild possesses is an operational one ... His knowledge of language allows him to use it but not to describe how he uses it.' Herein lies the confusion in popular claims that children must be 'taught the rules of grammar' if they are to 'improve' their use of English. In fact, they potentially 'know' most of the grammar already; what they have to be taught is how to utilize this knowledge appropriately. In such teaching it may be beneficial for teachers to draw upon grammatical terminology, if they consider it appropriate. This alternative view of the role of grammar became a central feature of one strand of the language-study-based approach.

4. 'Linguistic' Approaches to Grammar Teaching

By the early 1960s, the reaction within academic linguistics in the USA against the 'unscientific' and 'notional' basis of traditional grammars, coupled with the growth of Structural Linguistics, led to an upsurge of structuralist-based grammar teaching in American and Scottish schools. This 'cut-and-dried,' 'scientific' grammar had an appeal for school teachers, despite its lack of subtlety in relation to meaning. Similarly, there was Scottish interest in Hallidayan Scale and Category grammar, which supplied teachers with a new 'linguistic' grammar to replace the traditional one in classroom teaching.

In the USA, in the later 1960s Transformational Generative Grammar began to replace structural grammar as the preferred model in American schools. Nevertheless, this development in the USA did not lead to the establishment of transformational grammar in British schools at all, perhaps because of the complex demands it made upon both teachers and pupils.

It is worth noting, first, that all these developments still rested firmly on the assumption that grammatical structures should be *taught* in classrooms; and second, that these ideas, while popular in the USA and Scotland, did not become prominent in England and Wales. Throughout the 1960s, in fact, there was a considerable gulf between the broad approach of progressive teachers in England and Wales and those in the USA and Scotland. In England, 'creative writing' approaches and 'Leavisite' views of the central importance of literature as a moral and linguistic developmental force held sway, coupled with an extreme antipathy to anything remotely connected with grammar teaching.

5. Approaches Based on Language Studies

Two other approaches to language teaching which developed in the 1960s became prominent during the 1970s and 1980s. They were two strands of the language-study-based approach, with one taking an implicit, and the other an explicit, approach to discussing language with pupils. The 'implicit' approach, associated with the work of Douglas Barnes, James Britton, John Dixon, and Harold Rosen, saw the development of the child, as language user and mature human being, as being rooted in 'exploratory talk' and 'expressive writing,' as the child strove to find his individual 'voice' and in the process developed as a person. Its proponents saw literature and language study as equally important in this process but they took a stance against the explicit and systematic use of terminology from linguistics. They concentrated on developing their own eclectic approaches to how meanings are made in talk and writing. This view can be summarized as:

> Discussion of the audience's needs and whether they are being fulfilled is often valuable, but this is discussion in terms of content or style. Such discussion, though it necessarily refers to particular features in texts, need not demand that pupils first master an extensive generalised system for describing those features.
>
> Barnes (1988: 37–38)

The 'explicit' strand of the language-study-based approach had its genesis in the Programme in Linguistics and English Teaching, directed by Halliday at University College London, from 1964 to 1969. This developed an approach which drew directly upon the insights of linguistics and considered their implications for mother-tongue teaching. The *Language in Use* materials which emerged from this program set out a variety of activities which involve pupils in investigations into a wide range of aspects of language as it is used in society: the relations between spoken and written language; language in social situations; patterning in language; etc. (Doughty et al. 1971). The focus is not upon 'teaching grammar' but creating knowledge for pupils about language as they meet it in daily life, and upon their using a range of registers as they investigate these concerns.

The Bullock Report (Department of Education and Science 1975) broadly supported both these strands, although it is fair to say that its basic philosophy was closer to the Barnes–Britton alternative. Nevertheless, the Bullock Committee took a broadly similar stance to the Scottish Central Committee on English (1972) on 'explicit rules and facts about language,' saying that these have direct practical value to pupils when they solve particular problems on the tasks they are engaged on, or when pupils are able to reconstruct for themselves the analysis that led to the rule. The views of the Bullock Committee were summed up thus:

> What we are suggesting then, is that children should learn about language by experiencing it and experimenting with its use. There will be occasions when the whole class might receive specific instruction in some aspect of

language. More frequently however, the teacher will operate on the child's language competence at the point of need by individual or small group discussion. As a background to all this activity, he should have in his own mind a clear picture of how far and in what directions this competence should be extended.

(Department of Education and Science 1975: 173–74)

6. The Role of the Teacher

The question of the teacher's knowledge introduces two key, related, questions: (a) how far teachers, as opposed to pupils, can benefit from an explicit knowledge based on the insights of language study; (b) how far and in what circumstances they should make that knowledge explicit to pupils. The debate which developed in the 1970s between the *Language in Use* team and the linguist Crystal (1976) centred on the issue of how far teachers would have to be trained in linguistics in order to work with *Language in Use* successfully. Certainly, the Kingman Report, published in 1988, saw the issue of training teachers in knowledge about language as a main priority and the LINC (Language in the National Curriculum) in service training project in England and Wales was a direct response to this need. The LINC team questioned the making of a clear distinction between 'implicit' and 'explicit' approaches. The project's director, Carter summed up their position: 'It would be wrong to assume that conscious knowledge operates independently of unconscious knowledge; there is a constant interplay and interaction between different modes of knowing and explicit, analytical attention to language can and should serve to deepen intuitions' (Carter 1990: 18). Carter and his associates, in fact, believe in the coming together of the two strands of the language-study-based approach in the development of the overall language awareness of the pupil.

Certainly, it is important that the teacher should have a clear awareness of how grammatical features serve to create meaning in a text: say, how strings of premodifiers in a noun phrase can create a sense of density and impressive technicality in a car advertisement (as in 'the BMW Motronic digital engine management computer'). The teacher can then decide how far he or she wishes to draw upon such awareness explicitly in discussion with pupils, but it *is* important that the teacher can clearly see how such grammatical features serve to create relevant meaning in texts.

Hasan proposes three levels of literacy: 'recognition literacy,' 'action literacy,' and 'reflection literacy.' These are, in effect, three types of learning outcome, which can drive the approaches of teachers of language. Recognition literacy is the focus upon the recognition of language forms and the labeling of them as ends in themselves—upon isolated sound–

symbol correspondences in early reading, upon parsing of parts of speech, and analysis of clauses in traditional grammar. Hasan points out that this kind of language activity 'is a conception of language far removed from social semiotic practice, that is, from the making of meanings which serve our social purposes in life' (Hasan 1996: 388). The latter is largely what she means by 'action literacy.' Yet this is not seen as a denial of the relevance of explicit knowledge of language. As she says,

> It is important to note … that in order to achieve the goals of action literacy, pupils will need to have internalised the sorts of information that form the content of recognition literacy: they will need to be able to recognise the relations between the written shape and the spoken words, and they will need to know about the lexicogrammar. But there is a crucial difference. In action literacy, all this learning will be harnessed to some act of meaning (Hasan 1996: 401).

Hasan also questions recognition literacy on the grounds that it creates a passive, unreflecting view of literacy:

> Logically, the ideals of recognition literacy demand pupils who are not likely to ask questions, who are willing to follow wherever authority in the guise of the teacher leads them; they have to be pupils who do not expect their educational knowledge of language to have any direct relevance to what they do with language in the living of their life (Hasan 1996: 391).

This leads us to Hasan's third level of literacy, 'reflection literacy,' which advocates that we need to enable pupils to produce, rather than to reproduce knowledge, by developing in them 'the ability to reflect, to enquire, to analyse and to challenge' (Hasan 1996: 411). At first sight this seems very similar to the stance of the Bullock report, but Hasan advocates an *explicit* approach to the ways in which language operates to create meaning in texts. She explains it thus:

> To put a question to a text—to ask why the said is being said, what it implies, and on what grounds—calls for a much deeper understanding of language as a resource for meaning. So teachers will need to sensitise pupils to not simply the overall structure of the text …, they would also be concerned to show what alternative ways there are of saying the 'same thing.' The point is that one can never say exactly the same thing using a different wording, so in fact the teachers will need to make pupils aware of the sorts of difference in meaning that may arise from putting it one way as opposed to another … It is from this kind of deeper understanding of what the text means that we can move to explanation questions.

For example, in the discussion of the noun phrase from the car advertisement above, the teacher could encourage enquiry into ways in which the same

component could have been described in different ways in other contexts; the implications of this type of writing for the exploitation of potential consumers; the nature of jargon as opposed to technical language; the role of advertising in our society, etc. (see *Critical Language Awareness*).

The approach to teaching outlined here, however, assumes considerable knowledge on the part of teachers, and we must now consider the level of teachers' grammatical knowledge in Britain at the end of the twentieth century.

During the 1990s a number of surveys investigated the extent of teachers' and student teachers' knowledge of grammar in England and Wales. For instance, a detailed study of student teacher attitudes by Williamson and Hardman (1995) concluded that 'while the questionnaire only looked at grammar at the sentence level, which should constitute only one part of a wider framework of language study, it does reveal significant gaps in the student teachers' knowledge, although it is not as low as some critics might have us believe. It also reveals misconceptions and the lack of a metalanguage for talking about and analysing language use' (Williamson and Hardman 1995: 129).

The SCAA survey (1995–97), which investigated teachers' confidence in planning for and teaching aspects of grammar, showed fairly similar results. 'The teachers acknowledged the limitations of not having a technical language to explain grammar, although such terms as noun, verb, adjective, adverb, conjunction and tense were widely used' (QCA 1998: 26). The QCA paper on the survey comments that 'although teachers at both key stages felt confident teaching at whole text level, this confidence did not extend to phrase, clause and sentence structure, either related to reading or in pupils' own writing. Sentence structure was found to be the least systematically covered in planning at both key stages,' and 'the levels of confidence recorded for their knowledge of, and ability to teach, sentence structure were considerably lower than for any other aspect of the survey, except identifying modal verbs' (QCA 1998: 27). Clearly, teachers, at pre-service and in-service stages, needed considerable input in relation to both grammatical descriptions and teaching methodology. On the latter point, the QCA paper reported that 'many (schools) commented on the difficulty of finding effective strategies for teaching sentence structure and grammatical terminology in the context of pupils' reading and writing' (QCA 1998a: 34). The in-service materials for the National Literacy Strategy (DfEE 1998b, DfEE 2000) and the QCA booklet 'Not whether but how: teaching grammar in English at Key Stages 3 and 4' (QCA 1999) were specific attempts at the end of the twentieth century to provide such strategies and information.

7. Developments Since the Bullock Report

The years since the publication of the Bullock Report have seen a range of developments relating to the place of grammar in English teaching, and these can be summarized in relation to the outline in the Cox Report of the kind of grammatical description which is now considered relevant:

It should be:

(1) a form of grammar which can describe language in use;
(2) relevant to all levels from the syntax of sentences through to the organization of substantial texts;
(3) able to describe the considerable differences between spoken and written English;
(4) part of a wider 'syllabus of language study'.
  (Department of Education and Science 1989: 4.28)

The first point refers to the need for grammatical descriptions which are functional or communicative, in that they are oriented to describing how meanings are created within various contexts of language use (for a survey of such grammars see Mittins 1988; for exemplars see Department of Education and Science 1989). Such grammars are useful for the teacher insofar as they show how meaning is created within specific texts in particular registers. Perhaps the most useful is Halliday's Systemic–Functional model, which underpins much Australian work aimed at the development and assessment of children's writing within specific genres in primary schools (see Christie 1986; Martin and Rothery 1986).

The second point builds upon the development since the early 1970s of studies in discourse analysis, or how sentences are related to each other in whole texts. This approach has taken grammar beyond the confines of the sentence to provide a more informed basis for teachers helping pupils to improve both the structure of their writing and the cohesive linkage of their sentences.

The third point highlights the growing importance of spoken English, which has led to the examining of talking and listening in both GCSE English in England and Wales and Standard Grade English in Scotland. Also in Scotland, from 1999 onwards, the new national examination framework, 'Higher Still,' included assessment of speaking and listening within English at all levels throughout the upper stages of secondary (see Sect. 9). This interest in the spoken word has led to a great deal more analysis in schools of spoken English grammar and its comparison with written English, sometimes through transcripts collected by pupils or students themselves (see *Oracy*).

On the nature of spoken language and its relationship with written language, Halliday has reminded us of the richness of unselfconscious spoken language. '... it is only in the most spontaneous, un-self-monitored kinds of discourse that a speaker stretches his semantic resources to the utmost ... it is in

unconscious spoken language that we typically find the truly complex sentences' (Halliday 1988: 38). The educational implication therefore is that teachers ought to enable pupils to develop this potential richness of language use and to take part in investigating it. In another important paper, Halliday also identifies the changing nature of the relationship between spoken and written language in the modern world of word processing and instant playbacks. Yet, as he says, 'it is not ... a question of neutralising the difference between written language and spoken. What the technology is doing is creating the material conditions for interaction between the two, from which some new forms of discourse will emerge' (Halliday 1996: 356). Therefore, the enhanced position of spoken language in schools must take full account of these factors.

The fourth point focuses attention on various initiatives aimed at developing investigative language studies of various kinds, under the aegis of the Joint Matriculation Board version of A-level English Language (for an example of a paper, and an account of developments in this area, see Keith 1990). Among other activities, this work involved the comparative study of dialect variety. Similar investigations were encouraged in work within multilingual schools by Richmond (1982), Houlton (1985), and others. The growth of interest in comparative and investigative approaches to language was also fostered in the 1980s by the Language Awareness' movement, which, as the name implies, aimed to increase pupils' awareness of language throughout the secondary curriculum (Hawkins 1984).

8. The Situation in the 1990s and Beyond: The Return of Traditional Grammar

At the end of the 1980s, despite a political climate which favored a return to the traditional grammar approach, two official reports which focused on this topic for England and Wales, and the equivalent official publication for Scotland (Scottish Office Education Department 1991), put forward a view which was closer to the 'explicit' strand of the language-study-based approach. They advocated that teachers should have a broadly based and accurate knowledge of language, and gave explicit guidance as to which concepts and terms should be introduced at which stages. There is in fact a surprising degree of unanimity among all the official reports on the value of what the Scottish bulletin called 'a grammar of mention,' although Bullock (Department of Education and Science 1975) adopted a rather more 'implicit' stance.

After the LINC materials were produced, the British government of the time refused to publish or support them, presumably because they were not sufficiently traditional in language model or methodology. From that point onward, government policy

in this area was aimed at ensuring that all primary teachers and all secondary English specialists in England and Wales would teach traditional grammar, directed at developing competence in standard English, on a regular and systematic basis. Williamson and Hardman (1995: 118) say of the revisions in the National Curriculum Revised Orders that 'they place more emphasis on the need to teach standard spoken and written English and the rules of English grammar to all pupils.' They go on to add that the revisions 'also include more explicit grammatical terminology as part of a 'parts of speech' approach than was the case in the original Cox curriculum.' After several proposals and revisions, then, the final text of the English Order was published in January 1995, in a form which related the development of language to the study and use of texts in context (including pupils' own texts) but which also specified the grammatical terms and concepts which would be taught.

Part of the Order for Writing at Key Stage 2 and Writing at Key Stages 3 and 4 (ages 11–16) is included here, to give an impression of the approach to grammar which is being proposed (QCA 1998: 22, 24). In the full Order much more is included about vocabulary and about the varieties and historical development of English.

Writing (Key Stage 2) (as in the Order)
(a) Pupils should be given opportunities to reflect on their use of language, beginning to differentiate between spoken and written forms. They should be given opportunities to consider how written standard English varies in degrees of formality.
(b) Pupils should be given opportunities to develop their understanding of the grammar of complex sentences, including clauses and phrases. They should be taught how to use paragraphs, linking sentences together coherently. They should be taught to use the standard written forms of nouns, pronouns, verbs, adjectives, adverbs, prepositions, conjunctions, and verb tenses.

Writing (Key Stages 3 and 4)
(a) Pupils should be encouraged to be confident in the use of formal and informal written and standard English, except the grammatical, lexical, and orthographic features of standard English, except where nonstandard forms are required for the effect or technical reasons. They should be taught about the variation in the written forms and how these differ from spoken forms and dialects.
(b) Pupils should be encouraged to broaden their understanding of the principles of sentence grammar and be taught to organize whole

texts effectively. Pupils should be given opportunities to analyze their own writing, reflecting on the meaning and clarity of individual sentences, using appropriate terminology, and so be given opportunities to learn about:

> *discourse structure*—the structure of whole texts; paragraph structure; how different types of paragraph are formed, openings and closings in different kinds of writing;
> *phrase, clause, and sentence structure*—the use of complex grammatical structures and the linking of structures through appropriate connectives; the use of main and subordinate clauses and phrases;
> *words*—components including stem, prefix, suffix, inflection; grammatical functions of nouns, verbs, adjectives, adverbs, pronouns, prepositions, conjunctions, and demonstratives;
> *punctuation*—the use of the full range of punctuation marks.

Perhaps surprisingly, the change of government in Britain in May 1997 did not lead to any appreciable change in the above policy; in fact, the move towards a situation in which all teachers in England and Wales taught grammar was probably accelerated, and certainly made more effective. One key feature of the new government's approach was the National Literacy Strategy, initiated in August 1997. The central component of this strategy was the setting up of the National Literacy Hour, wherein all primary schools—apart from those which could demonstrate an equally worthwhile alternative strategy—would set aside one hour per day in each class for specified language development activities embracing reading, writing, and involving whole-class teaching, together with group and individual work. Within this structured daily hour there was to be, at Key Stage 2, approximately 15 minutes of whole class teaching devoted to a balance over the term of focused word work or sentence work, and 15 minutes on shared text work (reading and writing). There would also be 20 minutes devoted to individual and group work on texts or word and sentence work and 10 minutes whole-class work on review of points covered. Each term's work is set out in a series of closely linked objectives for a particular range of reading and writing, organised in three 'strands' for word level; sentence level and text level. 'Sentence Level' involves 'grammatical awareness and sentence construction and punctuation' (DfEE 1998).

Several other government-inspired initiatives were developed by various official agencies from 1995, with the aim of developing teachers' language awareness, particularly in relation to grammar. The first of these involved the survey of teachers' confidence and awareness of language in relation to teaching, carried out by the School Curriculum and Assessment Authority from 1995 to 1997 (QCA 1998). Secondly, the Teacher Training Agency (TTA) produced a series of papers aimed at enabling teachers to assess their own level of awareness and competence in language teaching (TTA 1998). Thirdly, the Qualifications and Curriculum Authority (QCA) produced a booklet on grammar for teachers, 'The grammar papers,' and these papers have frequently been referred to in this article (QCA 1998). The central principles for their approach, as described in a later QCA booklet (QCA 1999) were that:

(a) explicit grammar teaching should be integrated into the overall English curriculum;
(b) grammar teaching should have a well-defined focus;
(c) systematic planning should ensure progression and development over time;
(d) grammatical features of texts should be related to function, effect and meaning.

The second QCA publication referred to above, 'Not whether but how' (QCA 1999), 'explores the implications of the principles set out in 'The grammar papers' and gives examples of how the principles can be put into practice. It offers further guidance on the teaching of grammar at Key Stages 3 and 4 but does not attempt to provide complete answers in an area where much remains to be developed.' Part 1, 'Developing pupils' explicit grammatical knowledge,' provides 'help to teachers in implementing the practical implications of the principles outlined above.... Each of the contributors consider whether there is a core grammar or set of grammatical terms and relationships that all pupils need to know.' Part 2, 'Approaches to planning and teaching grammar,' shows 'how English departments can review their existing curriculum plans to ensure the systematic coverage of the grammar requirements,' providing practical advice on schemes of work and on individual units, as well as on the needs of less confident writers, pupils for whom English is an additional language, and on the analysis of children's writing.

With reference to Key Stages 1 and 2, as mentioned in 7 above, the National Literacy Strategy in primary schools was supported by a national programme of in-service training, which was based on a series of published training materials of which the most relevant here is Module 3, 'Sentence Level Work' (DfEE 1998b). The NLS training sessions were followed by the production in 2000 of a website for teachers, the 'Standards Site: Literacy,' as part of the 'Raising Standards' initiative. The online training course on this site which is relevant to this article is 'Grammatical Knowledge for teachers',

729

which provides self-study materials to enable teachers to increase their grammatical awareness (DfEE 2000).

The second initiative aimed at raising teachers' language awareness was the Initial Teacher Training National Curriculum for primary English. This is set out in three sections:

> *Section A*: what trainee teachers must be taught during their training courses in order to understand how to develop children's abilities to use English effectively.
> *Section B*: the teaching and assessment methods which trainee teachers must be taught and be able to use.
> *Section C*: the knowledge and understanding of English which trainee teachers need to underpin their teaching of primary English.

9. The Situation in the 1990s and Beyond: Developments in Scotland

The Scottish guidelines for English Language (SOEID 1991) advocated a staged introduction to grammatical terms, identified within the Knowledge about Language strand of the Writing outcome. Pupils would be expected to be familiar with the main parts of speech by Level D (years 4–6) and with 'subject', 'predicate,' and 'clause' by Level E (years 6–9). Terms for aspects of textual organization, namely, 'paragraph,' 'topic sentence,' 'evidence,' were also required by Level E. The guidelines state that 'the terms included in this strand will enable pupils to understand aspects of the activities in the (other) strands (of Writing). They should be taught within the contexts of such activities and reinforced through regular use' (SOEID 1991: 48). Thus, the approach as set out in the guidelines is broadly similar to that of the English Order for England and Wales, but without the in depth prescription of the details and phasing of KAL which is seen in the National Literacy Strategy objectives (DfEE 1998).

Moreover, in 1998, in the teaching approaches suggested for the new upper secondary National Qualifications examination framework for English (originally known as 'Higher Still'), a broadly similar approach to that set out in the National Curriculum English Order was proposed. For example, with reference to the Intermediate Level 2 (Pre higher) and Higher assessments, the teaching approaches for Literacy Study suggest that:

> In order to respond with maturity to the language use of others, the student should be familiar with:
> (a) language varieties (for example, register, dialect, standard and nonstandard forms, Scots language forms, changing forms of language);
> (b) classification of language (for example, noun, verb, adjective, adverb, preposition, conjunction, article, sentence, clause, phrase/group);
> (c) conventions of written language;
> (d) critical terminology.

The proposals go on much in the tradition of the grammar of mention: 'Whilst appropriate contexts for developing knowledge may occur as a result of unit/course activities, some direct teaching such as modelling or explanation of concepts may be required. The emphasis should then shift to students demonstrating increasing independence in applying methods taught and knowledge acquired to the texts being studied (Scottish CCC, 1998).

Consultation with HM Inspectors for Schools in Scotland suggested that, in the late 1990s and thereafter, the focus for staff development was to continue along the same lines. For instance, Inspectorate comments on secondary English teaching (SOEID, 1999) advocated that 'the study of literature at all stages [should include] much more discussion of language use and the writer's craft as part of exploring the impact and meaning of texts.'

Moreover, in an initiative reminiscent of the Language Awareness movement, joint staff development resources for Modern Language and English Language, for both primary and secondary sectors, known as the Language into Languages Teaching (LILT) resources, were produced in 2001 (SEED 2001). These would set out common aims for these two modes of language teaching and indicate for the two modes the parallel activities through which these common aims could best be achieved. This approach would, it was hoped, encourage cooperation between teachers with an interest in both mother-tongue and second-language teaching (including both foreign languages and ethnic minority languages). The two sides of the approach would, it was hoped, be complementary in that, for modern language teachers, it would emphasize the importance of language in meaningful contexts and, for mother-tongue teachers, it would emphasize both the identification of specific language forms and their appropriate use in texts, as well as an approach to language learning based on investigations and language games. All these aspects, particularly investigations and games, feature in the modern strategies which will be outlined in Sect. 10. This worthwhile Scottish staff development initiative may well lead to the widespread use of a similar investigative approach within English teaching in Scotland.

The LILT resources also include a CD Rom containing a searchable database which defines some 300 language terms in relation to both English and Modern Languages. Teachers can search this database for accurate information on specific aspects of language patterning, together with related strategies relevant to the stage at which they teach. This Scottish resource parallels the self-study training materials for teachers in England and Wales found on the 'Standards: Literacy' website, entitled 'Grammatical Knowledge for Teachers' (DfEE 2000).

10. Early Twenty-First Century Developments: A Commentary

This commentary will consider some of the issues raised by the approaches to school grammar teaching advocated in Britain at the end of the twentieth century, and then outline various specific strategies utilized at that time for raising the level of grammatical awareness in school students.

10.1 The Relevance of Explicit Awareness of Grammar

The QCA paper commenting upon the requirements of the English Order (QCA 1998), in common with most of the other official pronouncements mentioned in this article, makes a clear distinction between 'implicit knowledge' and 'explicit knowledge' of language. It goes on to trace the process by which pupils are enabled through *analysis* of the *functions* and *effects* of linguistic features in texts, to develop *explicit knowledge*.

Unfortunately, this central distinction between implicit and explicit knowledge does not always feature clearly in the actual language of the English Order, at least for Key Stage 2. Yet it is a crucial issue for teaching of grammar, as the Scottish bulletin clearly explains. It is reasonable for Carter to view the growth of explicit knowledge as a process which interacts and overlaps with implicit knowledge, but it is unhelpful to blur the distinction or ignore it, as such a stance probably leads to the folk-linguistic myth that we cannot really expect competence in grammar unless we 'know the grammar.'

10.2 Conscious and Unconscious Use of Language

This aspect raises another pertinent issue: that if explicit knowledge of language is to influence use of language, that use of language must be, or become, conscious, at least for a time. Yet Halliday (1988) reminds us that the complex, dynamic, creative language that we use unconsciously in spontaneous speech depends upon our unconscious grasp of grammar; whereas the typical language of writing or prepared speech depends upon lexis and a dense but usually less complex grammar, and is usually more of a conscious process. Halliday sums up his view thus: 'Our ability to use language depends critically on our not being conscious of doing so—which is the truth that every language learner has to discover, and the contradiction from which every language teacher has to escape' (Halliday 1988: 38).

Certainly, the production of effective writing may become a largely unconscious process for us, but in order to achieve this, we need to have internalized all the language features which would make that writing appropriate. Thus, features of written language can be identified consciously (with or without labeling) and then become internalized through practice within

meaningful contexts, so that their use becomes unconscious within the writing process. Yet the central aim of teaching grammar in relation to writing is to extend pupils' writing skills by the use of certain grammatical features which are appropriate or effective within writing contexts—and to achieve that we may teach pupils to label those features so as to facilitate discussion of their use; the aim is *not* to teach the labeling of those features as an end in itself. At times in the National Literacy Strategy objectives, however, the aim *does* seem to be the acquisition of terminology for features which most pupils can already use unconsciously in speech or writing; for example, the teaching of adverbs (Year 4 Term 1, DfEE 1998: 38) and the focus on word-endings, coupled with the point 'that these are important clues for identifying word classes' (Year 4 Term 2, DfEE 1998: 42).

10.3 The Place of Terminology

The emphasis placed by the English Order and the QCA papers on the need for pupils to use grammatical terminology correctly seems misplaced for various reasons.

(a) The central argument for explicit knowledge about language by pupils is that they should acquire awareness of the nature and functions of the concept or class being focused upon, and not that they should be able to label it with the 'correct' term. It is awareness of the class and its functions that matters, and not that we use an official or traditional label.

An approach which focuses clearly on developing awareness of grammatical concepts and classes, while introducing terminology as and when it makes sense is that outlined by Crinson, describing his work with Year 3 pupils (Crinson 1977–99)

(b) Another difficulty with the approach of the Order to terminology is that different terms may be used by linguists for the 'same' class of units, or they may be subdivided in various ways. For example, the terms 'conjunct,' 'conjunctive,' 'connective,' 'link word,' 'sentence adjunct,' and 'sentence adverbial' can all be found being used to refer to items like 'however,' 'nevertheless,' and 'therefore.'

(c) A related difficulty with the approach to terminology of the Order is that linguists, struggling with the meaningful categorization of the richness of language patterning, often use terminology in a fairly cavalier fashion. Hudson (1992) for instance, presenting grammar to teachers for use in the National Curriculum, makes remarks such as 'This isn't a standard name, but it will do for the time being, and it illustrates the need to invent new terminology at times.' The investigative, creative approach to grammar operated by linguists—so different from the 'tablets of stone' approach to grammar of school grammar syllabuses—means that terms may refer to

aspects of grammar which are, in some important grammatical models, done very differently.

(d) Most pertinent to this discussion, however, is the absence in the proposed terminology of a 'group' or 'phrase' level of structure, having its own distinctive structure and operating in certain ways within the clause.

Crinson's approach, described above, focuses pupils' attention on the structure of noun and verb phrases with their headwords and modifiers operating in various ways. This is one key weakness of the National Literacy Strategy approach: the phrase or group level is not seen as the fulcrum of the patterning of clauses, and phrase structures mainly appear only as incidental extensions of nouns, verbs, adjectives, etc. For all the apparent theoretical neutrality, then, this is a fairly serious theoretical flaw in the National Literacy Strategy approach to grammatical awareness.

(e) In an important article, Halliday raises an even more fundamental objection to the traditional approach to grammatical categories as seen in the National Literacy Strategy, namely that defining formal categories is an essentially limiting and superficial activity which does not allow us access to the lexicogrammatical and semantic richness of the English language.

Obviously we cannot expect pupils to engage in systemic functional linguistics as such, but Halliday's approach suggests that the richness of the grammar cannot be opened up to pupils' awareness by identifying parts of speech but rather by an engagement with how grammatical structures work *within whole texts*, creating certain kinds of meaning appropriate to those texts. Thus it is particularly unfortunate that the textual possibilities which are opened up within the Text Level Strand of the National Literacy Strategy objectives are not supported by a functional or communicative grammar which at least to some extent would allow these possibilities to be explored by pupils in explicit terms. Moreover, the model advocated in the National Literacy Strategy makes no real concessions to the grammar of spoken English, as was advocated in the Cox Report. These deficiencies are not, however, in evidence in the approach for Key Stages 3 and 4 outlined in the QCA booklet (QCA 1999) which will be commented in Sect. 10.5 below.

10.4 Grammar and Texts

The NATE Position Paper on grammar (NATE 1997) emphasizes that the grammar pupils learn about should relate to their own texts: 'Pupils need to develop a vocabulary with which to talk about language, but it is important that it should arise from reflection on their own speaking, reading and writing and not simply be taught out of context' (NATE 1997: 2).

In fact, the National Curriculum and the National Literacy Strategy do take this stance, to some extent. Moreover, the National Literacy Strategy objectives do make links between the development of grammatical awareness and how grammar is utilized in texts, linking with pupil work in reading and writing at text level; for example, Year 4 Term 1, Sentence-level work: 'e.g. narrative in past tense, explanations in present tense, e.g., "when the circuit is ..."' DfEE 1998: 38).

Yet the Sentence-level and the Text-level strands are not helpfully or consistently linked, with the result that the impression is frequently given that the grammar of parts of speech is being taught for its own sake. For instance, adjectives are to be examined and their use encouraged in the writing of descriptive texts as a central feature, whereas it would be preferable to make the central perspective that of the language features which create meaning in descriptive texts rather than, apparently, the other way around, starting with adjectives. Thus, as an alternative approach, the genre of descriptions, including reports, could be regarded as using attributive clauses with linking verbs and adjectives ('my friend is tall') but only as one typical feature of such texts. Certainly, in Year 6 Term 3 of the National Literacy Strategy objectives there is to be revision of 'the language conventions and grammatical features of the different types of text' (DfEE 1998: 54), but nevertheless this linkage, together with the primacy of text, could be more prominently and regularly emphasized, and, as was indicated above, more textual awareness could be created by the use of a more textually-oriented grammar. Yet perhaps the key issue is that identified by Keith in his paper in the QCA (1999) booklet:

> The approach to teaching grammar illustrated here is a combination of functional grammar and traditional concept and terminology. Functional grammar asks what words or groups of words are doing: how are they being used in a particular text and context? Above all it encourages investigation and provides a good starting point for learning concepts for which traditional terminology continues to be sufficient.

10.5 Ways of Teaching Grammar

One of the obvious issues in this area is how we actually teach grammar in terms of strategies and organization. The essential problem is clearly stated in QCA Paper 1:

> How can grammar teaching be systematic and progressive if it is only taught when it arises ... in the context of pupils' own work. At the same time, how can a systematic grammar avoid being a study of form, divorced from the living language it is meant to represent? QCA 1998: 16).

One answer to the problem is provided by Keith in the following terms:

> What is needed for today's students is a semi-contextualised approach in which their explorations can move in and out of contexts in the manner of good scientific learning or learning a second language
>
> (Keith 1994: 69).

Keith's answer to the problem posed by QCA was later exemplified in the papers of the QCA booklet for Key Stages 3 and 4 (QCA 1999). In these papers a wide range of practical examples was provided of how choice of grammatical features such as pronouns, tense, or conjunctions can be focused on in Key Stages 3 and 4 classrooms so as to enable pupils to appreciate aspects of the meaning of texts. Such regular discussion of the function of grammatical concepts leads to familiarization with the relevant terms. These terms can be taught explicitly and systematically, and exemplified in texts in context; they can be taught explicitly as the need for them arises when discussing texts, e.g., grouped together for comparison or as examples of a genre, literary or otherwise; or they can be reinforced as teacher and pupils notice their relevance when discussing texts.

As was indicated in Sect. 8 above, the practical examples in the QCA booklet are accompanied by suggestions for a core of grammatical terms. As the QCA booklet points out:

> The most important thing about these suggested cores is that they are not ends in themselves nor simply inert models or lists of terms and labels. They are shown to be some basic tools with which to investigate patterns, relationships, and meanings in language.

In relation to the systematic planning of grammar teaching, the QCA booklet also provides examples based on the review of schemes of work by various secondary English departments so as to include word and sentence level grammar, including several examples of the revision of individual units.

This kind of semi-contextualized approach was also encouraged in a wide range of grammar courses for schools which appeared after 1990 (Keith 1994, Bain and Bain 1996, Bishop 1996, Bain and Bridgewood 1998). As Keith says, this approach, where issues are introduced and then arise in texts (or vice versa), is normal practice in much Modern Language and EFL teaching (Keith 1994). This kind of two-way approach is demonstrated in the National Literacy Strategy in-service materials and is implied but not made explicit in the National Literacy Strategy objectives.

10.6 Discovery and Problem-solving Approaches

Several linguists writing about the teaching of grammar have objected to the dogmatic and simplistic approach they see in most school grammars and have advocated approaches based on investigating grammar, discovering patterns, or solving problems. Hudson, for instance, suggests that pupils discover for themselves general language patterns in material presented by the teacher. He gives an example of starting to teach word-classes by presenting only the words 'dung,' 'clung,' and 'hung' and having the pupils create as many sentences as possible from these words. From the two possible grammatical combinations the pupils should discover that English words are of at least two different kinds, and thus, as Hudson says 'we have started to discover some word classes' (Hudson 1992: 8–9).

Cameron (1997) and Hudson (1992) show the value of discovering language patterns for oneself and also the problem that the complexity of language at times outstrips the grammatical apparatus that we normally supply to pupils for dealing with it. Yet the fact remains that most teachers will not feel confident in dealing with problematical areas in grammar and thus, despite the strength of these arguments, an approach which focuses on grammatical problems as such is not likely to be embraced by many teachers.

10.7 Focus on Ways of Expressing Meanings

One approach to grammar which is currently much under-used in school grammar courses for mother-tongue teaching is described by Halliday thus:

> A language is interpreted as a system of meanings, accompanied by forms through which meanings can be realised. The question is rather: "how are these meanings to be expressed?" This puts the forms of language in a different perspective: as a means to an end rather than as an end in themselves (Halliday 1994: xiv).

In the 1990s, this kind of approach was more common in second language teaching, where students often consider various ways of expressing the same thing and the different implications that these entail. Yet, in mother-tongue teaching too, this approach would be worthwhile, not least because it would focus on language choice in writing at the point at which that choice is probably most conscious.

10.8 Strategies

In the 1990s, the renewed interest in creating worthwhile grammar activities led to a range of innovative course materials aimed at involving pupils meaningfully. The range of strategies adopted can perhaps be adequately reflected through the list of strategies (slightly adapted and expanded here) provided in Bain and Bridgewood (1998).

> *Playing detectives.* e.g., spotting parts of speech in pupils' own reading and writing.
> *Making lists*, e.g., brainstorming lists of specific parts of speech used in particular contexts, or in

733

Crinson's approach: listing forms of verb tenses used in three different types of text.

Finding patterns and rules from a selected list of words or phrases, e.g., Crinson encouraged pupils to collect verb phrases from two different texts and to try to categorize the types of verb phrase in some way.

Predicting and investigating uses of language for types of text, e.g., uses of types of sentences in different types of texts.

Exploring unexpected uses of language, e.g., exploring the ways in which advertisements and newspaper headlines break patterns and use ambiguity to achieve effect and to attract the reader's attention.

Comparing and contrasting texts, e.g., looking at groups of texts, on the same subject or in different genres, or for different audiences and for different purposes, and considering in each the similarities or differences in vocabulary, sentence structure, and organization.

Messing about with texts, e.g., selecting, changing, adding, and deleting parts of speech in a given text or in pupils' own writing, or reconstructing cut-up texts to determine organizational strategies.

Constructing texts, e.g., following organizational patterns determined through previous investigation of texts, using 'story-boarding' (pictures in sequence) to develop understanding about sentence, paragraph, and narrative structure.

Playing games. There are many activities described in the course materials referred to above which will involve children, through game-playing contexts, in exploring and becoming more aware of aspects of grammatical patterning.

At the end of the twentieth century in England and Wales, then, there was a major initiative centred around the National Curriculum Order for English and the National Literacy Strategy for primary schools. Its purpose was to deliver a language curriculum in which grammatical awareness in relation to texts would be widespread and the fine detail of what was to be taught would be stipulated. While the focus upon text-level work was clearly worthwhile, the grammatical approach which was advocated, with its emphasis upon the identification and labeling of word-classes and its lack of focus on phrase and clause structure, and on the richness of spoken and written language, did not adequately equip pupils to engage with the process of meaning-making in texts. Moreover, since the initiative was to be centralized and developed in a 'top-down' fashion, rather than developing from the involvement of coordinators with area groups of teachers, as had been the LINC Project model, its eventual success was hardly guaranteed.

On the other hand, at the millennium, the initiative for Key Stages 3 and 4, with its text-based approach to grammar teaching and its use of materials from class-room-based research and development by large groups of teachers, seemed to offer a more promising way forward. That way forward was effectively outlined by Carter in his paper in the QCA (1999) booklet:

> Greater classroom attention to grammatical forms can generate a pedagogic climate in which grammar is not a list of terms to be learned but is seen and used as a range of choices and strategies for communication. But, in several senses, a number of boundaries in both theory and in practice have still to be crossed. Properly supported and theorised classroom-based research into the many varied relationships between knowing *about* and knowing *how to use* grammar in reading and writing texts would enable a first major boundary to be crossed.

Gender, Education, and Language
J. Swann

From around the 1970s there has been an increasing interest, in several countries, in gender and language use in educational settings. Such research explores issues of theoretical significance but also has practical relevance for teaching and learning, and for the development of educational policy. This article considers two related issues: gender and classroom language, and boys' and girls' achievements in spoken and written language. It draws particularly on research carried out at school level in English-speaking contexts.

1. Gender and Classroom Language

Early research in the 1970s and 1980s documented patterns of difference and disadvantage in relation to girls' and boys' language behavior in the classroom. Boys were generally observed to have a more competitive speaking style, and girls were more cooperative. Within the classroom, this allowed boys to dominate mixed-gender talk. Boys' interactional dominance was supported by teachers, who often made unnecessary distinctions between girls and boys; accepted certain behavior (such as calling out) from boys but not from girls; and tended not to perceive disparities between contributions from girls and boys. Girls and boys also made different reading choices and wrote in different ways and about different topics. Books and other resources contained more male than female characters and examples, and these characters/examples were also often stereotypically gendered.

Male characters in stories had less restricted roles than female characters; information books often neglected girls' and women's experiences and contributions to society. Even in literacy, an area in which girls tended to do well, it was suggested that

735

girls' achievements in school did not enable them to succeed in later life. Such observations gave rise to a range of equal opportunities initiatives designed, in particular, to provide a more congenial educational environment, and greater educational opportunities, for girls.

More recent research on language and gender, in education as in other settings, has tended to reject a strict 'binary' distinction between female and male language users, emphasizing instead different forms of femininity/masculinity and the intersection between these and other factors—'race,' class, etc. Such research also emphasizes performativity: femininity/masculinity as contextualized practices, rather than fixed attributes. Language, like gender, is seen as inherently context-dependent: there is a greater focus on uncertainty and ambiguity in language use—in the meanings of what language users say and do. Such a model seems incompatible with generalized claims about (educational) gender differences and inequalities, leading to a focus, instead, on the localized 'working out' of certain forms of femininity/masculinity and other aspects of identity.

Some research has also focused on the educational impact of new technology and the alternative textual forms and practices with which this has been associated. At issue here, in relation to gender, is the extent to which electronic communication affords new learning opportunities, and opportunities for new forms of interpersonal relations, and the extent to which it may reinforce traditional gender inequalities. Further research is needed in this area.

2. Girls' and Boys' Educational Achievements

Research carried out over many years on girls' and boys' achievements in English/language-related activities suggests that girls perform better than boys, on average, in tests of verbal ability; in school, they learn to read earlier; and there are fewer girls than boys in remedial reading programs. Surveys of older children have also found that girls perform better than do boys on many language-related tasks. In terms of educational outcomes, girls have traditionally done well in language-related subjects in public examinations and, in many countries, their performance in these areas has increased relative to boys. Interpreting such findings has not been without problems. While general patterns have been identified there are also differences between tests, and changes to test items may produce different results. Tests measure a variety of aspects of language; it is by no means clear that these can be bundled together into a single coherent category such as 'verbal ability.' General patterns also mask the fact that there are substantial differences in performance between boys and between girls, and educational performance is not necessarily consistent with post-school achieve-

ments (in employment, for instance, the 'glass ceiling' is still in evidence in many contexts).

Whilst there have always been concerns about boys' performance in English and in language generally, this surfaced as a major issue during the 1990s and into the 2000s as part of a broader concern about boys' educational 'underachievement.' According to some commentators, this has attained the status of a 'globalized moral panic': it has sometimes been related to a widespread 'crisis of masculinity.' Such concerns have given rise to a number of measures designed to increase boys' motivation and enable them to do better in school. The focus on boys' educational 'underachievement' tends to prioritize boys' interests over girls' and this has led to fears that girls' interests will be marginalized. Some measures designed to increase boys' motivation and achievement bear more than a passing resemblance to educational practices during the 1970s and 1980s that were found to disadvantage girls. It has not been clear how language and gender researchers should respond to this. While some researchers have tried to engage with 'underachievement' on their own terms (e.g., drawing on contemporary research to produce materials that will encourage boys to explore and critique different forms of masculinity), others have maintained a more oppositional stance (e.g., attempting to challenge the whole notion of 'underachievement' and its ideological underpinnings).

Home Language and School Language
M. MacLure

When children start school they are already experienced communicators. They are also experienced learners. These two accomplishments are not unconnected: in the preschool years, children learn through language in their interactions with other people. They learn by asking and answering questions, exploring ideas, playing with language through jokes and rhymes, testing out hunches, recalling the past and anticipating the future, sharing feelings and interests through stories, comparing qualities and attributes. Children bring knowledge and expertise to school with them, therefore; and most importantly, they know how to get more. Yet some continue to thrive as learners in school, and some do not. This has led researchers to ask whether children's experience of language at home might contribute to their success or failure at school.

1. 'Mismatch' Explanations of Educational Failure

The basic assumption has been that of a 'mismatch,' for some children, between the language they have become accustomed to at home, and the communicative norms of the classroom. Some children, it is argued, start school poorly equipped to cope with the language of the classroom, and consequently, poorly equipped to learn. There are two rather different versions of that assumption, which have been called 'deficit' and 'difference' approaches. 'Deficit' theories locate the 'problem' in the home, suggesting that some children receive an impoverished range of communicative experiences, which leaves them at a disadvantage in school. 'Difference' theories speak of difference rather than deficit. Without making value judgments, they suggest that there is nonetheless a wider gap between home and school language for some children than for others (see *Educational Failure*).

There may seem to be little difference between these two explanations, since both are based on the notion of a mismatch between children's existing experience of language and the unfamiliar practices of the school. But they tend to be associated with different practical outcomes. Deficit theories often inspire remedial programs designed to 'enrich' the experiences of those children who are felt to be 'linguistically deprived' at home. Difference theories tend to focus strategically on the language of the school, and to propose strategies for broadening its communicative norms so that they are accessible to a wider range of children.

2. What's the Problem? Dimensions of Difference Between Home and School Language

Almost every conceivable aspect of language has been the focus, at one time or another, of research into home and school language. Early studies (now considered of limited interest), tended to concentrate on syntax, and to suggest that the language of some children (usually lower- or working-class children: see below) was syntactically less complex than that of others. More recent work has tended to focus either upon the meanings that children are able to convey, or their understanding of the special rules that govern classroom interaction (see *Spoken Language in the Classroom*).

2.1 Abstractness and 'Higher-order' Thinking

One recurring concern has been children's ability to use language which is not tied to the immediate physical context. When children first learn to communicate, they talk mainly about familiar people, objects, and events. Gradually, they begin to use language in a more 'abstract' and decontextualized way: to reflect on the past, to anticipate the future, to contemplate the world from the viewpoint of other people, and to speculate about possible as well as actual worlds. These latter activities are highly valued in Western education systems, as are the reasoning skills that they involve, such as hypothesizing, interpreting, and evaluating. These are often referred to as 'higher-order' skills, and they are generally held to underpin learning. It has been suggested that some children do not experience much 'abstract' language of this kind at home, and that they therefore start from behind when they get to school.

Some of the assumptions behind such suggestions have been challenged. It has been argued that

737

classroom language is no less 'context bound' than any other kind of language, and that teachers and pupils have to work together, just as parents and their children do, to establish a shared context for their talk. Moreover, some would argue, the so-called 'higher-order' intellectual skills that are valued in school are also present—but often overlooked—in much of the 'informal' talk that goes on in most homes.

2.2 Classroom Discourse and Cultural Diversity

Another strand of work takes a cultural perspective, looking at classroom language as a special kind of discourse, with its own rules about who talks to whom, about how communication should be organized, and about what counts as valid knowledge. Children are required to know, for instance, how (and when) to answer teachers' questions, what will count as a 'relevant' contribution to discussions, how to take part in story-telling sessions, etc. Failure, on this reading, stems from an inability (or unwillingness) to observe the norms of classroom talk. Cultural explanations often focus on the school, rather than the home, as the locus of failure: children fail because their cultural practices and values are not recognized by the monocultural, White, middle-class orientation of schools.

3. Social Dimensions of Success and Failure at School: Class, Ethnicity, and Gender

Educational underachievement tends, in Western cultures, to be linked with sociological factors such as class, race, or gender. It is not surprising, therefore, that such factors have also been prominent in the language-related research. 'Social class' has received by far the most attention. Bernstein (see *Educational Failure*) claimed that the language of working-class (English) families differs at all levels (phonological, syntactic, semantic, and pragmatic) from that of the middle classes, because of their different culture, and hence the different values, beliefs, and purposes that each class encodes in its communicative practices. Bernstein claimed to be making no value judgments in describing working- and middle-class language in terms of two idealized 'codes'—'restricted' and 'elaborated', respectively. However, his work, which has been very influential amongst educationalists, has often been interpreted as a deficit theory of working-class language, and his two codes have entered the language of teacher education. Tough's functional analysis (1973) is another example of a class-based deficit account. Heath (1983), on the other hand, offers a cultural, rather than a deficit, analysis of why working-class and Black children in the USA may be failing in school.

Ethnicity has also been a focus for research. Here, the predominant trend has been towards cultural explanations which hold schools to account for their failure to value the linguistic practices of children from ethnic minority cultures (see *Ebonics and African American Vernacular English*).

Gender, too, has been studied from a cultural perspective. Girls, it has been argued, face obstacles as learners because boys are allowed to dominate classroom interaction. If learning takes place through active participation in classroom talk, girls must be losing out, because they tend to get a smaller share of the interactional 'cake.' Some would go even further, and argue that the value attached to 'abstract' argument and 'impartial' judgment in the education system endorses a masculine orientation which devalues the more person-centered, affective tendencies of girls and women.

4. Reversing the Polarities: Should School be More Like Home?

Parents of young children have been accorded a good deal of the blame—by deficit theorists at least—for failing to 'equip' their children for the demands of school-based learning. There is an alternative view, however, which holds that teachers could learn a good deal from parents, and that children learn most successfully under conditions which resemble those of the home. Parents, according to Bruner (1983), are expert providers of 'scaffolds' for their children's learning: they are able to tune in to their children's interests, willing to let their children take the lead in conversations, yet ready to provide support and guidance at critical moments. If teachers could be more like parents in this respect, it is suggested, learning through language might be more effortless for all children.

5. Future Work

There is no general agreement on the relationship between language and educational success or failure. The most urgent need is for more empirical studies both of home and school language.

Literacy
C. J. Daswani

The term 'literacy' has acquired connotations that go beyond its dictionary meaning of 'the state or condition of being literate'; the word 'literate' being used for a person who is able to read and write. In a very general sense this basic connotation of reading and writing remains, but in the contemporary context the additional connotations of the term derive from the changing demands made on literacy both in the industrialized and the developing world.

In the industrialized countries more and more literate individuals are finding their literacy insufficient for the demands made on it both in the place of work and in civic life. In the developing countries, on the other hand, literacy derives its added connotation in the context of widespread illiteracy which continues to deprive a large number of people of the advantages that accrue through formal education. Furthermore, the more recent specialized uses of literacy have led to newer coinages such as 'computer literacy' and 'legal literacy.'

Imparting of literacy is no longer limited to the school and college curriculum. It is a concern in which the politician, the planner, the development economist, the social activist, and the social scientist all have a part to play.

1. No Single Definition
The multiple connotations of literacy make it difficult, if not impossible, to find an acceptable definition of the term. Even the basic connotation of reading and writing does not help because there is no agreement on what abilities and knowledge would count as literacy. In other words, there is no agreement on the level(s) of literacy that need be achieved for a person to qualify as literate. This is because each society or culture determines specific levels of literacy competence which should be achieved by its members.

To accommodate different cultural contexts and demands, the notion of 'functional literacy' has been introduced. A person is considered to be functionally literate if s/he is able to carry out activities where a certain level of literacy is assumed to be necessary within the culture. However, the notion does not help in the measurement of literacy. No society requires uniform levels of literacy from all its members. Hence functional levels differ from one subgroup to another within the same culture, making it difficult for setting up norms of achievement. It is difficult enough to measure levels of literacy or functional literacy within one cultural context, it is impossible to establish norms that will provide comparative assessment across cultures.

A part of the difficulty of definition comes from the fact that some scholars view literacy in the sociocultural perspective, while others view it as a measurable phenomenon in terms of specific skills and abilities. Although no single acceptable definition of literacy is available at present, there is clearly a need for a broad consensus on what literacy is. Only a clearer definition of the concept will ensure worldwide agreement and action.

2. Levels of Literacy
There is very little empirical research on levels of literacy. In the area of adult literacy, in fact, there is no reliable study to indicate the levels of literacy that adults can or should achieve. There is, however, some theoretical literature, supported by limited research, in the area of reading levels achieved within the formal educational system in the school and college. It must be pointed out that even these studies relate to specific cultural contexts.

Generally six reading levels or stages are identified which a child masters through the school and college, beginning with the prereading stage and ending with the mature and expert reading stage. Normally the formal school learner takes 12 years at school and several years at college to cover the entire range of reading abilities.

The first three stages of reading coincide roughly with the first three grades in school. In these stages the learner progresses from prereading to decoding through to fluency. At this level the reader is able to read what s/he already knows in terms of both language and knowledge. At the fourth stage of reading, which corresponds with school grades 4 to 8, the reader is able to use his reading ability to acquire new knowledge. Through this stage the reader is able to gradually cope with texts that are complicated and carry new information. During reading stage five, corresponding to high school grades 9 to 12, the reader acquires the ability to read a range of complex materials critically. In the final stage which begins at college and goes beyond, the reader becomes a mature reader, able to read for a variety of purposes—professional, personal, and civic.

3. Childhood and Adult Literacy
Children normally require 12 years (of grade school) to master reading at a level where they are able to comprehend complex texts and to make inferences. The progression from prereading to grade 12 reading is slow. Children take up to 3 years to acquire reading abilities to read texts that are within their own

739

vocabulary range. To be able to read texts using new words and knowledge takes much longer.

In the early stages the child reader is able to read words that are common, familiar, concrete, and short. The sentences are simple and the ideas and concepts in the text are common and concrete. As the reader progresses to higher reading stages, the vocabulary becomes more difficult, unfamiliar, and abstract. The sentences become longer and complex, and the ideas and concepts more abstract. The beginning reader has limited world knowledge. As they progress through the reading stages they acquire newer knowledge which facilitates higher reading abilities.

Does the adult reader progress through the same reading stages as a child does? There is no clear answer to this question. Some experts believe that the progression for the child and the adult reader is essentially the same. It is true that an adult reader has a larger vocabulary and more world knowledge. Yet the adult goes through the same stages of reading ability as the child. It has been argued that adults may achieve the initial reading stages of prereading, decoding, and fluency faster than children, but reading with critical comprehension takes much longer despite the knowledge base of the adult reader. Other experts believe that adults (and children) have to be imparted new knowledge and concepts before they can become fluent readers.

One of the major problems arises from the fact that all adults who need to acquire reading (or literacy) skills do not begin at the same level. Some adults (in some cultures) may have acquired basic literacy skills which they have forgotten or which are no longer functional in their contexts. In other situations, the adult learners may have had no prior literacy training. It is therefore difficult to assess the direction and rate of progression in the case of adult readers.

Another problem arises from the paucity of tests for measuring adult reading success. While many measurement tools exist for measuring school and college level reading abilities, scientifically devised tests for measuring adult reading achievements are almost nonexistent. Part of the reason for the lack of tests for adults stems from the reluctance to subject adult learners to formal achievement tests of any kind. However, there is general agreement that for durable reading abilities, adult learners need to achieve reading levels equivalent to grade 12 of the school reading grades. An adult reader who achieves reading abilities of grade 8 is perhaps functional but not a mature reader.

4. Reading and Writing

Although skills of reading and writing must be seen as equally significant in acquisition of literacy, most studies on literacy focus mainly on reading. Consequently, while a considerable amount of data is available on the acquisition of reading both by children and adults, not enough is known about the acquisition of writing skills. It is nevertheless the case that a large number of studies on reading provide some insights in the graphological aspects of writing systems. Such studies relate to the measurement of difficulties faced by beginning readers in recognition of written symbols. For instance, children's memorization of letters and their combinations in words is influenced by the shapes of letters. Such problems are relatable to the kind of script or writing system employed by a particular language.

However, the problems of recognition of letters or characters are significantly different from those of reproduction when a beginning learner has to write the shapes of letters or characters. It is generally believed that children find it easier to recognize letters and characters but find it difficult to write them. Most researchers on acquisition of writing skills concentrate on the problems faced by children. There is very little information on how adults acquire writing skills.

Some researchers working in this area have studied the compositional and rhetorical aspects of writing rather than the purely motor aspects of reproduction of letters or characters. There is some evidence that in addition to the motor act of producing a written test, a learner has to acquire a set of conventions and norms for discourse production; norms which are culturally determined and differ from one cultural group to another. Even these studies deal with writing skills of children and adolescents.

In several adult literacy programs measurable goals of reading and writing are specified and an adult illiterate is declared to have become literate only when he demonstrates his ability to read and write according to the specified norms. However, there is no systematic research on the problems an adult encounters in requiring these skills.

5. Literacy and Language

It is generally agreed that literacy levels are linked to language competence. At the same time there is some evidence to show that literacy practice leads to better language control and critical thinking. Most literacy programs begin with what the learner knows of their language. A child is said to know about 5000 words in its mother tongue before beginning to learn how to read. On becoming literate, they learn to recognize known words in print. Gradually, with the help of known words, they learn new and unknown words while reading at higher levels. In the process s/he also learns to comprehend more complex language structure used in higher level texts. It has been demonstrated that vocabulary range and reading abilities are interlinked.

The adult learner may have the initial advantage, over the young learner, of a larger vocabulary and

more complex grammatical structure. But the mutual advancement of literacy and language control operates equally in the case of the adult. Critical reasoning is enhanced with higher reading abilities.

It is universally accepted that literacy is best imparted in the mother tongue. This is not difficult to appreciate because when literacy is in the mother tongue, the learner is merely acquiring the new skills of reading and writing without having to master new language structure and vocabulary. However, in many situations literacy is imparted in a language other than the mother tongue of the learner. This is especially so in the case of adults who have to acquire literacy skills in a language not their own, as in the case of immigrants.

In many multilingual countries children often have to learn to read and write in a language that is not their mother tongue. In such cases the rate of literacy learning is impeded since the learners do not control the language of literacy. Similar problems may also arise in situations where children speak a nonstandard dialect at home and are taught to read and write in the school through the standard language.

In Third World countries where large populations of adult illiterates have to be taught literacy, the choice of the language of literacy becomes very important. In most cases the adult illiterates may be speakers of unwritten languages and dialects which are used for limited in-group oral communication. The goal of literacy in such situations is to enable the adults to function effectively in the larger contexts of work and development. The language in such contexts is invariably the regional or national standard language which may not even be related to the mother tongue of the learner. The willingness to become literate in a second or foreign language correlates with the attitudes of the learner and the community. It is known that in some contexts the learners demand literacy in a second or foreign language for its prestige in the total communication network.

6. Literacy and Oracy

The relationship between the oral and literate modes of language is not easy to understand. Cognitively as well as pedagogically the oral mode is said to depend on the skills of listening and speaking, and the literate mode on the skills of reading and writing. But the skill correlation is not all. There are other complex relationships between the oral mode or oracy and the literate mode or literacy.

It has been argued by some that development of oracy and literacy both follow universal laws of learning as well as universal principles of language learning. In such a view oracy and literacy are seen as varieties of language behavior and, hence, both are believed to share many patterns which should be evident in the processes in which oracy and literacy

are acquired. The argument, that there are many speech communities without a written mode of communication, is not considered valid, for it is claimed that if they were to become literate the acquisition of literacy in such communities would follow the same path as in other literate cultures.

There is also the opposite opinion that literacy is not a universal of human life. According to this view literacy is not governed by cognitive universals which develop naturally without any special environment. Even in literate communities, many individuals remain illiterate, which would point to literacy not being parallel to oracy (see *Oracy*). It is also noted that human beings acquire oracy during the initial stages of biological and cognitive development while literacy requires a special environment. However, it may also be mentioned that there are instances when children who have become removed from human language during their infancy have failed to acquire oracy.

There is also a viewpoint that every language community determines the domains in which oracy and literacy may operate, either separately or in conjunction with each other. In fact, both oracy and literacy in themselves reflect a great deal of variety much like different language styles. In other words, in any given communication situation an individual not only has the choice between the oral or literate mode, but within each has several choices which are governed by the total communication setting.

If oracy and literacy are interlinked, it is worth noting that as literacy has gained during the twentieth century, oracy has declined. Many cultures that had vibrant oral traditions have become marginalized in the face of the increased value given to literacy. In fact, limited oracy has never attracted as much attention as limited literacy has since World War II.

Linguists have, unfortunately, not paid as much attention to literacy as they might have. For the linguist, speech or oracy has remained the main focus. Psycholinguists, and in some measure sociolinguists, have addressed the problem of literacy more than the linguist has.

7. Literacy and Illiteracy

Many countries in the Third World have chosen to link economic development to literacy. Following the example of the industrialized countries many of these developing countries have opted for universal literacy as a goal in their effort to evolve egalitarian and industrialized societies. Many of these countries have traditional cultures where literacy has limited and specific functions, and literacy has been the domain of a small number of individuals in the community. To attain the goal of universal literacy in such cultures is not easy. Illiterate adults in such societies do not readily perceive the benefits of literacy.

741

Nevertheless, the models of development adopted by these countries require some level of literacy. While many of these societies are slowly moving in the direction of increased childhood literacy, the adult population continues to make up the bulk of the illiterates. Unfortunately, in the absence of universal elementary and high school education, the number of illiterate adults has continually grown.

In many of these countries the educated and political elites have sought to bring about a change in the literacy situation through what are known as literacy campaigns. Many of these countries perceive illiteracy as a disease which must be eradicated. Such campaigns are launched with a great deal of fervor and commitment. However, it is not clear how such campaigns can actually end illiteracy. Often the methodologies employed are more to engender motivation for literacy rather than ensure literacy skills amongst the illiterate learners. Also, functional literacy, rather than higher literacy, is the goal of such campaigns.

There is very little research data to make any claims on behalf of such campaigns. It is not known how far such campaigns succeed, and more importantly, whether the newly literate adults are able to utilize their skills. Often, there is relapse into illiteracy since either the new literate does not find his skills of use in his cultural context, or the skills acquired have not been of the order where automaticity has been achieved. As with other kinds of skill learning, stable literacy is achieved only when the learners achieve levels beyond the basic levels.

8. World Literacy

Literacy is a global issue. The Appendix to this article provides basic statistical information about world literacy, reproduced, with permission, from the UNESCO Statistical Yearbook 1991.

The industrialized countries are concerned about their citizens who do not have enough literacy to cope with the increasing demands made on literacy by technology. The number of people who cannot advance in their careers for want of functional literacy is on the increase.

In the developing countries, however, the literacy figures are far below those in the industrialized world. The concern in these countries is with universal elementary education. The illiteracy figures in some of these countries are above 50 percent. While the school literacy figures are slowly mounting in these countries, on account of rapid population growth the absolute number of illiterate adults is ever growing. According to estimates the total number of adult illiterates will touch the one billion mark by the end of the twentieth century. Most of these illiterates will be in the developing countries in Asia, the Middle East, Africa, and Latin America.

The paradox the world faces is that while in the highly literate societies in the industrialized world the levels of literacy are not high enough, in the developing world not enough people have acquired even basic literacy levels. Identifiable sections of the society in these countries have traditionally been outside the pale of literacy and continue to be so. In many developing countries women do not receive formal education because their roles in society are not literacy-dependent.

Developing countries have set themselves the goal of achieving universal literacy in their struggle for economic self-dependence. Yet, there is no evidence that literacy alone is a critical determinant in economic development. In the global context literacy should be seen as one of the factors in achieving a world order which ensures human rights to all. Literacy is a component in the movement of education for all. Most countries in the world are committed to ensuring that all children and adults should have access to education for better and effective participation in their chosen fields of activity in their cultures.

9. Future of Literacy

While both the industrialized and the developing countries strive for world literacy, the future of literacy continues to be full of paradoxes and contradictions. In the industrialized world the present concern is with coping with the high literacy demands of a technologically oriented society. At the same time, technology itself is likely to take on some of the demands on literacy, making it possible for people to function at lower levels of literacy. In the developing countries the goal of universal literacy entails increased outlays on education. At the same time the developing societies have not changed enough to accommodate the concomitant socio-cultural impact of universal literacy.

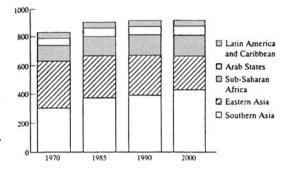
The question that arises is: will a fully literate world be without stratification? The chances are


Figure 1. Developing countries, illiterate population aged 15 years and over (in millions).

that even if all human beings are made literate, there will always be markers of individual and group differences. Language has always played a major role in the creation and maintenance of such distinctions.

The impact of literacy in the near future can be very significant. The role of the educator, the social scientist and the policy maker will become more crucial for finding common and acceptable solutions to problems of literacy. For the linguist literacy studies may provide meaningful insights into the structure of the human mind, language universals, and the relationship between oracy and literacy.

APPENDIX (reproduced with kind permission from *The UNESCO Statistical Yearbook 1991*. UNESCO, Paris)
Literacy: Trends and Prospects at the World and Regional Level
1. Significant Facts

- Of the 4294 million inhabitants aged 15 and over living on our planet in 2000, almost 1 billion, or 21.8 percent will know neither how to read nor to write.
- Between 1970 and 1985 the number of illiterates grew by approximately 59 million. Since 1985, the number has remained stable, and there should only be a slight decrease by 2000.
- Relatively speaking, compared to the adult population, this stability in the number of illiterates means a decrease in the rate of illiteracy: 38.5 percent in 1970, 26.5 percent in 1990 and 21.8 percent in 2000.
- Almost all the illiterate population is found, indeed, will continue to be found, in the

developing countries: 917 million in 1990 or 34.9 percent of the adult population in these countries.

- At least according to its simplest definition (the inability to read and write a simple text), the amount of illiteracy in developed countries can be considered as negligible: less than 5 percent of the adult population. It is therefore preferable, and more appropriate, in terms of numerical importance, to concentrate the analysis of illiteracy on developing countries.

2. The Developing Countries

- In 1990 in the developing countries taken as a whole, 35 of every 100 adults are illiterate; this proportion which was above 50 percent in 1970 could decrease to 28 percent in 2000.
- Taking the least developed countries on their own, the size of the illiteracy rate will not decrease very quickly and in 2000 one of every two adults will still be illiterate in these countries.
- The numerical predominance of Eastern Asian and Southern Asian developing countries is evident: 677 million illiterates in 1990, that is, 71 percent of the world's total, a relative figure which should last until the year 2000. If these two subregions are considered separately, Eastern Asian countries will experience a drop in the number of illiterates and in the rate of illiteracy, to 23.8 percent in 1990 and 17.2 percent by the year 2000. Of course, this evolution is mainly attributable to demographic trends and the development of schooling in China which,

Latin America/Caribbean	164.0	252.1	286.9	362.7	43.0	44.6	43.9	41.7
Eastern Asia	692.5	1036.3	1171.3	1375.1	324.1	295.3	278.8	236.5
Southern Asia	440.0	648.4	738.6	952.2	302.3	374.3	398.1	437.1
Least developed countries	135.2	212.3	245.4	333.4	104.8	138.4	143.2	170.1
Developed countries	770.8	918.6	954.6	1020.9	47.8	42.3	31.5	15.7
Classification by continents								
Africa	200.3	305.2	354.3	485.5	152.6	171.8	177.5	186.4
America	326.0	459.4	503.6	598.1	52.8	54.7	50.4	42.5
Asia	1253.9	1846.8	2088.7	2538.3	652.0	694.4	699.7	695.5
Europe and USSR	518.1	597.0	614.6	649.3	31.1	26.9	19.1	9.7
Oceania	13.1	17.8	19.4	22.3	1.5	1.7	1.4	1.2

because of its size, is predominant in this subregion.

- In Southern Asia, where demographically important countries are also to be found, one adult out of two is illiterate; despite a significant decrease between 1985 and the year 2000, the illiteracy rate (45.9 percent) will still be higher than in all other regions.
- Sub-Saharan Africa in 1990 will have 139 million illiterate inhabitants, representing more than 14 percent of the world's total. Concerning the adult population, here as in Southern Asia, one adult out of two is illiterate. However, if the trends revealed by this assessment are confirmed, this region's illiteracy rate will experience the largest decrease: 40.3 percent in the year 2000 as opposed to 59.2 percent in 1985.
- Although the 61 million illiterates in the Arab States account for only 6 percent of the world total, they represent nearly 50 percent of the adult population of this group of countries. As in the case of Sub-Saharan Africa, this rate should drop sharply to 38 percent by the year 2000.
- Lastly of the developing countries, the region of Latin America and the Caribbean has the smallest number of illiterates and the lowest illiteracy rate, that is, only 11.5 percent by the year 2000.
- In terms of perspectives for the year 2000, these figures indicate that although the illiteracy rates will drop to a relatively low level in Latin America and the Caribbean, and in Eastern Asia, the magnitude of the problem will persist in other regions (Southern Asia, Sub-Saharan Africa and the Arab States).

3. Illiteracy by Sex

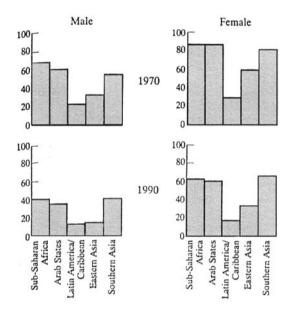
- Invariably women represent the largest share of the illiterate population and will continue to do so. As shown in Table 2, in 1990 for the developing countries taken as a whole, the female illiteracy rate is 45 percent compared with 25.1 percent for males. The disparities vary however, between the different groups of countries.


Figure 2. Developing countries' illiteracy rates by sex (%).

Oceania	11.6	9.6	7.5	5.5	11.2	8.2	6.1	4.0	12.0	11.0	8.9	7.0

- The smallest disparity occurs in Latin America and the Caribbean where the rate for females is gradually catching up with that for males.
- Although the illiteracy rates in Eastern Asia are generally smaller than in the other regions the disparity between the sexes is higher than in any other region apart from Latin America and the Caribbean: the rate for females (33.6 percent) is more than twice that for males (14.3 percent).
- In Sub-Saharan Africa, the Arab States and Southern Asia the female illiteracy rates are presently above 60 percent while the rate for males varies between 35 percent and 41 percent. If current trends continue, in 2000 one female adult out of two will still be illiterate in these three regions. In Southern Asia the projected female illiteracy rate for 2000 will still be higher than that observed for males 30 years earlier in 1970.

4. Illiteracy by Age

The amount of illiteracy varies a great deal between the different generations. Table 3 attempts to illustrate this phenomenon by presenting illiteracy rates by age group in developing countries. The base data have been divided into four age groups of different sizes: 15 to 19 years, 20 to 24 years, 25 to 44 years, 45 years and over.

- Of course the older generations have the highest illiteracy rates as they have not profited from the possibilities of schooling given only recently to the younger generations. Unless present trends are altered by an intensive effort to educate adults, the illiteracy rate of persons aged 45 and over risks to stay at a high level until 2000, particularly in Sub-Saharan Africa, the Arab States and Southern Asia: women in this age group will be particularly affected by this situation with an illiteracy rate of around 80 percent in 2000.
- There have been important reductions (in some cases substantial) in the illiteracy rates for the age groups 15–19 years and 20–24 years over the last 20 years and this should continue until 2000. This is the result of the great efforts made since 1960 in most of the developing countries to enroll children in primary school.
- Figure 3 clearly shows both the expected decrease in the illiteracy rates for the youngsters aged 15–19 years and the decrease in the

Table 3. Adult illiteracy rates by age group in developing countries (percent).

	Age group	Total			Male			Female

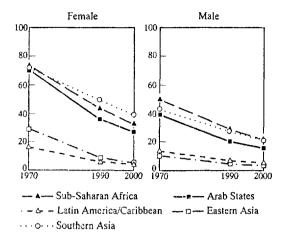
	45 +	37.3	27.5	21.4	31.0	23.1	18.2	43.3	31.5	24.3
Eastern Asia	15–19	19.5	6.3	3.6	10.3	4.0	2.5	29.2	8.8	4.8
	20–24	25.5	8.5	4.7	14.0	5.3	3.1	37.9	12.2	6.4
	25–44	43.8	16.8	9.8	27.9	9.0	5.5	61.0	25.0	14.2
	45 +	78.0	51.8	36.2	63.5	34.1	20.9	91.6	69.4	51.3
Southern Asia	15–19	56.7	37.7	29.4	42.7	26.8	20.7	72.0	49.5	38.6
	20–24	61.1	42.3	33.4	46.7	30.4	23.7	76.2	55.3	44.0
	25–44	69.2	53.1	44.1	55.4	39.7	32.0	83.9	67.7	57.2
	45 +	79.1	71.1	64.7	67.0	57.0	50.0	92.4	85.5	79.7


Figure 3. Illiteracy rates in the age group 15 to 19 years in the developing countries (%).

- The female illiteracy rate for the age group 15–19 years in Eastern Asia (a region which still has large disparities between the sexes in the global rate aged 15+) has rapidly decreased and by 2000 should be at about the same level as Latin America and the Caribbean. As for males, the illiteracy rate for the age group 15–19 years has always been lower in Eastern Asia than in the other regions.
- In some regions (sub-Saharan Africa, Arab States, Southern Asia), the illiteracy rate for the age group 15–19 years projected for 2000 seems to be still very high and disturbing (over 20 percent). There is always the possibility that such trends could be changed following educational plans and policies decided as part of the program concerning education for all.

disparity between the male and the female rates. The decreases are most important in the three regions which had very high illiteracy rates (especially for females) in 1970. For example, the illiteracy rate for females aged 15–19 years in the Arab States decreased by half between 1970 (70.5 percent) and 1990 (36.0 percent) and could decrease even further to 26.6 percent in 2000.

Oracy

A. M. Wilkinson

'Oracy' is a term for talking and listening, by analogy with 'literacy' for reading and writing. It was coined by Wilkinson (1965) in an English and Welsh Schools Council Project at Birmingham University. At that time literacy dominated the school curriculum as a means of learning. A term was needed to give equivalent status to oral/aural activities. Implications of the term were explored in this and a later project (Wilkinson et al. 1974).

Oracy was characterized as 'a condition of learning in all subjects'; as being not merely a skill but the 'essential instrument in the humanizing of the species'; as being a fit subject of educational 'awareness'; as being essentially interrelated with literacy; and as being susceptible of evaluation.

Against the then preoccupation with 'speech training,' it was emphasized that oracy arose in response to the needs of the situation rather than from direct teaching. None of these propositions was part of accepted wisdom in education at that period.

The tenacity of these ideas is indicated by their general currency today in curriculum movements in, for instance, Australia, Canada, and New Zealand, as well as in the UK, where in the early 1990s the National Oracy Project involved over three-quarters of the English and Welsh Local Education Authorities. The continuing influence of the ideas may be seen in the Kingman Report (DES 1988), which focuses on language awareness, and the Cox Report (DES 1989), where evaluation is a central concern,

and which quotes the original research on the need to 'create circumstances to which both speaking and listening are the natural responses.' The UK National Curriculum, compulsory in all state schools, prescribes speaking and listening as one of the three Profile Components in English.

The original research team perceived oracy as having more than linguistic implications. The Crowther Report (HMSO 1959) has set out 'numeracy' and 'literacy' as marks of the educated person. With graceful self-restraint the team described this focus as 'academic.' Numeracy, literacy, *and* oracy they argued were the modern equivalent of the nineteenth century's 'three Rs,' that is, basic educational requirements. Thirty years later these three concepts were described by the English and Welsh National Curriculum Council as 'forming the basis of a proper and liberal education to the highest standards parents expect.'

The term was first published in Wilkinson (1965); key passages are reprinted in Wilkinson et al. (1990), which presents aspects of recent thinking on the topic, as does MacLure et al. (1988).

Pidgins, Creoles, and Minority Dialects in Education
J. Siegel

Pidgins, creoles, and 'nonstandard' or minority dialects (such as African American Vernacular English (AAVE) or Ebonics) are generally stigmatized in formal education. While they may be used informally in the classroom, they generally have no official role and are seen as something to avoid in order to learn the standard language of education.

1. Reasons for Lack of Official Use

The main reason for pidgins, creoles, and minority dialects not being used in formal education is that most people, including educators, still believe that these language varieties are deviant forms of the standard to which they are related. Even when these varieties are recognized as legitimate forms of language, some educators, administrators, and linguists still argue that using them in education would be both impractical and detrimental to students. One argument concerns the lack of autonomy and standardization. Especially in situations where there is a continuum of usage from nonstandard to standard, it is difficult to select a norm to be standardized for use in education. Another 'impractical' argument is that even if a pidgin, creole, or minority dialect could be standardized, the cost of developing written materials would be a disadvantage. Thus, some linguists advocate only the oral use of such varieties in the classroom to facilitate communication in the early years, but not the written use.

However, even oral use is discouraged because of various 'detrimental' arguments. The first of these is that since the goal of the education system is the acquisition of the standard language of education, using a stigmatized variety in the classroom is seen as a waste of time—time that would be better spent learning the standard. Closely related is the 'ghettoization' argument which asserts that using a nonstandard variety of speech in the classroom deprives children of the instruction they need to get the economic benefits that speakers of standard varieties have, and condemns them to permanent underclass status. Third is the 'interference' argument which claims that using a pidgin, creole, or minority dialect in education will make it difficult for students to learn the standard because of negative transfer (see *Language Transfer and Substrates*) or confusion between the two closely related varieties.

2. Arguments for Use

Nevertheless, over the years there have been many calls for legitimizing the use of pidgins, creoles, and minority dialects in education. Some arguments have been mainly socio-political, pointing out the relationship between linguistic and political subjugation and emphasizing the rights of the speakers to express

747

their own linguistic identity and to be educated in their own languages. Other arguments for using pidgins, creoles, or minority dialects have been educational, focusing on one or more of the following obstacles faced by students:

    (a) negative attitudes and ignorance of teachers;

    (b) negative attitudes and self-image of the students themselves because of denigration of their speech and culture;

    (c) repression of self-expression because of the need to use an unfamiliar form of language; and

    (d) difficulty in acquiring literacy in a second language or dialect.

In recent years there have been some initiatives to deal with these obstacles. These are of two types: development of resources for teachers, and establishment of educational programs actually using pidgins, creoles, or minority dialects in the classroom.

3. Resources for Teachers

Important references giving background information about creoles have been developed for teachers of Caribbean immigrants in the USA, Canada and the UK. In Australia, public awareness about creoles and minority dialects has been promoted through professional development courses, publications, and information packages aimed at non-linguists, especially teachers and students.

4. Actual Use in Education

There are three types of programs in which pidgins, creoles, and minority dialects are actually used in education: instrumental, accommodation, and awareness. The goals of all three types are usually the same: additive bilingualism or bidialectalism—helping students to acquire the standard language while maintaining their own way of speaking and thus their linguistic self-respect (see *Bilingualism, Societal*). The differences are in the way the students' home varieties are used in the classroom.

In an instrumental program, the home variety is used as the medium of instruction. It is the vehicle for acquiring initial literacy and learning the content of other subjects such as mathematics and health. For primary school children, the standard language is introduced at a later stage, and it eventually becomes the medium of instruction for at least some subjects. National instrumental programs using creoles exist using Seselwa in the Seychelles, Haitian Creole in Haiti, and Papiamento in the Netherlands Antilles. There are also some individual primary programs using Tok Pisin in Papua New Guinea, Kriol and Torres Strait Creole in Australia, Krio in Sierra Leone, Guadaloupean Creole in Guadaloupe, San Andres Creole in Colombia, and nonstandard dialects in Norway and Sweden. In the USA, bilingual programs exist for immigrants speaking Haitian Creole and Capeverdean. Pidgins and creoles are also used in nonformal adult educational programs in Dominica, St. Lucia, Mauritius, Solomon Islands, Vanuatu, and the UK.

In an accommodation program, the home variety is accepted in the classroom, but it is not a medium of instruction or subject of study. In the early years of school, students may use their home varieties of language for speaking and sometimes writing; or teachers may utilize their students' own interactional patterns and stories for teaching the standard. Accommodation programs of this type are reported in the literature for speakers of Hawaii Creole English (HCE) and AAVE. At higher levels, literature and creative writing in a creole may be accommodated into the curriculum, as has been done in Trinidad and Tobago and other parts of the Caribbean.

An awareness program goes a step further by making the students' home language a topic of study. These varieties are put into context by teaching some basic sociolinguistics about language variation, standardization, attitudes, etc. In 'contrastive' awareness programs, the grammatical rules and pragmatics of the pidgin, creole, or minority dialect are explicitly contrasted with those of the standard variety. An additional objective here is separation: helping students acquire the standard by focusing on how its structure and use are different from their own varieties. Awareness programs (or programs with awareness components) have existed for speakers of HCE in Hawaii; for Caribbean Creole English speaking immigrants in the UK, USA, and Canada; for speakers of nonstandard dialects in the Netherlands; for speakers of Aboriginal English and Kriol in Australia; and for speakers of AAVE in the USA. The program proposed by the Oakland School Board that sparked off the Ebonics debate in the 1997–98 was actually an awareness program (see *Ebonics and African American Vernacular English*).

5. Research

Research on instrumental programs in Australia and the Seychelles has shown that students educated bilingually in their creole mother tongue and the standard outperformed students educated in only the standard language—not only in general subjects such as mathematics but also in the standard language itself. Studies in Papua New Guinea, the Caribbean, and Scandinavia have shown that learning literacy in a pidgin, creole, or nonstandard dialect leads to increased reading proficiency in the standard dialect, thus refuting the interference argument. However, with regard to AAVE, opinion is divided about the effectiveness of using 'dialect readers' in teaching reading. Some linguists believe that differences between AAVE and the written standard may not be sufficient to cause problems with reading

748

acquisition if children are allowed to read as they speak.

Research into accommodation programs in Hawaii has shown increased reading achievement and development of spoken standard English as a result of classroom use of patterns of interaction found in HCE. With regard to AAVE, a few studies of the effects of accommodation in the classroom demonstrate greater self-esteem among students, increased participation, higher reading scores, and more use of standard English.

Students who went through programs with awareness components in Hawaii showed improvements in tests of standard English use and oral language skills. Awareness programs in The Netherlands increased the rate of participation of dialect-speaking children as well as the mean length of their utterances. One awareness program for Caribbean English Creole speaking high school students in the USA led to much improved academic performance for most of the participants. Several awareness programs for AAVE-speaking students using contrastive analysis have been beneficial in terms of reduced dropout rates and significant improvements in performance in standard English.

6. Accounting for the Research Results

In summary, the studies and reports evaluating programs of all three types describe various positive results from using pidgins, creoles, and minority dialects in education. There seem to be several obvious reasons for these results. First, for the instrumental programs, students find it easier to acquire literacy skills in a familiar variety of language and then transfer these skills to the standard. Second, in all three types of programs, students can express themselves better in a familiar language (without fear of correction) leading to better cognitive development. Third, teachers have more positive attitudes because of the nature of the programs, which make them aware of the legitimacy and complex rule-governed nature of their students' languages; therefore, they have higher expectations. Fourth, students have more positive attitudes towards their language and themselves, leading to greater interest and increased motivation.

Another reason, however, may be related to aspects of psycholinguistics and second language acquisition. Students who speak a pidgin, creole, or minority dialect often have trouble separating it from the standard variety to which it is related. Because of the many similarities between the home and school varieties, students are often not aware of the differences. But when students look at features of their own varieties in the classroom, they have a greater chance of noticing features of the standard, which are different. This helps them to build the separate mental representation of the standard, which is necessary for language acquisition.

Spoken Language in the Classroom
N. Mercer

The term 'classroom language' is usually taken to mean the language used by teachers and children doing educational activities in schools. It is rarely used with reference to adult education. It is also more usually used to refer to the spoken language of the classroom rather than to what is read or written (though of course written language has a very significant role in school education), and so it is spoken language which is considered here (see *Oracy*).

1. Functions of Spoken Language in the Classroom

Starting with the language of the teacher, its most obvious function is to inform or instruct. Teachers may tell children what they are to do, how they are to do it, when to start, and when to stop. They also

749

assess children's learning through talk, and use talk as a way of providing children with certain kinds of educational experiences which would be hard to provide by any other means (e.g., telling stories, reading poetry, describing objects). One very important function of talk for teachers is to control the behavior of children; indeed, with the demise of corporal punishment in many countries, talk is the main tool of control in the classroom.

Schoolchildren might be expected to use talk primarily to request information and guidance from teachers. However, observational research in classrooms has shown that, as they progress though their school careers, the frequency at which children make spontaneous requests for information from teachers decreases. In secondary schools, most of children's talk in class is in the form of responses to teachers' questions, while requests for information they lack are more often covertly addressed to their peers (see *Observing and Analyzing Classroom Talk*).

In schools in many parts of the English-speaking world (notably the UK and Australia), teaching methods have increasingly come to favor the organization of children into pairs and groups for some learning activities, and this may increase the proportion of both 'on-task' and 'off-task' talk between children. The level of talk in a classroom is, of course, a contentious educational issue. Traditional educational values associate a low level of talk with effective classroom control (success at 'keeping 'em quiet' is a traditional measure of a teacher's effectiveness), but modern methods often place strong emphasis on activities which encourage children to share knowledge with their peers and to develop their oral communication skills (see *School Language Policies*).

The functions of 'off-task' talk have been given little attention by researchers, but for children such talk may on some occasions in school represent the most significant communications which take place. Talk between children working together which seems superficially off-task may be important for developing the working relationship of a pair or group. And, less welcome from a teacher's point of view, children can effectively employ off-task talk to subvert the official social order.

A more general and important function of talk in the classroom, whether between a teacher and one or more pupils or between pupils working together, is as a means for developing shared understanding. Through joint action and talk, participants in the process of teaching and learning build a body of common knowledge which provides a contextual basis for further educational activity. The extent to which educational knowledge is made common through classroom discourse is one measure of the effectiveness of the educational process.

2. The Structure of Classroom Language

The spoken language of the classroom has some interesting and distinctive discourse features (see *Discourse*). (They can be called 'discourse features' because they are aspects of the continuous linguistic text created by the interchanges between teachers and pupils, rather than of discrete utterances.) Consider, for example, the following piece of classroom talk (1):

Teacher: Where is Argentina?   (1)
Pupil: In America.
Teacher: Well, yes, in South America.

What happens here is that the teacher 'initiates' an exchange with a pupil the pupil 'responds' and the teacher then provides 'evaluative feedback' on that response. This three-part sequence of 'Initiation–Response–Feedback' (usually summarized by researchers as IRF or IRE) can be described as a minimal episode of teaching-and-learning. It is the frequency of such sequences (called 'exchanges' in the terminology of discourse analysis—see Sect. 2.1) which gives classroom talk its distinctive structure.

2.1 Analysis of Classroom Discourse

The structural analysis of talk can be extended to include larger and smaller units than exchanges. Sinclair and Coulthard (1975) were the first to offer a hierarchical scheme for analyzing classroom talk, shown diagrammatically in Fig. 1. A lesson is first divided into a series of topically coherent units, called 'transactions.' These are then further broken down into 'exchanges,' which in turn can be subdivided into 'moves.' Thus the teaching exchange described consists of three moves, an 'Initiation' (I), a 'Response' (R), and an 'Evaluation' or 'Feedback' (F). Finally, moves are themselves broken down into basic functional units called 'acts.'

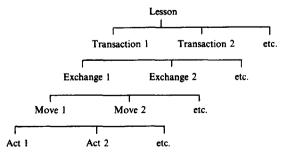
Sinclair and Coulthard identified four main types of exchanges initiated by teachers: 'directives,' 'checks,' 'informatives,' and 'elicitations.' They also identified 22 acts, which they claimed were sufficient to describe all classroom discourse. The following is


Figure 1. The hierarchical organization of classroom talk (from Sinclair and Coulthard 1975).

an example of a transaction analyzed into exchanges and moves:

		Moves	Exchanges (2)
Teacher:	What do you notice there— what's special about that particular section of tape— what's that child doing— Anybody	I	elicitation 1
Pupil:	Trying to say something	R	
Teacher:	Er, right Rosita—what's he actually trying to say	F I	
Pupil:	Trying to get a word out of his mouth	R	elicitation 2
Teacher:	And what's the word he's trying to get out	(F)I	elicitation 3
Pupil:	Mm daddy	R	

(adapted from Graddol et al. 1987: 197)

The first of the three exchanges above begins with the teacher producing a string of acts which make up one move (an initiation). The second exchange can be considered to have no feedback move, or the initiation for the third exchange can be considered to be functioning simultaneously as feedback (indicated by the coding (F)I).

One valuable application of this kind of analysis of classroom talk is to indicate ways in which teachers control the agenda of lessons through discourse. It also shows how being a *pupil* requires children to talk in certain ways which are complementary to those of the teacher. Research suggests that, on entry to school, most children very quickly learn to take on this aspect of the pupil role (see *Home Language and School Language*). Some educationalists see such rapid adaptation to the rules of classroom discourse as a necessary and valuable beginning to children's academic career, while others believe that it demonstrates how schools impose unnecessarily rigid constraints on young children's opportunities for talk and learning (e.g, Willes 1983).

3. Teacher-talk

Observational research in the USA (Flanders 1970) revealed a characteristic of classroom talk which subsequently proved to be a common feature across a wide range of teachers, classrooms, and even countries. It is known as the 'two-thirds rule,' because it has been observed that:

(a) for about two-thirds of the time someone is talking;
(b) about two-thirds of this talk is the teacher's;
(c) about two-thirds of the teacher's talk consists of lecturing or asking questions.

Some teachers and educational theorists have used this discovery as an indictment of teachers' excessive dominance over classroom life and children's opportunities for self-expression and exploration through talk: but such judgments can only safely be made if based on a proper understanding of what teachers are trying to achieve through talking to children in class (cf. Mercer 1995: chap. 3, Wood 1992).

3.1 Teachers' Questions

Teachers are sometimes not only accused of asking too many questions, they are also seen as behaving oddly because it is clear that for the great majority of questions they ask they already know the answers. This seems, on first consideration, to be a rather peculiar kind of language behavior. (There are even jokes about it: *Teacher*: 'How many millimeters in a centimeter?' *Pupil*: 'If you don't know you should be in a different job!') But asking questions of this kind only seems odd if teachers' behavior is judged against some general and abstract standard of language use, whereby the only acceptable function of a question is to provide information requested by the ignorant enquirer. Such standards cannot be appropriately applied, because—as with all situational varieties of language—the nature and function of teacher-talk needs to be considered in context. To understand teachers' unusual use of questions, one needs to know why they ask them.

In order to plan and evaluate their teaching and to assess the learning of their pupils, teachers need constantly to monitor children's knowledge and understanding. Most of the questions they ask are meant to serve this purpose, and on the whole probably do so quite effectively. Teachers and pupils are usually perfectly familiar with this convention (the humor of the joke above depends on the hearer being so), and so few misunderstandings are likely to arise about why they are being asked. However, misunderstandings do sometimes arise because teachers may not choose to ask the most direct, explicit questions. They may want to avoid *putting words into children's mouths* because that would not test children's real understanding, or they may feel that children should be required to put some *mental effort* into making connections between the work they have done and what they are being asked. Consider the following sequence from a science lesson in a UK secondary school classroom, in which the pupils have been doing a series of practical activities about air pressure (3):

Teacher:	Well we blew into it and what happened?	(3)
Pupil F:	All the water came out of the straw.	
Pupil P:	The water came out of the s—top.	
Teacher:	All came out! Now why? Come on! This one's easy.	
Pupil F:	'Cos when you were blowing bubbles in, all the...air came up the straw...and the water with it.	
Teacher:	Ooh no! I don't think that's quite right. When we blew air through here...where did it go?	

Pupils (*together*):	Into the bottle.
Teacher:	Into the bottle! So was there more air in here or less air?
Pupils (*together*):	More.
Teacher:	More air, wasn't there? There was a lot more air in here. Now this air...wanted to do what?
Pupils (*clash of voices*):	Get out. Push water...push water outside to get room for itself.
Teacher:	Yes, ah. That's a very good answer.

(Barnes 1976: 73–4)

In this extract the teacher uses questions in a kind of guessing game to draw out from the children some key ideas of the lesson. The questions thus are not merely assessment, but are part of the teaching.

3.2 Teachers' Control over Knowledge Content

Teachers use talk not only to control children's behavior and to monitor their understanding, but also to guide children's learning. Through talk, teachers mark some knowledge and experience as significant. They also attempt to create continuities between past, present, and future events in children's classroom experience. Knowledge and experience which is not considered educationally significant or valuable by a teacher will normally be marked as such in their talk, either by simply ignoring it or by dismissing it more explicitly.

One of the most obvious ways in which teachers mark knowledge as significant or otherwise is in their evaluative feedback to children's responses to questions in the IRF exchanges described above. For example, *wrong* answers to a teacher's question are commonly followed by one of the following events: (a) the teacher says the answer is wrong, or (b) the teacher ignores the wrong answer. The teacher is likely then to ask the question again, either in the same words or in a paraphrased form.

Teachers also mark the significance of elements of knowledge and experience in other, more subtle ways. Three features of teachers' discourse which illustrate this are 'cued elicitations,' 'joint knowledge markers,' and 'reconstructive recaps.'

3.2.1 Cued Elicitations

These are IRF exchanges in which the teacher asks questions while simultaneously providing heavy clues to the information required. Cued elicitation may be achieved merely by the wording of the question, but it is often accomplished by some other communicative means such as intonation, pausing, gestures, or physical demonstrations. The extract below, from a primary school lesson, provides a good example of this (nonverbal features of the discourse are shown in italics, and emphatic speech is in bold type). The teacher is talking to the children about Galileo's studies of pendulums:

Teacher:	Now he didn't have a watch but he **had** on **him** something that was a very good timekeeper that he could use to hand straight away	(4)
		Teacher snaps fingers on 'straight away,' and looks directly at pupils as if inviting a response.
	You've got it. I've got it. What is it? What could we use to count beats? What have **you** got?	*Teacher points on 'You've' and 'I've,' then beats her hand slowly on the table, looking around at the pupils who smile and shrug.*
	You can feel it **here**	*She put her fingers on her wrist pulse.*
Pupils:	Pulse	*Speaking in near unison.*
Teacher:	A pulse. Everybody see if you can find it.	*All copy the teacher, feeling for wrist pulses.*

(adapted from Edwards and Mercer 1989: 142)

3.2.2 Joint Knowledge Markers

These are statements in which a teacher indicates that some shared experience is important and, often, that it is particularly relevant to the present task. One common way of doing so is to use *we* in recalling an event, as in 'Last week, we saw that French nouns can be either masculine or feminine. So what I want you to do now is....' Another way is to point out emphatically to the class that one of them has given a 'very good answer' to a question.

3.2.3 Reconstructive Recaps

These are accounts by teachers of past activities or events shared with the children, in which what went on is selectively reported to highlight aspects seen by the teacher as being educationally significant (and, concomitantly, to play down aspects seen as irrelevant or confusing). For example, in summarizing discussions in class, teachers typically leave out all the 'red herrings' which were raised. To give a more extreme, but real, example: although a series of mishaps had thwarted all but one of many attempts to create a vacuum in a bell-jar, the teacher of the secondary class involved subsequently referred to this occasion as simply 'the lesson in which you made a vacuum.'

4. Technical Language in the Classroom

One of the aims of education is to give children access to important parts of the cultural heritage of their society. A further aim is to enable them to become active participants in the continuing development of that cultural heritage. The pursuit of both of these

752

aims entails children becoming familiar with the technical language of the subjects they study. Used effectively, the technical vocabularies of science, mathematics, art, or any other subject provide clear and economical ways of describing and discussing complex and abstract issues. A shared understanding of musical terminology, for instance—terms like *octave, bar, key*, and so on—makes it possible for two people to discuss, in the abstract, phenomena which otherwise would have to be concretely demonstrated. The discourse of educated people talking about their specialism is explicit only to the initiated. Becoming familiar with the language of a subject is thus an important requirement for entering the intellectual community of scientists, mathematicians, artists, or whatever.

Some technical words which are used rarely in the wider world may be familiar and well-understood by young children because they represent concepts commonly and easily demonstrated in the classroom. (A good example is 'alliteration.') However, the use of technical language in the classroom often causes much confusion and misunderstanding. One reason is that classroom discussions may leave children unsure about what words really mean: teachers may often assume that the meaning of a word is obvious, while children are reluctant to ask questions which reveal their ignorance. Moreover, even the best teacher will find it hard to relate the meaning of some terms to children's concrete experience (concepts like *atomic weight* and *feudalism* can only be read about or discussed, not demonstrated, in class). A consequence may be that many technical words become for children mere jargon, and as such represent an obstacle to their developing understanding. (Educational research has provided many bizarre and salutory examples of how technical terms may be misunderstood, and most teachers will have their own collections. Two such examples are of a twelve-year old who thought that *quandary* meant a four-sided figure, and a school leaver who, after professing no knowledge of *subtractions*, demonstrated that he could nevertheless do *take-aways*.)

5. Conclusion

The analysis of the spoken language of classrooms has made a practical contribution to education by clarifying some of the ways that teachers and children use talk in the pursuit of learning. With a clearer picture of what is said and done, it is more possible to evaluate the processes of teaching and learning in school, and so perhaps plan for more effective communication in the schools of the future. By identifying some typical and distinctive features of language use in one kind of social setting (the classroom), the research which provided this analysis has also made a very significant contribution to the study of language in society, and to language as text, in general.

Standard English and Educational Policy

M. Farr and A. Ball

The term 'standard English' generally refers to the variety of English used by the formally-educated people who are socially, economically, and politically dominant in English-speaking countries. Although the term is widely used, it is difficult to define precisely because of the variation that exists within what is considered 'standard,' even within one country. Standard English is that variant which is generally taught in schools and is regarded as the 'prestigious' dialect in many English-speaking societies. Non-standard English, in contrast, is spoken by groups of people who have been isolated from the

753

standard dialect, who have not had the opportunity to acquire the dialect of the social elites, or who see value in preserving their own group dialect. The term non-standard English refers to any variety of English which does not conform in pronunciation, grammatical structure, idiomatic usage, or choice of words to the variety that is generally characteristic of formally educated native speakers of English. A distinction can be made between oral and written standard English, the latter varying less within countries, yet still varying somewhat from one English-speaking country to another. We can see that as the English language spreads to different societies in its oral form, it changes through contact with different cultures, so that there are different Englishes (see *New Englishes*) in different parts of the world (e.g., Indian English, Singapore English, Scots English, etc.). Written varieties of English, in contrast, tend to be more standardized, although even these vary from region to region. Even without a fully specified definition of standard English, however, a primary characteristic of any written standard English is the absence of socially stigmatized features (e.g., multiple negation) which are associated with nonstandard English dialects.

1. Standard English in Multicultural Contexts

Demographic changes worldwide have illuminated the multicultural nature of many English-speaking societies. Although the recognition of this multiculturalism has become particularly salient in recent decades, the reality of such pluralism no doubt has existed throughout human history. The identification of individuals with particular population groups (e.g., those based on socioeconomic class, gender, age, ethnic origin, or region of a country) is reflected in their use of particular linguistic items (e.g., a particular pronunciation or lexical item) in their speech and, sometimes, in their writing. Such variation, of course, has significant implications for educational policy (Farr and Daniels 1986).

A few definitions will illuminate the following discussion. The term 'mainstream' is used to refer to those people in societies around the world who are characterized as literate, school-oriented, aspiring to upward social mobility through success in formal institutions, and looking beyond the primary networks of family and community for behavioral models and value orientations (Heath 1983). In English-speaking countries, these are the people who are associated with 'standard' English. 'Non-mainstream,' then, refers to those groups which do not conform to the above characteristics, and whose members speak dialects or non-prestige varieties of English that are considered 'nonstandard.' A dialect (see *Dialect and Dialectology*) is either a regional or a social variety of a language; it is distinguished by specific phonological, syntactic, semantic, and prag-

matic features. The latter area, pragmatics, involves the culturally embedded uses of language that characterize a particular group, whether that group is mainstream or nonmainstream. Culture is defined here primarily as a system of knowledge shared by a group of people which both gives rise to behavior and is used to interpret experience. Thus both dialect and culture involve cognition, i.e., both linguistic and cultural competence, or what Hymes (1974) has termed 'communicative competence.'

2. Differences in Communicative Competence

All normal human beings, having been enculturated into one group or another, have communicative competence, i.e., the knowledge to speak the language of their group in ways considered appropriate to that group. Communicative competence, however, can differ from group to group, and problems may arise in intergroup communication (Gumperz 1982, Kochman 1981, Tannen 1986). School, of course, is a primary institutional setting for such intergroup communication. Even if students in a particular school are primarily from one population group, schooling itself, in Western English-speaking societies, is part of mainstream culture, and the communicative competence expected in schools closely resembles that of mainstream, middle class groups. Students from nonmainstream groups enter school with a set of linguistic and cultural resources which may differ from—even conflict with—those of the mainstream school culture (Farr 1993). It is important to understand that such differences in communicative competence are simply differences, not deficits in either a linguistic or cognitive sense, since teacher expectations and attitudes can influence significantly the achievement of their students (see *Educational Failure*).

A substantial body of sociolinguistic research has documented the linguistic characteristics (phonological, syntactic, and semantic) of a variety of nonmainstream English dialects in the USA, UK, and Australia (Farr 1986). A primary finding of all this work is that such dialects are as complex and as regularly patterned as other varieties of English, which are considered more standard. That is, contrary to the common belief among many mainstream groups, speakers of nonstandard dialects do not thereby have linguistic deficits; rather, they often have linguistic rules in their grammars which simply differ from those of standard Englishes.

Other sociolinguistic research has described the culturally embedded aspects of language use, rather than grammatical characteristics, among nonmainstream groups. Such studies, carried out within Hymes's framework for the ethnography of communication, have focused primarily on the contrast between language use at school and in home/community contexts (see *Home Language and School*

Language). These studies have noted that norms for language use, quite apart from the linguistic characteristics of the dialects involved, can differ considerably from one cultural group to another. For example, silence may be considered appropriate in certain contexts for one group, while speaking is the norm in those contexts for another group. Moreover, norms for particular styles of speaking, e.g., with differing levels of directness or indirectness (often indicating degrees of politeness), can vary dramatically from group to group, even when those concerned are speaking the 'same' language (see *Politeness*). In addition, research on the uses of written language among various groups has shown that different cognitive styles underlie different uses of literacy. Thus there is considerable opportunity for miscommunication between speakers (and readers and writers) from different groups, based on differences in language structure, language use, and literary practices.

Schools, of course, as well as other formal institutional settings in modern societies, are a focal point for such cross-cultural communication, especially with regard to the use of literacy. The standard written language, whether in textbooks or on institutional forms (e.g., from banks or government agencies), often reflects the ways of speaking, writing, and thinking of the dominant institutions and groups of the society. Regarding the learning of literacy, many students from nonmainstream cultural groups are faced with a conflict between their own cultural and linguistic systems (and their identity as members of their 'home' groups) and those of the standard written language. The difficulties inherent in resolving such conflicts provide one explanation for low literacy levels among these populations (see *Educational Failure*). Other explanations trace the low literacy levels to lack of access to instruction which emphasizes 'higher order' thinking processes, as opposed to 'lower order' literacy skills. The focus of instruction, either on critical 'literate' thinking or on alphabetic skills, is, of course, guided by attitudes toward and expectations for students on the part of educators and policy makers.

3. Educational Policy

Recognizing the differences that exist between the sociolinguistic resources of students from nonmainstream groups and those that currently are needed for success in formal schooling leads to the need for educational policy regarding what kind of oral and written language should be taught to multicultural student populations (see *School Language Policies*). Three positions can be assumed in this situation: eradication, biloquialism, and appreciation of dialect differences (Fasold and Shuy 1970).

Eradication, the traditional policy in the English teaching profession, assumes the undesirability of language patterns associated with nonmainstream groups and attempts to replace these patterns with more desirable mainstream ones. This, in fact, describes the current, although tacit, policy in most schools, a policy which, many would argue, has not succeeded.

Biloquialism, often termed bidialectalism or biculturalism (as parallels to bilingualism or multilingualism), encourages the learning of mainstream language patterns without eliminating or denigrating nonmainstream ones. The goal of this kind of instruction is to enable students to switch from one linguistic style (or dialect or language) to another according to norms of appropriateness to the context in which the language is used. Since all speakers shift among more or less formal styles depending on context, this position is a natural one, and has, moreover, the advantage of providing a compromise position between the other two.

Appreciation of dialect differences is the logical opposite of eradication. This position maintains that, since research clearly has shown all dialects to be linguistic and cognitive equals, it is unjust to insist on replacing nonstandard dialects with standard ones. Moreover, many have argued (Sledd 1988) that the time and effort spent on eradication (with remarkably unsuccessful results) would be better spent enlightening mainstream groups about the naturalness of variation in language and eliminating prejudices against nonmainstream groups.

Although each of these positions has its advocates, the most pragmatic position seems to be that of biloquialism, which advocates the teaching of mainstream patterns as an expansion of students' linguistic repertoires, not as a replacement for their original ways of speaking. Since bilingualism and bidialectalism exist in societies around the world, such a policy clearly seems to be natural and attainable. Why, then, have nonmainstream students in English-speaking countries not become biloquial in the natural course of events? Research (Ogbu 1990) has shown that some nonmainstream groups maintain their indigenous language patterns as symbols supporting an oppositional identity which resists the mainstream forces which denigrate their vernacular culture. This argument, however, lacks explanatory power for those vernacular speaking minorities in modern urban industrial societies with strong, supportive, and collective ethnic identities who excel academically and who have no difficulty crossing cultural/language boundaries. Other research (Erickson 1984) locates the problem in the micropolitical communicative processes between individuals from different groups. The implication here is that the micropolitical processes reflect more macro ones from the larger society; sociolinguistic differences can either be used to escalate conflict between differing individuals or be put aside in the

effort to communicate. For biloquialism to be an effective policy, then, it will have to be supported by a larger social context which respects rather than denigrates linguistic and cultural differences. Changing the *status quo* to one of tolerance toward such differences requires social change beyond the scope of language arts teaching, but education can contribute to such social change by teaching both teachers and students that such differences are not deficits. Rather than using differences as resources for conflict, they can be used as a basis for improving instruction in standard language and literacy to multicultural student populations.

4. Instructional Approaches

Ethnographic studies of community uses of language and literacy have been used to improve instruction in two ways: by modifying instruction to be congruent with local ways of using language, and by involving students themselves in doing, and writing up the results of, ethnographic research in their own communities (Au 1980, Au and Jordon 1981, Heath 1983, Moll and Diaz 1987).

Classroom studies have provided an understanding of principles underlying effective language arts instruction to nonmainstream students (Ball et al. 1997, Heath and Branscombe 1985, Lee 1993, Staton et al. 1988). The most important principle of effective instruction for such students is ethnosensitivity, rather than ethnocentrism, on the part of teachers and educational administrators. That is, because communication between student and teacher is central to learning, it is crucial for educators to understand the extent to which they are interpreting nonmainstream students' behavior according to their own cultural and linguistic patterns, which they see as more 'natural' and 'logical' than those that are alien to them.

A second principle involves providing all current and future teachers with information that presents the results of sociolinguistic research on the differences in communicative competence among culturally and linguistically diverse groups in order to explode the myths of cultural and linguistic deficits and to provide a clearer understanding of the resources that diverse students bring into the classroom.

A third principle involves structuring instructional activities that comprise functional and interactive communication; language that is intended as authentic communication, rather than as an artificial exercise, is more likely to call forth the full range of students' linguistic capabilities and to stimulate them to acquire new ones.

A fourth principle concerns the provision of abundant experience with and exposure to standard oral and written English. Such experience provides multiple examples of the linguistic patterns and the cultural assumptions of academic culture; it also provides opportunities for learning other ways of reasoning, those presumed to be necessary not only for schooling, but also for participating fully in modern societies.

Teaching Endangered Languages

L. Hinton

There are presently more than 6000 languages in the world, but almost half of the human population are native speakers of the top 10 of these languages (Grimes 1996). What this means is that the majority of human languages are spoken by very small numbers of people. We are in the midst of worldwide social change where economic and political forces combined with a revolution in communications are working against the continued existence of these small languages. Language shift (see *Language Maintenance, Shift, and Death*) to the world languages is so rapid and so extensive that we can well expect that over half of the languages on earth will disappear in the coming century (Krauss 1992). We call these languages 'endangered,' especially, as is the case with so many now, they are no longer being learnt at home by children, but are known only to adults or even just to a few elderly speakers.

The decline of linguistic diversity in the world is linked to the world political economy which invades and takes over the territories of indigenous peoples, threatens the ecosystems in which they live, and wipes out their traditional means of livelihood. Because of these links, the right to maintain minority languages has become a human rights issue, supported by such international organizations as UNESCO. A worldwide movement for the rights of indigenous peoples is resulting in the development of language revitalization efforts in thousands of speech communities. The revitalization of Hebrew, which had not been spoken as a native language for 2000 years, was an exceptional early case of the revival of an actually extinct language. A more typical case, however, involves revitalization of a language that still has some (perhaps only a few) speakers. Current strong revitalization programs are underway in such locations as New Zealand (Maori), Hawaii (Hawaiian), Spain (Catalan), Wales (Welsh), and Ireland (Gaelic). The multitude of indigenous languages of the Americas are especially threatened, and in recent years literally hundreds of maintenance and revitalization programs have developed all over the hemisphere.

1. The Role of Schools in Language Revitalization

The core of a language revitalization movement necessarily involves second language teaching, since by definition endangered languages are not spoken by a large portion of the population to which that language belongs. Most revitalization efforts are centered in schools. This has an ironic twist to it, because schools themselves have been one of the parties most responsible for language decline. In North America, for example, the first half of the twentieth century saw a purposeful policy of language eradication toward indigenous peoples through the establishment of boarding schools where children were removed from their families and cultures, and punished whenever they were 'caught' speaking their language anywhere on the school grounds. Even when schools do not purposefully set out to destroy languages, their influence on language development and social development is so strong that the children of minority groups may abandon their language of heritage early in life. The end result is that in one generation or another the language ceases to be spoken at home, at which point it becomes moribund.

757

Despite the fact that schools have played such a major role in language shift, they are also capable of being the major players in reversing language shift. When the families find their ancestral language silenced at home, their only hope for reversing language shift is in second language learning, and communities look to schools as the place where second language learning can most effectively take place.

2. Differences Between Teaching Endangered Languages and World Languages

The teaching of endangered languages is very different from the teaching of world languages, in terms of the following factors:

2.1 Resources Available for Language Teaching

Resources may be slim for teaching an endangered language. Funding is rarely stable, pedagogical materials may be nonexistent (at least initially), and finding teachers who are also speakers may be difficult or impossible. Expertise may be lacking in state-of-the-art language teaching methods. Thus, any language revitalization program must have a strong training program and must spend a good deal of energy on the development of materials and curriculum, or else on developing a teaching methodology that is not strongly dependent on materials and fixed curriculum.

2.2 Goals

In a typical foreign language classroom, goals are usually simply to learn the language in order to communicate with native speakers of the language or read literature in that language. For an endangered language, the goals are much larger and the stakes much higher. The language has ceased being the language of communication, so not only must people learn to speak it, but communicative functions of the language must be recreated in order for it to be used again. If the classroom is the site of learning, for a language to be revitalized it must also leave the classroom, and be brought back as the language of communication within the community. The goal, then, is Reversing Language Shift (RLS), as termed by Fishman (1991) (see *Reversing Language Shift*). Furthermore, language revitalization must be seen only as part of a more general cultural revitalization, usually accompanied by the reaffirmation of traditional activities and values and possibly efforts toward ecological restoration as well. All of this means that any language program in the school must be part of a community-wide program, and cannot simply be something the school itself designs and implements without strong community involvement. In fact, very frequently revitalization programs involve the setting up of separate schools, rather than the establishment of a program within an existing school.

2.3 The Consequences of Language Teaching

In the case of successful RLS, the second language learners of today will become the main carriers and teachers of the language tomorrow. This means that any incomplete learning (accent, grammatical, or lexical deficiencies, etc.) will become part of the future of the language itself.

The only way for a learner to become fluent is to create an intensive immersion program. In schools, this generally means a program where the language becomes the language of instruction in the school. Endangered languages, which are not presently used as the language of communication, lack much of the vocabulary needed to talk in today's world and today's classroom. Generally connected with intensive second language teaching for endangered languages must be a way to generate new vocabulary, and some authority structure to oversee the development.

All in all, then, one of the consequences of teaching an endangered language is that the language will undergo intensive change.

The social and political changes that accompany RLS are also often very profound, both in the speech community and in the surrounding 'mainstream' community, as we will see in the Hawaiian example below.

3. Hawaii

One of the most successful programs so far in achieving RLS through second language teaching is the Hawaiian program, run by the 'Aha Punana Leo Foundation. It now has nine preschools and two highschools (one public, one private) with Hawaiian as the main language of instruction, and 14 elementary schools with Hawaiian-language tracks. A recently opened Masters Program in Hawaiian Studies at the University of Hawaii at Hilo means students may go all the way to a master's degree with Hawaiian as the main language of instruction. Children enter preschool knowing English only, but through structured immersion principles, they are usually using Hawaiian exclusively in school within 6 months. Since few people of professional age know Hawaiian fluently, people planning on becoming teachers in the program learn the language at the University of Hawaii. As the 'lead group' of students progressed through school, the University of Hawaii at Hilo kept a year ahead of them in producing materials and books, having to develop the curriculum and write or translate books for all school subjects. This also demanded the development of a massive new vocabulary, so a 'Lexicon Committee' was founded which meets regularly to determine what the new words shall be. For the computer,

important programs such as Claris Works now have a Hawaiian language version. Since people of parenting age do not know Hawaiian, unless they have learnt it in college, parents of the children in the immersion schools are encouraged to do volunteer service in the classroom, and go to once-a-week night classes to learn basic classroom Hawaiian. Parents sending their children to this program often have a strong commitment to the language, and there are a dozen or so families who have committed to making Hawaiian the language of their homes. In order for this program to succeed it needed legislative support, for up to then, it was illegal to use anything but English in the classroom. After a great deal of hard work, Hawaiian and English were made the co-official languages of the state, and it was made legal for schools to teach in either language. Through the enormous efforts of many dedicated and talented people, this program has resulted in the growth of several thousand new fluent speakers.

4. Other Programs

New Zealand served as a model for the Hawaiian program and, like Hawaii, is experiencing a great resurgence of the Maori language. Some other programs around the world, such as Irish, also teach the language in schools nationwide, but do not have such a strong emphasis on immersion and use of the language as the primary language of instruction (although there are enclaves where such schools exist). Smaller groups, such as the Blackfeet and the Mohawk, have developed immersion programs on a smaller scale. Bilingual education has been the focus elsewhere, such as among the Navajo, and the Quechua in the Andes. In some communities, the schools have not been the primary focus of language education. Some of the Pueblos (e.g., Cochiti) have summer immersion programs and after-school classes. In California, where 50 languages are still spoken, but only by a dozen or less elderly speakers each, a unique intertribal program has developed, called the 'Master–Apprentice Language Program,' where adult learners pair up with elderly speakers and are given training that allows them to interact informally together for up to 20 hours per week using only their ancestral language. Some 60 teams, for over 20 languages, have gone through this program over the last 7 years. The goal is for the young apprentice to gain fluency in the language and then to be able to teach children in whatever setting is available (Hinton 1997b).

5. Documentation

An important part of any revitalization program should also be documentation. In their zeal to get new speakers, sometimes communities forget that while the elders are there to help now, they will not be there in the future and they have much knowledge that will probably not be adequately transmitted during their lifetimes. Audiotapes and videotapes of the elders are of tremendous value long after their death, and often form the basis of excellent CDs, storybooks, and other pedagogical materials.

6. Role of the Linguist

In all of these programs, linguists have played a central role in design, development, training, and implementation. The most important functions of the linguist are to bring analytical knowledge of the language into the program where needed, good knowledge of documentation, and effective theory and methodology of language teaching into whatever kind of program is developed. Immersion, communicative competence, and links to cultural revitalization are stressed in all the most successful programs; the role of writing may also be important (e.g., with Hawaiian and Gaelic), or it may be insignificant (as with the California master–apprentice program, where most of the languages have no official writing system or literary tradition, or with the Cochiti, who have officially decided not to write their language at all). Each community has unique needs, and the linguist and the community must work closely together to develop the right program.

SECTION IX

Methods in Sociolinguistics

Attitude Surveys: Question–Answer Process

H. Schuman

The recent development of the interview or questionnaire survey has been due in good part to advances in probability sampling, statistical analysis, and computing. Yet language lies at the heart of all surveys, for fundamentally they consist of questions and answers. Social scientists who carry out surveys recognize that the responses constituting their data are shaped by the form, wording, and context of the questions, and also by the behavior and characteristics of those who do the interviewing.

The main method used to study the effects due to questions or interviewers is the 'split-ballot' experiment. In it, a sample of respondents is divided into two or more parts on a random basis, and then question types or interviewer characteristics are varied across the parts. Sometimes only a single word in one question differs between two halves of a sample; at other times the changes involve complex factorial designs, with both question and interviewer characteristics varied simultaneously. Supplementing the more usual split-ballot or between-subjects experiment are within-subjects and other designs. Thus, although surveys themselves are rightly regarded as nonexperimetal approaches to studying human behavior, most research *on* surveys is experimental. Of course, if probability methods have been used to draw the total survey sample from a larger population (for example, the adult population of the USA), conclusions from the experiment can be generalized to that population on a rigorous basis.

Each type of question variation—wording, form, and context—as well as variations due to interviewers, will be discussed in this article.

1. Wording of Questions

Often what is thought to be the 'same' question can be worded in two or more ways. A classic example was first reported by Rugg (1941) and replicated more than three decades later by Schuman and Presser (1981). In each case, half of a large national sample was asked one version of the question, and half the other version, as shown in Table 1. Although the words 'forbid' and '[not] allow' have different connotations, in this particular pair of questions their practical meaning is identical: to forbid a speech has the same consequence as not allowing it, and vice versa. The experiment shows that a seemingly innocuous change in question wording can have a quite large effect on answers, shifting the percentage willing to restrict 'speeches against democracy' by 21 percent in 1940 and by 26 percent in 1976.

The results in Table 1 illustrate two important points. First, seemingly minor changes in wording can have an importance influence on the distribution of responses to a single question. (Such single-variable distributions are usually referred to in survey research as 'marginals.') Second, each version of the question in Table 1 shows much the same change over time in willingness to tolerate 'speeches against

Table 1. The forbid–allow experiments.*

| | Do you think the United States should forbid public speeches against democracy? | | | Do you think the United States should allow public speeches against democracy? | |
	1940	1976		1940	1976
Yes (forbid)	54%	21%	No (not allow)	75%	48%
No (not forbid)	$\frac{46}{100}$	$\frac{79}{100}$	Yes (allow)	$\frac{25}{100}$	$\frac{52}{100}$
Number of cases	(1300)	(1475)		(1300)	(1375)

*Adapted from Schuman and Presser (1981: 277)

761

democracy' (33 percent for the 'forbid' version and 27 percent for the 'allow' version), and thus the variation in wording does not affect the conclusion about temporal change, provided that wording is held constant when the time points are compared. More generally, it is often (though not always) true, as will be illustrated further below, that effects due to minor variations in wording occur for marginals but not for relationships (e.g., the relation of response to time). This leads survey researchers to treat relationships as more robust than marginals.

The forbid/allow example is one of the largest question wording effects ever discovered. Furthermore, it has been generalized to some other issues besides 'speeches against democracy,' though for reasons not well understood little or no effect occurs on certain issues (e.g., forbidding versus allowing 'cigarette advertisements on television'). Finally, the effect has been reproduced in German, where terms equivalent to 'allow' and 'forbid' are available.

However, the importance of the effect should not be overstated. First, not every type of wording change affects even marginals, and this includes some changes that seem likely to do so. For example, Schuman and Presser (1981) substituted the words 'end pregnancy' for 'abortion' in one experimental manipulation, expecting it to reduce the negative impact of the latter term, yet discovered no glimmer of an effect. Second, in some cases it is difficult to say whether a change in wording is nonsubstantive, as is argued in the forbid/allow case, or substantive in the sense of changing the issue itself. Thus Mueller (1973) suggested, and Schuman and Presser (1981) confirmed, that adding a phrase about preventing a 'Communist take-over' to a question about possible American intervention abroad would increase support in a national sample by about 15 percent. However, it is not clear whether the added phrase serves mainly as rhetoric to rally support emotionally (a nonsubstantive explanation), or mainly as a useful specification that defines the situation more fully (a substantive explanation).

In addition, the type of effect reflected in the forbid/allow experiment is often cited to show the impact of 'small' changes in question wording, but in a sense such a conclusion is circular, since what is large and what is small are not defined independently. The distinction between the articles 'a' and 'the' may seem trivial to some, yet in certain contexts they have profoundly different implications. Introducing an individual as 'the wife' of the ambassador has a different implication than introducing the same individual as 'a wife' of the ambassador.

2. The Form of Questions

The question variations noted so far are limited to particular types of questions. However, it is possible to vary formal features of questions in a way that applies to virtually any inquiry in a survey. Thus, to almost any question, it is possible for a respondent to say 'don't know' in order to indicate lack of relevant attitude or belief. Standard survey questions usually discourage such responses by not offering that alternative explicitly, or even rejecting it when it is given spontaneously and, instead, urging the respondent to think further. Schuman and Presser (1981) carried out a series of split-ballot experiments where one form of the questions (called the 'filtered' form) offered 'don't know' alternatives and the other form did not, though in the latter cases 'don't know' was accepted if given spontaneously by a respondent. Over a large number of experiments, offering a 'don't know' alternative always raised significantly the proportion of people saying 'don't know,' with the mean increase being 22 percent. Particularly striking was the finding that approximately the same increase occurred regardless of the difficulty of the question— the difficulty being measured by the percentage of 'don't know' responses on the unfiltered form.

Other findings from these experiments were also important. Despite the large variation in the proportion choosing the 'don't know' response, the ratio of the other responses to one another (e.g., of 'yes' versus 'no' answers to the question) was seldom affected by the experimental manipulation. Nor was the relation of these other alternatives to different variables (e.g., education) usually affected. Thus, responses to the 'don't know' alternative itself were greatly influenced by the form of the question, but other results involving the question and its relation to other items were not affected. Subsequent research has produced some exceptions to these empirical generalizations, but by and large they remain valid.

Another and more obvious formal feature of questions is whether they are open or closed. Open questions do not present alternatives for respondents, but instead answers are recorded verbatim and then coded (categorized) at a later point, whereas closed questions present two or more alternatives to respondents and ask for a choice among them. Open questions are relatively infrequent in contemporary surveys because they are more time-consuming both to ask and to code, and therefore more expensive to use. They are also usually assumed to be less reliable because of the difficulty of obtaining clear responses and of later coding vague or ambiguous answers. Schuman and his colleagues have carried out a number of experiments comparing open and closed questions, with several fairly clear results.

First, as Table 2a shows, closed questions can constrain responses considerably: answers given spontaneously to an open question about the most important problem facing the USA are mentioned much less often when they are not among the list of alternatives provided to a closed form of the question, even though the latter allows respondents

Table 2a. Offering rare responses.
The open question was 'What do you think is the most important problem facing this country today?'
The closed question was, 'Which of the following do you think is the most important problem facing this country today—the energy shortage, the quality of public schools, legalized abortion, or pollution—or if your prefer, you may name a different problem as most important.'

Category	Response (%)	
	Open question	Closed question
The energy shortage	0.0 ⎫	5.6 ⎫
The quality of public schools	1.2 ⎬ 2.4	32.0 ⎬ 60.0
Legalized abortion	0.0	8.4
Pollution	1.2 ⎭	14.0 ⎭
All other responses	93.0	39.3
Don't know	4.7	0.6
Total	100 ($n = 171$)	100 ($n = 178$)

Table 2b. Omitting possible responses.
The open question was, 'There have been a lot of national and world events and changes over the past 50 years—say from 1930 right up until today. Would you mention one or two such events or changes that seem to you to have been especially important. There aren't any right or wrong answers to the question—just whatever national or world event or change over the past 50 years that comes to mind as important to you.'
The closed question was, 'There have been a lot of national and world events and changes over the past 50 years—say from about 1930 right up until today. Would you choose from the list I read the event or change that seems to you to have been the most important, or if you wish you can name an event or change different from the ones I mention. There aren't any right or wrong answers to the question—just whatever national or world event or change over the past 50 years that seems most important to you. Here is the list: World War II, the exploration of space, the assassination of John F. Kennedy, the invention of the computer, or the Vietnam War?'

Category	Response (%)	
	Open question	Closed question
World War II	14.1 ⎫	22.9 ⎫
Exploration of space	6.9	15.8
Assassination of John F. Kennedy	4.6 ⎬ 37.1	11.6 ⎬ 94.3
Invention of the computer	1.4	29.9
The Vietnam War	10.1 ⎭	14.1 ⎭
All other responses	52.2	5.4
Don't know	10.6	0.3
Total	100 ($n = 347$)	100 ($n = 354$)

Adapted from Schuman and Scott (1987)

to bypass the proffered list and that list is made up entirely of answers rarely mentioned spontaneously.

This finding suggests that only responses given spontaneously to an open question should be considered to represent the 'real' views of respondents. Such a conclusion is too simple, however, as indicated by the data presented in Table 2b. In this case all but one of the responses to a question about the most important events and changes over the past half century were given frequently both spontaneously to an open question and as choices to a parallel closed question. However, the one exception—'the invention of the computer'—was seldom given to the open question but turned out to be the most frequently chosen of all responses to the closed question. What is evidently happening is that 'the invention of the computer' is a possible answer that does not usually occur to respondents, perhaps because it lacks the dramatic character of events like wars and assassinations, yet when offered explicitly it seems appropriate to many respondents as an answer. The two experiments taken together show that there is no straightforward solution to which form of a question, open or closed, is preferable, and that here, as in many other areas of science, simple rules for application are probably not possible. Other experiments on open and closed questions complicate the picture somewhat further, and there is a good deal still to learn about the difference between open and closed questions—a difference as fundamental as any in the question–answer process.

3. Context Effects on Questions

The experiments described thus far have all involved some change in questions themselves. However, even when question form and wording are held constant, answers can be affected by the location of a question in relation to other questions. For example, Bishop (1987) has shown that respondents' self-reported degree of interest in politics is affected by previous political questions in the survey. If the earlier questions are about attitudes toward a number of political issues, self-reported general interest in politics tends to increase. But if the earlier questions call for answers demonstrating knowledge about politics, self-reported interest tends to decrease. The exact mechanism accounting for these changes is uncertain, for example, whether it involves mainly learning about oneself, as Bem (1972) might argue, or is mainly a matter of self-presentation to interviewers, as Goffman's (1959) writing would suggest. What is clear is that answers to survey questions are not simply reports of preexisting mental states, but are partly a result of generating responses that make sense in the immediate situation of the survey.

A second example of context effect indicates that conclusions about trends over time—which are one

of the most important contributions that surveys make—can be affected by question order. As Fig. 1 shows, a question in 1948 on whether journalists from Communist countries should be allowed to report from the USA was greatly influenced by whether it appeared before or after a question about whether American journalists should be allowed to report from a Communist country. When the Communist reporter question appeared second, the opposition to Communist reporters was much lower, no doubt because a norm of reciprocity was made salient, which called for the same treatment on both sides.

When the experiment was repeated in 1980, the same basic effect occurred, but was reduced in size because opposition to Communist journalists had decreased in the context where that question came first. As a result, conclusions about change over time are different for the two contexts. Where the Communist reporter item appears first, there is a significant increase in tolerance for such reporting. Where the Communist reporter item comes second, there is no change over time, presumably because the force of the norm of reciprocity had itself not changed over the 32-year period. Therefore, this experiment shows that a substantive finding about trends over time in attitudes can be importantly influenced by question context. Moreover, it is important to realize that responses in both contexts can be treated as valid, even though they yield different conclusions about attitude change over time.

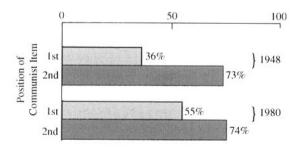
'Communist reporter' item	Do you think the United States should let Communist reporters from other countries come in here and send back to their papers the news as they see it?
'American reporter' item	Do you think a Communist country like Russia should let American newspaper reporters come in and send back to their papers the news as they see it?


Figure 1. Context effect on reporters' questions.

A final set of findings on context effects is useful to mention, because it shows the value of bringing to bear on the survey theory from both cognitive psychology and the philosophy of language. Several split-ballot experiments have been carried out on the ordering of two questions about self-reported happiness: one dealing specifically with happiness in one's marriage and the other with happiness in general. When the general question is asked second in the sequence, some experimenters have found that self-reported general happiness increases, but other experimenters have found that it decreases. Drawing on the psychological concepts of assimilation and contrast and on Grice's (1975) discussion of conversational norms (see *Conversational Maxims*), Schwarz et al. (1991) hypothesized that when the general question is interpreted by the respondent as a summary of a series of specific questions, general and specific happiness will be correlated and will point in the same direction (e.g., those reporting a happy marriage will report happiness in general). Where format or introductory sentences make it seem as though the general question is intended to be treated apart from, and not redundant with, the specific question or questions, other results can occur. A series of experiments, which cannot be summarized fully here, confirmed this complex set of hypotheses, and indicate the value of more general psychological and psycholinguistic principles in understanding questionnaire-context effects.

4. Interviewer Effects

Although most large response effects in surveys are the result of variations in question form, wording, or context, interviewers can also sometimes influence answers in a systematic way. There is little evidence that this is due to conscious ideological bias, no doubt because interviewers are trained to be neutral and nondirective in their questioning behavior. Bias due to interviewers believing that they can interpret unclear responses without probing for explanation is somewhat more likely, as shown in a classic experiment by Hyman (1954).

Still more serious is the tendency of respondents to try to give answers that they think interviewers would like to hear. At the most general level, this creates 'social desirability' bias, with respondents avoiding answers of an embarrassing or incriminating nature, for example, with regard to use of illicit drugs. Bradburn et al. (1979) describe a set of procedures to try to minimize such bias. Large response effects can also occur for more specific reasons, the best studied being differences between the perceived race of the interviewer and the race of the respondent. Black respondents indicate less hostility towards whites when the interviewer is white rather than black, and white respondents indicate more support for full racial integration when the interviewer is black rather

than white. In both these cases, it is easy to assume that cross-racial interviewing creates less valid responses, but this should not be taken for granted. It is possible that same-race interviewing is also biasing, or, from another standpoint, that it is better not to think of such attitudes as having an internal truth and an external presentation that is invalid. Instead, some attitudes might be seen as fundamentally ambivalent and therefore as genuinely varying depending on the situation.

5. Implications of Research on the Question–Answer Process

The many effects due to the question–answer process in survey research do not mean that surveys cannot yield useful knowledge. For one thing, the purpose of this article has been to highlight such effects, and therefore it inevitably exaggerates their frequency and the difficulties they pose. For another, the real lesson from recognition of such effects is the need to analyze survey data with great care, and indeed to build experiments into a questionnaire *before* analysis in order to assess possible response effects. As with any type of scientific data, a set of survey data should not be regarded naively as 'facts that speak for themselves.'

Furthermore, since questions and answers are a basic form of ordinary linguistic interaction, there is potential value in interchange between survey methodologists and linguists, especially those with an interest in pragmatics. The question–answer process in surveys can provide a valuable laboratory for linguistics, and one that, as has been shown, readily allows randomized experiments on probability samples from natural populations. Likewise, survey methodologists should be able to learn a great deal from the theories and methods of linguistics.

Corpus Linguistics and Sociolinguistics

M. Sebba and S. D. Fligelstone. Revised by W. A. Kretzschmar Jr.

A corpus (pl corpora) is a body of language material assembled with a view to extracting linguistic information from it. It may consist of data specially elicited for this purpose (for example, by interviewing a native speaker informant) or of material originally produced for some other purpose (for example, naturally occurring conversations or published texts of novels or newspaper articles). Historically, corpora were often of the elicited type and used as a basis for a phonological or syntactic description of a language. The modern field of corpus linguistics tends to use material produced with a primary aim other than linguistic study, and concerns itself more with lexical and syntactic description and issues of natural language processing than with phonological description.

1. Historical Background

The American Structuralists, who dominated North American linguistics until around 1960, based their work heavily on corpora, which often consisted wholly of elicited data. There was general agreement that the concise description of the material in a corpus representative of the language under investigation was the first aim of the linguist. The structuralist linguists proceeded mainly inductively on the basis of their corpora, and avoided as far as possible the complications of geographical and social

variation by limiting their corpora to 'one dialect' of a language. As their work was largely limited to phonology, quite small corpora were often adequate.

New notions of the goals of linguistic theory introduced by Noam Chomsky (ca. 1957) brought about a sudden change in the status of corpus linguistics. Chomsky emphasized the importance of native speaker intuitions in determining the competence of an idealized speaker–hearer with perfect knowledge of the language, making the collection of a corpus of actual utterances seem irrelevant. A corpus, the Chomskyans argued, was inadequate anyway, since it would inevitably contain an infinitely small fraction of the possible sentences of a language, and would be skewed. The inductive methods of the structuralist corpus linguists quickly came to be seen as ponderous and misguided by the Chomskyans. Corpus linguistics in this period became the pursuit of a minority of linguists and was seen as marginal to mainstream linguistics in most countries. A notable nonconformist at this time was the British linguist R. Quirk, who, in 1959, set out to create the seminal 'Survey of English Usage' (see also *Quirk, Professor Sir (Charles) Randolph*).

With the increasing availability of computers, corpus linguistics began to attract new attention and new research in the 1960s and 1970s. The capability of computers to store very large bodies of data and to provide retrieval facilities made it feasible to assemble corpora of a substantial size and to do statistical analyses of their contents. A number of projects in the USA and northern Europe were devoted to collecting corpora of printed texts intended to be representative of the contemporary state of a language. One of the first of these was N. Francis and H. Kucera's Brown University Corpus of one million words of running English text, taken from different text types, all published in the USA in 1961. The Lancaster/Oslo–Bergen (LOB) Corpus was assembled in such a way as to match exactly the Brown Corpus in size and text types, but was based entirely on texts published in the UK in 1961. In a later development, Jan Svartvik embarked on the encoding of the part of the (originally noncomputerized) Survey of English Usage, which consists of transcribed speech. This project gave rise to the London–Lund Corpus of Spoken English. These corpora are very small by current standards, but are still widely used in research owing to the perceived usefulness of their planned, 'representative' structure, a feature which contrasts sharply with some of the larger-scale collections which have begun to emerge. Due to the difficulty and expense of creating large databases of transcribed speech, most existing corpora consist only or mainly of texts, which originated in written form. The half-million word London–Lund Corpus stands out as a notable early exception to this as it consists of transcribed speech including prosodic and discoursal features.

By the early 1990s several significant projects had commenced. In the USA, the Association of Computational Linguists Data Collection Initiative (ACL/DCI) was assembling a collection of several hundred million words of text and transcribed speech to be 'captured' in a variety of ways. The ACL/DCI produced a CD-ROM, and stimulated the creation of the Linguistic Data Consortium (LDC). The LDC began in 1992 with grant funding at the University of Pennsylvania, and currently supplies numerous text and speech corpora, including some of very large scale. In the UK, work began on the creation of a more structured 100-million word part-of-speech tagged 'British National Corpus' (BNC), and also on a comparably large 'Bank of English,' a dynamic or 'monitor' corpus to be constantly updated so as to contain recent texts drawn from a fixed time span. The BNC was completed in 1994, with the aid of both commercial and public funding. As of October 2000 the Bank of English contained 415 million words. Work was also under way in several countries on the creation of an 'International Corpus of English' (ICE)—an array of parallel one million word corpora representing national and regional varieties. Currently, only the British component of ICE (ICE-GB) is readily available. Most of these projects planned to undertake linguistic annotation of at least part of the material, and to implement the guidelines of the text encoding initiative (TEI), whose aim is to ensure a standard means of encoding machine-readable texts. The TEI Consortium now manages the maintenance of the standard.

The new range of corpus applications has gone together with a new style of corpus linguistics which does not reject the role of intuition in corpus analysis, and which also allows for quantitative methods. Thus has come about a synthesis of the inductive, corpus-based methods of the American Structuralists and the intuition-based methods of the Chomskyans. The creation of large corpora has allowed for the development of statistical approaches to language, which rival the rule-based methods of the Chomskyans.

2. Some Problems of Corpus Linguistics

The memory capacity and processing capabilities of computers make storage and retrieval of texts and transcriptions relatively unproblematic. However, problems of format, ownership, and copyright have to be dealt with in the course of assembling a corpus, while there is a continuing need for new software to meet the requirements of corpus linguists. These two factors impose practical limits on the pace of progress of corpus linguistics. There are also some significant theoretical problems.

2.1 The Problem of Size

To be useful for lexicographical purposes, corpora are required which are very much larger than the one million word Brown and LOB corpora. The Birmingham Collection of English Texts, which formed the basis of the Collins COBUILD dictionary (1987), comprised around 20 million words and several dictionary publishers are now involved in projects to compile much larger corpora (see Sect. 3.1 and Sect. 4). However, no matter how large the corpus, the nature of natural language gives rise to a particular problem: that in any corpus, some 50 percent of the word types are *hapax legomena*, i.e., occur only once. In addition, there are very many words that will occur only a few times, and few words with very high frequencies of occurrence. Increased corpus size does not change this distribution. Thus, increasing the size of a corpus increases the number of *hapax legomena*, increases the number of words that occur only a few times, and increases the number of tokens for frequently occurring words.

This fact has two significant consequences. First, it is not possible to ensure that a corpus always has suitably many examples of each word; there will always be a large number of words represented by just one token or by a few tokens. Second, it is impossible to determine the true frequency of these types with low frequency of occurrence, since their relative frequency within the corpus is generally an overestimation of their true relative frequency in the corpus language. In other words, many of these words are so rare that they should not appear in the corpus at all, and they do so by chance, which exaggerates their true frequency. This last fact is not so much a problem for lexicographers as for those who need word-frequency statistics to drive parsers, taggers, or other types of natural-language processors, which are discussed below, because it may impair the efficiency of such systems.

2.2 The Representativeness Problem

For the corpus linguist to be able to make valid inferences about the language or sublanguage of the corpus, the corpus used must in principle be representative of that language. Perfect representativeness is in theory impossible, since it would involve an infinitely large corpus; corpus linguists must therefore try to maximize the representativeness of their corpora by selecting both a large enough and diverse enough sample. Where the corpus represents what is taken to be a single text type, e.g., newspaper reports or parliamentary proceedings, this may not be problematic. However, corpora which are intended to represent the language in general (e.g., nontechnical written English) are usually composed of weighted proportions of different genres, the proportions being in line with the researchers'

notions of the true relative frequency of such text types in the language as a whole. This necessarily involves some fairly arbitrary decisions about what genres merit inclusion and with what weighting. Furthermore, research into text types suggests that in terms of their linguistic characteristics, they do not cluster into groups, which correlate with the hitherto accepted notions of genre. Thus, using the traditional genre types as a basis for assembling a corpus may not be an effective way of making a corpus representative of the language as a whole. It nonetheless seems likely that 'external' criteria such as genre will continue to be used as a means of classifying the contents of text corpora in the first instance.

2.3 The Historical Problem

Another problem which corpus linguists have to address is that of static vs. dynamic corpora. Some of the older corpora such as the Brown and LOB corpora are already over 30-years-old, and thus cannot represent the state of English as it is in the early 1990s, even if they represent English as it was in 1961 (itself doubtful). The need for up-to-date information is especially clear in the case of lexicography, but also applies to other uses of corpora. The task of planning corpora, which are dynamic and subject to constant update, now lies before corpus linguists.

3. Some Applications of Language Corpora

3.1 Lexicography

The value of computerized corpora for dictionary making was clear to lexicographers and a number of widely used dictionaries have been based on large corpora of English text; for example, the American Heritage dictionary (based on reading matter for secondary schools), and the Collins COBUILD English dictionary. This trend has continued, as dictionary publishers have made use of both public (e.g., BNC) and private corpora, and some publishers (such as Oxford University Press in the *New Oxford Dictionary of English*) have even adapted the style of dictionary entries to reflect experience with corpora.

3.2 Linguistic Research

The opportunities which corpora offer for extracting and statistically validating information about the language under study have led to their use by syntacticians, discourse, and conversation analysts, and (for spoken language corpora) phoneticians.

Much of the pioneering corpus-based English language research of recent years has been documented under the auspices of ICAME (International Computer Archive of Modern English), which continues to promote the exchange of information

and resources in the area of corpus research and corpus creation.

The use of corpora as a data resource of 'real language' is also becoming widespread in the field of course planning for language instruction and even in language teaching itself.

A primary tool in all of these pursuits is a search-device usually called a 'concordancer/browser,' which facilitates interaction between the analyst and the corpus material. Such a device allows the user to examine or extract from the corpus items which conform to a specified pattern, e.g., a word, a word ending, a part-of-speech marker, or various combinations of these.

3.3 Applications in Computational Linguistics

Corpora are also being exploited in the development of language-processing tools, which are of primary interest to computational linguists and computer scientists. These efforts have strong commercial implications in speech recognition and speech synthesis for computer interfaces.

3.3.1 Tagging and Parsing

The task of applying a single part-of-speech tag to each word in a body of running text serves to illustrate the potential value of corpus processing. Here, probabilistic methodology has had notable success. Using hidden Markov model techniques it is possible, given a string of words and some rules for assigning a set of possible tags to each of those words, to estimate to a high degree of accuracy the most likely sequence of tags for that string on the basis of 'bigram' probabilities for tag sequences, i.e., the probability of a given pair of tags occurring in succession. For a set of, say, 100 part-of-speech tags, a 'probability matrix' is required with estimates of the likelihood of each of the 10,000 possible sequences of two tags. Such a matrix can be derived empirically given a previously analyzed corpus of sufficient size. Thus it was that the tagged Brown Corpus (tagged using a variety of heuristics and subsequent manual correction) was used to derive a probability matrix for the tagging of the LOB Corpus using a probabilistic tagger 'CLAWS' with an accuracy level of about 96 percent, Trigram (i.e., tag-tag-tag) probabilities are in principle a better data source with which to drive a tagging device, and are still computationally tractable, but the derivation of such probabilities from observed frequencies would require a corpus of massive proportions.

Accurate parsing of sentences using corpus-derived probability matrices has proved to be a much more difficult problem. Some approaches involve a phrase structure analysis of sentences, whilst others merely simulate such an analysis by treating grammatical structures as a series of tags, where a tag may be either a part-of-speech marker as described above, or

the beginning or end marker of a grammatical constituent. Whichever approach is used, the rarity of many grammatical structures makes parsing difficult to automate due to the lack of reliable frequency data (cf. *hapax legomena*, above).

3.3.2 Machine Translation

Monolingual corpora may be used indirectly in machine translation as sources of lexicographical or other information, which is incorporated into some component of the machine translation system, or to test the effectiveness of the system on an unseen text. Corpora may also be used in a more direct way, where parallel bilingual corpora (i.e., corpora consisting of texts and their translations) already exist. Where new material to be translated is substantially similar to that already in the bilingual corpus (e.g., in the case of technical manuals, which are constantly updated but remain largely the same), translation of a new sentence may be reduced to finding a similar sentence in the corpus and so finding directly its translation in the parallel corpus of translations. Accurate machine translation is hampered by the same distributional facts, which impede automatic tagging and parsing, and in addition must manage the problem of sense disambiguation (selection among various possible meanings for words). It must be considered still to be in an experimental stage.

3.3.3 Speech Recognition and Speech Synthesis

A prosodically and grammatically annotated corpus of spoken language may be used for the derivation of statistically weighted rules to be applied in the production of authentic sounding speech from written text. Recognition of ordinary speech by computers has improved steadily over the years, but remains inadequate for most tasks in daily life. However, for words separated by short pauses, probabilistic approaches closely related to those used for tagging (see above) have proved effective in enabling computers to disambiguate speech signals, i.e., to decide what for a given signal, is the most likely corresponding lexical item, even when a very large vocabulary is used. A calculation of the probability of various sequences of two or three words enables the computer to update its hypotheses as more signals are processed.

The application of corpora to various kinds of natural language processing tasks seems to be a growing trend in a field where logic-driven procedures have tended to be favored over the probabilistic approaches to which machine-readable corpora readily lend themselves (see articles in Lawler and Aristar Dry 1998). There are few these days who are not at least willing to acknowledge that language corpora (as opposed to 'laboratory sentences') represent a useful test bed against which natural

language processing (NLP) systems may be evaluated.

4. Corpora Present and Future

The two broad types of corpus exploitation distinguished in this article (the computer-driven statistical or other processing vs. the researcher-driven interactive) are very much related. On a practical level the point is worth elucidating given that one goal pursued by the computational linguist is to develop a grammatical tagger, so success in this task enables the creation of a tagged corpus. This tagged corpus in turn places a new resource at the disposal of the interactive user. In fact, analyzed corpora are proving to be very popular among researchers. The creation of corpora tagged for part of speech is largely a solved problem, but progress in creating parsed and semantically analyzed corpora is much slower and recourse to semimanual methodology is still preeminent. In spite of the unresolved theoretical questions, and the shortcomings of many resources currently available, corpora have demonstrated their usefulness to researchers and are here to stay. Widespread recognition of this has given rise to a concentration of effort on the creation of suitably structured and formatted computer corpora of sufficient size to be of value to the research community as a whole.

Even given its status as an international language, the predominance of English-language corpora over all others is striking. In countries where English is not a first or second language (for example, Norway), research may be concentrated on English-language corpora rather than local-language corpora. While the strong interest in English-language corpora is likely to remain, the increasing availability of suitable hardware and software is likely to lead to more corpora of other languages, and even multilingual corpora for research purposes.

Data Collection in Linguistics

J. E. Miller and R. Cann

Accurate descriptions and adequate theories require reliable data. Equally, purposeful and fruitful data collection requires a theoretical framework. Data and theories interact: data searches are guided by theory but theories are modified or abandoned in the light of data. This article focuses on the collecting of data, in which success depends on assembling an adequate sample of texts and/or informants and on obtaining reliable data from the informants.

1. Basic Problems of Data Collection

Analysts must not rely on their intuitions unless with respect to simple constructions in their native language, as is often done in the early stages of formal models. Experience has shown that when the examples become more complex, intuitions become less clear, and there is the unavoidable difficulty of unconscious bias towards an attractive hypothesis.

Data must be collected from other sources; of course, this has always been essential for investigators working on languages other than their own or working on nonstandard varieties.

The collection of data in any language will be vitiated unless attention is paid to variation (see *Sociolinguistic Variation*). Is a given construction typical of (possibly excluded from) informal conversation or academic writing? Is a given word typical of informal conversation or poetry? Is a given word only to be used by women? A database for an account of word order in written English will be misleading if a large proportion of the data is from the metrical Psalms.

The study of spoken language requires attention to such factors as the speaker's age, sex, and social class, the audience's age, sex, and social class, the speaker's provenance, the relative authority of speaker and

769

audience, the topic under discussion, the setting and degree of formality of the interaction, the nature of the interaction (conversation, debate, lecture, etc.). Some of these factors are relevant to written texts too, but they are of crucial importance for spoken language.

2. Sampling Texts and Informants

Ideally, distinctions such as those mentioned in Sect. 1 are reflected in data collection. Investigators of written language must classify different types of written text, e.g., detective novels, serious literary novels, school textbooks (but this is a complex task; see Biber 1988) and ensure that equal amounts of data are collected from each type.

For spoken language the factors listed in the last paragraph in Sect. 1 should be taken into account and informants collected to represent the sets defined by possible combinations of variables; e.g., middle-class Scottish women between 50 and 60 with higher education as opposed to women of the same class, age, and provenance but without higher education. In towns and cities with well-established populations sets of potential informants can be established on the basis of areas defined by social and demographic information in census reports, with the actual informants being chosen via personal approaches by the investigators. When the factors involved are more subtle—such as children born in a particular town as opposed to children who are incomers, the informants can be found through organizations such as churches, youth groups, schools, sports clubs, etc.

Apart from the practical difficulty that appropriate informants are not always available, or at least not in sufficient number, the notion of social class is controversial. How does the occupation-related notion of class connect with status, which need not relate to occupation? How are the class and status of women best determined? With respect to language, is it fruitful to regard individual speakers as representing a particular large social class or as belonging to a much smaller social network, as described in Milroy (1987) (see *Social Networks*)? These questions cannot be answered here but they show that sampling a population of speakers is a delicate and complex matter.

3. Collecting Reliable Data

For both written and spoken language there are two basic sources of data; a corpus of texts and elicitation tests. Only a corpus of texts will give an idea of the typical features of particular types of language, whether of academic textbooks or informal conversation, but individual syntactic constructions or lexical items can only be fully investigated by means of elicitation tests. For certain types of data a corpus combined with tests gives the best results. In the investigation of the phonetics and phonology of

groups of speakers, for instance, the standard technique is to extract the pronunciation of key lexical items by tests—asking informants to read a list of words and a passage of connected prose—and to obtain data relating to conversational speech by encouraging informants to talk spontaneously. Spontaneous speech is encouraged either by asking informants about exciting and dangerous experiences they may have had or by recording informants in informal surroundings talking to close friends. Obtaining the latter type of data requires trust between informant and interviewer, overt recording with the participants' knowledge and permission, and confidentiality—the deletion from the tape of confidential or private information provided accidentally.

3.1 Working with a Corpus of Texts

Gathering a corpus of texts has four major advantages: analysts cannot influence existing written texts and can easily avoid influencing spoken texts that they are recording by allowing the informants to talk for themselves. A representative sample of the relevant genre can be gathered. A large enough corpus will present unexpected constructions that might not occur to the analyst relying on intuition—this is regularly and frequently experienced by researchers testing and extending speech technology. A given corpus is typically useful for more than its original purpose—no body of data gathered by researchers in the last 20 years has been exhausted and many still await thorough exploitation (see *Corpus Linguistics and Sociolinguistics*).

There are disadvantages; collecting a corpus is time-consuming, in particular a spoken corpus. The informants must be recorded and the recordings transcribed, one hour of conversation requiring approximately 9 hours of transcribing in order to produce a basic transcription in terms of words. Transcribing even the cleanest recording of speech is laborious, but dialogues always involve interruptions, overlapping speech, repetitions, and drops in pitch which greatly complicate the task. The transcription must be coded for the relevant properties such as general type of construction, e.g., WH, TH, or contact relative clause; grammatical properties, e.g., past tense, gerund, animate noun, textual position. Transcriptions (indeed, any text) can be coded for any property. It is important that the analyst have a clear idea beforehand about what properties are relevant so as to avoid repeated revisions of the coding. However, once the coded transcription is stored on computer this labor reaps a large reward in the ease and accuracy with which concordance programs locate all the examples of any word or coded construction and store not only the relevant examples but fragments of the context in which they occur. With the latter information the analyst can quickly pick out the most interesting examples and

discard the less interesting. The final but unavoidable drawback, especially for syntactic research, is that even a very large corpus may contain few or no examples of a given construction. The solution lies in elicitation tests, as described in Sect. 3.2.

3.2 Elicitation Tests

The native speakers of a language have intuitions about what is acceptable in their language but tapping these intuitions is not straightforward. The intuitions of any given native speaker are limited in extent and reliability and the limitations vary across speakers. Even inside these limitations intuitions vary from one speaker to another, say with respect to whether a given combination of words is syntactically acceptable or with respect to the exact interpretation of a phrase or sentence.

A different problem is that native speakers' acceptability judgments may not match their practice. Most native speakers of a language are unaware of the syntax they use in speech and in informal writing such as personal letters, and their acceptability judgments may draw on their knowledge of good writing practice. That is, the acceptability judgments of a given native speaker may not correspond with the syntax produced by that speaker.

A final problem arises from the nature of elicitation tests. Suppose informants are asked to judge whether 20 sentences are acceptable. The order in which the sentences are presented may influence the answers, and the influence may be quite unpredictable.

All these problems can be circumvented. That different informants have different intuitions obliges the investigator to use enough informants—a minimum of 30—so that the major and minor patterns become clear. Possible effects of order can be trapped by arranging the examples in four different random orders (using tables of random numbers) and assigning each order to a quarter of the informants. Analysis of the results will reveal whether a particular answer to a given question is associated with a particular order.

The use of different types of elicitation tests reveals mismatches between speakers' acceptability judgments and what they actually say and write. Informants can be asked to provide data in various ways:

(a) by being given a sentence conveying a certain meaning followed by a paraphrase with a gap which has to be filled, e.g., *Do you want me to phone the doctor?* with the paraphrase _____ *I phone the doctor?* where the gap can be filled by *shall, will,* or *should*;

(b) by providing a continuation for a sentence, e.g., *I must go to Glasgow because_____, I've got to go to Glasgow because_____, I have to go to Glasgow because_____.* The object of these examples was to find out whether the informants' continuations indicated an aware-

ness of the differences in meaning between *must, have to* and *have got to* as described in grammars of English;

(c) by making a forced choice, e.g., insert either *have to* or *must* in *I____go to Glasgow because I want to see the Cathedral* and *I____ go to Glasgow because I'm appearing in Court*;

(d) by describing a picture or scene. This is appropriate, e.g., for eliciting the use of prepositions. Computer graphics make it possible to elicit descriptions of movement and to adjust details of a scene in order to discover the limits on the use of a particular preposition.

Reliable judgments of acceptability likewise require subtlety of method. To prevent informants falling into a routine or guessing what is at stake, the important examples should be interspersed with distractors, examples unconnected with the key ones. Examples can be presented in lists or they can be incorporated into a piece of text which the informants are asked to judge. Investigators of nonstandard language should avoid asking informants if they find the examples acceptable, as this question triggers prejudices and fears. Rather, they should be asked if they have heard or seen the examples.

For all elicitation tests it is important that the informants be prevented from comparing the answers to the various questions and from thinking about the 'best' answer to each question. Both these problems can be solved if the informants are taken through a given test at a speed which forces them to answer quickly and gives no time for reflection on previous answers. The appropriate length of time per question depends on the type of question and the complexity of the examples but can be determined by means of a pilot test. Although the tests described here are written, they can yield (and have yielded) reliable information about nonstandard spoken varieties of a given language.

When data has been collected by some or all of the methods outlined above, analysis will show whether the acceptability judgments by given informants match the informants' own performance. Central and peripheral patterns of usage can be recognized and statistical tests can be applied to discover which results are statistically significant.

Field Methods: Ethnographic

M. L. Apte

The fundamental division in sociocultural anthropology is between ethnology and ethnography. Ethnology subsumes the development of conceptual categories and frameworks, methodology, cross-cultural/comparative studies for creating broad typologies, formation and testing of interpretive and explanatory hypotheses, and general theory building. The principal aim of ethnology is to analyze and explain the diverse and multifaceted nature of human existence and the underlying common biological and psychological foundations. In these endeavors ethnology is dependent on ethnography: the study, analysis, and description of individual sociocultural systems all over the world. Ethnography (see *Ethnography of Speaking*), in turn, uses ethnological frameworks and analytical tools for data-gathering and descriptive studies.

1. Nature and Objective of Ethnography

Ethnographic studies entail the collection and analytical description of relevant data concerning individual societies and cultures, i.e., geographical location, climate, flora and fauna, techniques of adaptation to natural environment, technology, food production and food habits, the institution of marriage, family and kinship, child-raising and socialization practices, social roles, religion and rituals, economic transactions, patterns of language structure and use, interactional strategies in social relationships, the political system, folklore, and artifacts; in short, all the major aspects of a sociocultural system. Ethnographic studies also record and analyze the ideology, worldview, and cultural values of the people being studied. Such data are crucial for an understanding of how the individual sociocultural systems are structurally, functionally, and ideologically integrated.

It is an established tradition in sociocultural anthropology that researchers actually live among the members of a culture being studied. This enables them to collect the kind of ethnographic data necessary for their analysis. Anthropological literature is full of both brief and extensive accounts of hundreds of societies and cultures. Ethnographic research and data-gathering is known as fieldwork, and an anthropologist doing fieldwork is called an ethnographer. The techniques generally employed by an ethnographer in collecting data constitute the ethnographic methods.

2. General Nature of Ethnographic Research

Ethnographic research by its very nature is explorative and open-ended. The ethnographer needs time to get adjusted to the field situation and also to establish rapport with the people whose culture s/he wants to study since their acceptance of the investigator is crucial for the success of the enterprise. A major reason for the explorative nature of ethnographic research is the very unstructured nature of the field situation. The researcher has no clear-cut idea of how s/he will be received, what kinds of opportunities will exist to conduct research, what aspects of individual life and community activities will prove easily accessible or difficult to study, and whether or not important information will be made available. No matter how conversant the ethnographer may be with the existing anthropological literature on the community s/he wants to study, s/he will be in for the surprises, joys, and perhaps sorrows of the fieldwork experience. There are also differences of opinion regarding the value of existing literature to the ethnographer about to engage in fieldwork, and familiarity mixed with a questioning attitude towards the published sources is the best solution. Initially, ethnographic research may remain rather unfocused except for the broad and somewhat vague objectives the ethnographer has in mind.

The reception accorded to the ethnographer, her/his judgment of what is and is not accessible, the personal relationships established over a brief period of time with certain members of the community, the estimated duration of stay in the field, and the ethnographer's own research preferences will help dictate the overall nature of her/his research. Unlike pre-1960 fieldwork, which generally studied whole sociocultural systems, contemporary anthropologists generally go to the field with a focus on investigating specific sociocultural aspects. Even then, it is necessary to have a rudimentary knowledge of the other related characteristics of a culture. This is known as the 'holistic' approach, which emphasizes that any single aspect of a sociocultural system cannot be fully understood and analyzed without taking into consideration its relationship to the structural and functional whole of the system.

3. Major Ethnographic Field Methods

The primary ethnographic methods for fieldwork are participant observation, extensive interviewing, systematic note taking and record keeping, recording folklore and other such materials, taking photographs and/or making films, and collecting artifacts. While mechanical and electronic equipment and tools such as tape recorders, cameras, and video recorders

772

are often used in fieldwork, they cannot be used as substitutes for participant observation which is inductive in the sense that after observing a few instances the ethnographer forms tentative generalizations regarding the existing behavioral patterns, and the nature of events, phenomena, causes, relationships, etc. Thus specific observations and interviews constitute the basis of many generalizations.

Although the standardization of ethnographic methods is desirable, it has not been possible in the past. The reasons are many. Traditionally, anthropologists have depended heavily on a qualitative and personal approach to ethnographic fieldwork, and have not systematically formulated the kinds of methods that could be used in the field. Before the 1970s anthropologists believed that 'immersing' oneself in the field situation and establishing good rapport with the people to be studied would lead to a successful gathering of data. They also believed that fieldwork was a unique experience and much depended on the personality, temperament, perseverance, and imagination of the individual ethnographer. Therefore, it was believed that the systematic formalization of ethnographic methods was not possible.

This view gave way during the 1980s and there now exists much literature on research methodology in sociocultural anthropology. A major part of it is devoted to the systematic elaboration of ethnographic methods and their advantages and disadvantages. The development of new conceptual frameworks for the purpose of devising systematic anthropological research methods has also reduced the mystery of anthropological fieldwork.

3.1 Participant Observation

This is the primary method of ethnographic research and involves both direct participation and/or observation of as many of the activities of the community under study as possible. Living in the community enables the ethnographer to utilize this method on a daily basis. The wider and more varied the range of the ethnographer's observation and participation, the better will be his or her ability to understand the sociocultural nature of the activities and their relationships. The ethnographer needs to observe the routine activities of different types of individuals: men and women, children, young and old people, political leaders, religious authorities, tool makers, traders, etc. It is equally important to observe special events which often signify important ritual periods in the life cycle of the individuals and the community. The ethnographer may not get a second chance to observe such special events if they are annual in nature. It is at such occasions that the ethnographer has the opportunity to observe and

make sense of the behavior of the specialists in the community.

A major problem in using the participant observation method is that the ethnographer cannot be in all places at all times and thus misses observing many activities. Much depends on the nature of the community itself. If the ethnographer is studying a small village community where the daily activities take place in the presence of many people, then a stroll through the village at different times of the day will help the ethnographer to know what people do at specific times. If, on the other hand, the ethnographer is studying an urban population, it is impossible for him or her to know what is going on everywhere. One way of overcoming this problem is to vary systematically the kinds of social interactions to be observed and the situations in which they occur. The ethnographer may not have access to all such situations, however, and depending on her/his age, sex, social status, and foreignness s/he may or may not be able to participate in or observe certain types of social interaction.

Once the ethnographer has become familiar with the workings of the society, s/he needs to be selective in choosing those social situations that are likely to provide greater insights into the workings of the culture. S/he needs to use her/his observations to develop specific questions to be asked. In other words, observation and participation, whenever possible, should be systematic and not haphazard. There should be a genuine effort to make certain that such observation and participation will help the ethnographer gain a greater understanding of sociocultural patterns.

Participation in the activities of the community occurs in varying degrees. Full participation is not always possible, primarily because the ethnographer is not always cognizant of the appropriate behavior necessary for participating in an event. This is usually the case with special events, in which participation is possible only because of knowledge acquired over many years. Not even all the indigenous members of a community are able to participate in such events.

3.2 Field Notes and Record Keeping

Participant observation by the ethnographer must be followed by extensive and detailed notes of all the events that the ethnographer has witnessed. Without such notes no systematic data collection and analysis is possible. Reliance on memory would be a grave fault for any ethnographer. The more extensive and detailed the field notes, the higher the degree of accuracy and the greater the opportunities for checking and confirming ethnographic facts. It is also crucial to date the field notes so that the ethnographer can check the changing nature of

the data collection as s/he becomes familiar with the people and is accepted by them.

Field notes should include not only observed facts but also explanations and interpretations presented by members of the community regarding both daily and special events. Without such explanations the ethnographer cannot gain an understanding of the emic viewpoint which is crucial for acquiring insight into the ideologies and values of the community.

Despite the necessity of making detailed field notes, it is not always possible for the ethnographer to be ready with notebook and pencil to write down every detail of an event being witnessed or participated in. Such an attempt may be seen as an intrusion. Making notes may also distract the ethnographer from actually observing the event. Note taking is a judicious process at which the ethnographer may become more proficient the longer the time spent in fieldwork. Another technique that may be employed is the jotting down of key concepts or words regarding the numerous sequential happenings in an event. These serve to remind the ethnographer of the details later.

If note taking is not possible at the actual time an event occurs, it is generally a good practise to put aside a certain part of the day to write down observed events. Evenings are usually better suited for such a purpose. It is important, however, that daily records be kept. An alternative is to speak into a tape recorder as the event unfolds. Such recorded data should always be transcribed later so that it is not lost through technical errors or accidents.

3.3 Interviewing

Mere observations of sociocultural events in a community do not always make sense and are rarely enough for the ethnographer to gain sufficient knowledge of the community. Events alone cannot make sense without an understanding of the cultural explanations behind them. Therefore, it is necessary for the ethnographer to conduct systematic interviews with members of the community. Such interviews can be informal or formal. Informal interviews are primarily those where the ethnographer asks for and receives information, explanations, etc., while observing events. As the ethnographer gathers additional factual data, she or he begins to formulate specific questions. Eventually, she or he may have many questions concerning the diverse aspects of the society and culture. In particular, she or he may be seeking answers to things that do not make sense to her or him, but seem perfectly sensible to members of the community. The ethnographer also needs to verify facts already gathered. Interviews need to be conducted with individuals such as community leaders, well-known storytellers, religious specialists, craftsmen, and others to gather community lore, myths, stories, songs, proverbs, and other materials

that throw light on the cultural values, ideologies, and worldview of the community.

It is crucial that formal interviewing be conducted systematically and that these interviews be structured. It is helpful for the ethnographer to maintain a regular systematic interview schedule. If possible, all formal interviews should be recorded so that opinions, information, and explanations can be recalled for checking and confirmation. If this is not possible, interviews should be written down verbatim as far as possible. Much depends upon the proficiency of the ethnographer in the indigenous language. Without a mastery of the local language, the ethnographer often has to depend on individuals who are bilingual and can translate both the questions and the answers. Much can be lost, however, in such a translation, depending on the ability of the bilingual translator and his or her judgment as to what should or should not be translated. One of the first tasks that most ethnographers undertake, immediately upon arrival in the field or, if possible, before going to the field, is to learn the language of the community they want to investigate. Once in the field, language proficiency can rapidly increase because of the constant exposure and the need to use it. Collection of extensive linguistic texts of diverse types is often a major objective of the ethnographer. The ethnographer may even work exclusively on the indigenous language with a representative native speaker.

Along with structured, formal interviews, it is useful to find opportunities for unstructured, open ones, especially on occasions when people gather together just to talk. An innocent question at the right time can get people talking, and the more discussion that takes place among those present, the better the nature of the information gathered, since differences of opinions and the accuracy of factual information can be checked. In many instances it is preferable for the ethnographer to be a silent listener after prompting a discussion on a particular topic.

3.4 Filming and Photography

Along with detailed field notes, photographs of the numerous diverse activities of the people in the community are useful both for visual impact of special events and also as mnemonic devices. Photographs supplement and strengthen verbal descriptions of events. In recent years, more and more ethnographers have engaged in making ethnographic films as such equipment as video cameras, tape recorders, and movie cameras have become sophisticated enough to be readily operated on batteries, circumventing the need for local electricity. Since the mid-1960s, hundreds of ethnographic films have been made depicting the lives of communities around the world. It is important to emphasize, again, that

photographs and films are supplementary materials and cannot replace the meticulous field notes and records kept by the ethnographer.

3.5 Collection and/or Description of Material Objects
In all cultures the results of technology are evident in the equipment, tools, and variety of objects used by the people. Such things as types of houses, household goods, cooking utensils, bedding, toys for children, clothing, agricultural and/or hunting and fishing tools, art, ritual objects (such as masks, sculptures, drawings), and modes of transportation are examples of the kinds of material objects about which it is useful to collect detailed information (such as their structure, the materials used in making them, and their functions).

4. Selection of Informants

Since, in almost all field situations, ethnographers depend heavily upon the assistance of individuals from the culture being studied, it is usually necessary for them to select a few individuals who can act as their assistants. Such individuals, called 'informants' in ethnographic literature, are often primary sources for data that are not readily accessible to the ethnographer. They are also the ones who provide indigenous viewpoints, explanations, and interpretations of acts, events, and things. Thus they are crucial for achieving the ethnographer's principal objective. Selecting an informant can often be very tricky. Generally, the main qualities that are necessary in an informant are an ability to articulate ideas and views and the possession of a large amount of cultural information about the people being studied. An informant should also be of good standing in the community. A person of marginal status is not always privy to all relevant information.

Ethnographers generally do not depend on a single informant, but use several individuals as temporary informants as and when the need arises. It is generally preferable to have informants of different backgrounds, ages, and sexes, so that diverse viewpoints are available and individual bias can be reduced. Several informants are also necessary for checking information given by any single individual. Despite the need for an ideal informant, preferably a bilingual who is proficient in the language of the ethnographer, the field situation often dictates that the ethnographer has as an informant the individual whom s/he gets to know well or who cultivates the acquaintance of the ethnographer. It is possible that in some communities many individuals may vie for the position of being the ethnographer's informant because it may be seen as a financially advantageous and prestigious position. In such a situation, the ethnographer may have a hard time making the selection.

5. Nature of Ethnographic Data

In the past, ethnographic data have tended to be qualitative. However, ethnographers have increasingly undertaken surveys and thus gathered quantifiable data. These data can be grouped under particular headings, for example, number of households, members in each household, acreage under cultivation, kinship networks, and so on. Other kinds of data are also important. Not all data are primary, that is, based on the actual observations or actually collected by the ethnographer. Much is often secondary, that is, consisting of information provided by several informants. Data can also be interpretational, textual, linguistic, and so on. What is crucial in all instances is the reliability of the data. The ethnographer must constantly check and validate it.

6. Future Directions

Because of the importance of explicit methodology as recognized in sociocultural anthropology during the early 1990s, many treatises on ethnographic methods have been published. While an attempt has been made to standardize field methods, the very nature of ethnographic research is such that this is a nearly impossible task. However, the refinement of ethnographic field methods will continue as anthropologists increasingly recognize the importance of both qualitative and quantitative data, and become increasingly proficient at judiciously mixing the two.

Field Methods in Modern Dialect and Variation Studies
K. Hazen

Field methods in modern variation studies can be divided into two major stages: planning and doing. Although this may seem simplistic, investigators must realize that planning is theory in practice and should be given appropriate time allotment in the project. A clear, principled, and written methodology should guide both stages. Although a clear methodology does greatly facilitate replication of the study for future scholars, more importantly it allows for the most efficient data collection possible.

The choice of methodology impacts on the type of data collected and the quality of the access to the speakers: studying a language variety from a discourse analysis perspective should yield different data than that of lexically based dialectology. Methodology depends on the objectives of the study, and field methods should be strictly guided by these objectives. These field methods in turn determine the recording approach (e.g., written survey, audio recorded, or video recorded), the potential subjects contacted, and the questions fieldworkers may ask (Milroy 1987).

1. Goals

In line with the awareness of the general project's methodology, several questions need to be asked to focus the study: is there a linguistic goal, a sociological goal, or a sociolinguistic goal (e.g., impetus for language change)? Will there need to be quantitative assessment, or only qualitative? What kind of language data are the goal (Wolfram 1993)? One point to keep in mind when establishing the kind of data desired is that the vernacular, in the sense of least self-monitored speech, is not the holy grail of sociolinguistic research it once was. Within any human's language production, a variety of styles are produced, and all of these styles can tell researchers about the language variation of both the speaker and the community. In addition, the shifting between more and less standard features in an interview can be an important indication of identity connections (Hazen 2000a, Wolfram et al. 1999).

Several different kinds of studies can be made of any community, and before researchers approach the task of gathering language data, research into the community on several different levels should be made, including social composition, socio-geographic boundaries, and economic issues. Depending on the site of the research, information may be drawn from census tables, city directories, graveyards, local leaders, or visitors bureaus.

What data to gather is an important methodological question, and one that is of course determined by the goals of the research. However, some hierarchies of data collection are more logical than others. Recorded interviews generally precede a matched-guise test. A written survey of potential lexical items or vowel mergers (e.g., *Do ⟨pin⟩ and ⟨pen⟩ rhyme?*) or participant observation can be undertaken at any point during a research project. A reading passage and word list most often follow an interview since such tasks will draw attention to the subject's language and normally cause a shift in style. However, if a style shift of this type is the object of study, researchers may want to open a series of interviews with such a task in order to assess at what point in an interview a speaker shifts to a different style.

2. Communities and Individuals

An overarching question to any variationist project is whether the researchers are investigating the community or individual speakers. Fieldwork can yield a more sociological study or an identity study (Eckert 2000). Variationists investigate how nonlinguistic factors possibly affect linguistic variation in both speech communities and individual speakers. Of course speech communities are composed of individual speakers, but the goal of many variationist studies has been to describe and explain the variation of the speech community as an entity (i.e., the grammar of the speech community). In their argument against the homogeneous idiolect being the only theoretically viable entity for linguistic study, Weinreich et al. (1968) present the study of synchronic and diachronic variation as a study of the grammar of the speech community (see *Sociolinguistic Variation*).

For these two variationist approaches, that of the speech community and that of the individual, the nonlinguistic factors influencing language variation are cast in different ways. Drawing from sociology, the speech-community approach investigates social factors which divide a speech community: age, sex, ethnicity, and social class have become the standard social factors correlated with dependent linguistic variables. By this model, a person is an intersection of social groups: a certain subject would be seen as female, Native-American, older, heterosexual, and middle class. In contrast, drawing partly from Goffman's study of 'self,' the work of anthropological communication studies, and social psychology, the individual approach encapsulates nonlinguistic factors in a person's identity (see *Goffman, Erving*).

Investigating identity allows inclusion of speakers' attitudes and beliefs in the explanation of language variation, which can enhance traditional speech community studies. The overarching identity of a speaker usually comprises subidentities of age, gender, ethnicity, social class, sexual orientation, and communities of practice (Holmes and Meyerhoff 1999).

3. The Sociolinguistic Interview

After clarifying the theoretical underpinnings of the methodology, the researchers should craft the most predominant form of data collection in variationist studies, the sociolinguistic interview. Any socio-linguistic interview should be seen as a type of community interaction.

Before approaching the community, the research-ers need to ask several questions: how does the community feel about the study of their language? Is this project initiated from outside the community and would community involvement make a difference in the collection of data? Potential interview subjects may be contacted in numerous ways, but essentially the least effective manner is to approach potential subjects as a stranger, while the most effective manner is to approach them through another member of the community (see *Social Networks*). If an insider can introduce the research team to the community, then many social hurdles can be avoided altogether. The most plausible first contact for many communities might be with members of the commu-nity who have moved outside the area but still keep up good relations back in the home community: those who have traveled to school outside the area, or those who have moved for employment reasons. People who can live outside of their home community may be more open to the kinds of research variationists' conduct and might be able to introduce the researchers to members of the home community. The danger in the 'friend of a friend' approach is that original contacts in a community may be harmful to the researchers' later efforts; initial contacts may be disliked by the remainder of the community and the researchers' association may damage the project. As with other matters, the research team's knowledge of the community, including major social networks, will save time and effort when a full-scale interview effort is made.

Perhaps Wolfram's Principle of Linguistic Gratu-ity would be useful in some communities for collecting data: investigators who have obtained linguistic data from members of a speech community should actively pursue positive ways in which they can return linguistic favors to the community (see *Fieldwork Ethics and Community Responsibility*). If the researchers approach the community with the honest and open intent of helping the community with the data gathered (e.g., the rights of a linguistic minority community, or an educational program for local schools), the community may respond more enthusiastically to the collection of data.

Researchers should also be aware of topics that are taboo for certain social groups. It may be that with certain ethnic, religious, or socioeconomic groups, certain topics are not appropriate for questions and conversation. A breech of local protocol may render an otherwise promising interview useless. For this reason, no one question fits every community. For example, Labov's danger of death question never worked in the research on the Outer Banks of North Carolina and has been found to be 'a really bad idea' with gang member interviews in California (Mendo-za-Denton 1997, Wolfram et al. 1999).

One important tool in the interview is crafted long before recording begins: the sociolinguistic module. A sociolinguistic module should focus on matters of importance for the subjects and have a series of language questions, including specific questions about language variation patterns of the area. For this reason, preliminary inquiries about the language variety, if not preliminary interviews, should be made in order to craft the language questions, reading passages, and word lists.

Before an interview begins, researchers should explain themselves. One often helpful and truthful approach to fieldwork is one of ignorance; research-ers can present themselves as ignorant but having a desire to learn about the community. Often research-ers are outsiders who can quite honestly don the cloak of ignorance. This is but one approach for the researchers to present themselves, but others also include some reflection of the research goals (e.g., working to improve the education of the local community or the education of a wider audience about the community). Researchers must keep in mind, however, that the background assumptions of the community will have the biggest effects on the access and quality of the data.

In any kind of interview, researchers will want to establish situations where the subjects can talk about themselves and the social groups they belong to. Researchers may want to provide a situation where the self-interest of the speakers motivates them to talk about the things that interest them most. To establish this situation, the interview subject must trust the researchers. To establish trust, the research-ers should clearly identify who they are, their motivations, and their desires. Most researchers start an interview with the formal questions and then progress to questions about the community. In this rhetorical context the researchers are listeners inter-ested in the community, but interview subjects respond to this situation with different degrees of enthusiasm. If people feel themselves engaged com-fortably in a real conversation, they are much more open to tell their stories. Overall, the goal of engaging

a community for sociolinguistic research is to observe language variation, from the most restricted phonological alternations to the most widely held social language norms. The constraints on quality and the quantity of the observation are what the researchers hope to maximize.

How long should a recorded interview be? The vague but truthful answer is as long as is needed for the type of research being conducted. For most variationist studies, an interview needs to be as long as needed to get a high enough count of a feature to provide for quantitative analysis. For example, if the research is of word final stops (released, unreleased, glottalized), a half hour of conversation will normally yield a sufficient number of tokens for analysis; but if the research is on past tense *be*, then at least an hour of interview time needs to be taken and the interviewers should guide the subject to tell stories from the past.

4. Participant Observation

It is best to keep in mind that an interview is not just contact with a person; it is contact with a community. For sociolinguistic research, participant observation may or may not help the researchers reach their objectives (see *Field Methods: Ethnographic*). Although it is generally true that the more researchers observe a community, the better the social evaluation, whether or not the researchers need to conduct themselves as participant observers depends on the goal of the study. If the research team wants to know how stigmatized language features are used in a community, the more observation the better the study; however, if the research team is focused on phonetic variation of word-final voiceless stops, then a series of audio recordings will suffice.

How long should researchers spend in an area for effective participant observation? Most likely, there is an inverse relationship between how different the community under study is from what the researchers know and how long they should stay. A native research team from the United States would have to spend longer in a rural community in South Africa than a rural community in West Virginia in order to describe the relevant sociolinguistic details. Some good sociolinguistic studies have been conducted with little participant observation (several weeks) while others have involved over a year of participant observation. Part of the goal of participant observation is to integrate oneself into the community; the other part is to make better (or more) observations than possible with only short visits to the community. Participant observation may also help considerably in improving researcher's identity with the community.

Researcher identity plays an important role in the type of data collected and in access to the data; however, the researcher's identity is not something to be altered like an actor changing costumes. Rather than manipulating their identity, researchers should comprehend how their identities affect the data. In other words, they should not avoid the effects but understand the impact of their presence and role in the setting being studied. In addition, the community views the researchers in terms of what it has experienced. Thus, if it has had bad experiences with universities or simply with people of the researchers' 'type,' then the researchers' position is compromised before ever making contact. The perception of the researchers is a two-input process. Researchers offer up who they are through formal presentations but also through many other factors such as how they dress and their own language variety; the researched community will categorize the researchers according to their own norms. Knowing the community's norms is an important preliminary step, but the researchers are limited to working within the boundaries of those norms. This approach is summed up in the principle of socio-rhetorical field methodology: to produce the most efficient fieldwork, researchers must understand the community's view of them, the varied perceptions of the language under study, and the community's differing self-perceptions (Hazen 2000b).

As practical advice, researchers can at best understand how the community perceives itself, the research, the researchers, and the institutions they represent. Honesty with subjects is of course important, and researchers must be willing to address with the community any area that may cause distrust. Although some communities may eventually be unapproachable, a clear perception of how the community will react to invasive sociolinguistic research will at least eliminate surprises, which is perhaps the best researchers can hope for.

Fieldwork and Field Methods

U. Canger

The term 'linguistic fieldwork' will make most people think of a linguist in the bush studying some Native American language, or some native language in Africa, Asia, or Australia (see *Field Methods: Ethnographic*). However, the term may just as well refer to the work of a dialectologist mapping out the geographical dialects in the UK (see *Dialect and Dialectology*), or of a sociolinguist investigating spoken variations of sociolects in the country's capital (see *Sociolinguistic Variation*). Doing fieldwork simply means collecting linguistic data where language is spoken.

1. What is Specific to Linguistic Fieldwork?

Specific to linguistic fieldwork is—first of all—that it takes place in the field rather than at a desk; and the 'field' here refers to nothing but the natural environments of spoken language, i.e., wherever people meet and interact. What constitutes the specific field of a given study is defined by the linguist.

Another feature which is crucial for linguistic fieldwork is that the fieldworker—knowingly or not—performs a very first analysis in merely collecting the language data (see *Data Collection in Linguistics*). Whether he records speech on tape, or directly writes down what he hears, he selects and limits his data, and he cuts off material; in transcribing, i.e., writing down the data—directly or from recordings, he will make a great number of decisions, often inadvertently, and those decisions form part of any later more conscious analysis.

Linguists who study written language, on the contrary, base their study on material which has already been through this very first analysis, performed by writers, and the inventors and revisers of the given writing system, the alphabet. This very first analysis, in both these cases, is thus the privilege as well as the burden of the linguistic fieldworker.

2. A Brief History of the Fieldwork Tradition

The traditions for linguistic fieldwork come from the USA; here linguistics has its roots in the work of anthropologists who early in the twentieth century were faced with the task of analyzing a very large number of Native American languages.

The linguist, Franz Boas (see *Boas, Franz*) started the tradition of linguistic fieldwork. He saw it as a goal to have recorded as many of the Native American languages as possible before the advancing American frontier made this recording impossible.

Franz Boas explains how the study of language serves a practical purpose, 'the service which language lends us is first of all a practical one—a means to a clearer understanding of ethnological phenomena which in themselves have nothing to do with linguistic problems.' But he considers the study that focuses on the actual languages no less important than the practical knowledge of them, 'because the fundamental concepts of human language are not distinct in kind from ethnological phenomena; and because, furthermore, the peculiar characteristics of languages are clearly reflected in the views and customs of the peoples of the world.'

His students, Edward Sapir (see *Sapir, Edward; Sapir–Whorf Hypothesis*) and Leonard Bloomfield introduced a third purpose for working with the Native American languages: in the study of different language families they both wanted to test—on unwritten languages—the 'comparative method' which had been successfully applied in the historical study of Indo-European languages (see *Sound Change*).

Finally, with a developing interest in the autonomous structure of language, linguists began to collect language data for synchronic analyses, wanting to use them in this theoretical study of language.

In Europe, linguistic fieldwork was practiced by dialectologists who looked for the details of language change in the minute variation found in dialects (see *Dialect and Dialectology*); they traced the variation and history of individual sounds and words. The term 'fieldwork' was not used to characterize their work, but they too collected language data in the field, and the methods they used were closely related to those applied by linguists in the USA. A major difference between the two traditions stems from the

fact that European dialectologists were already familiar with the language(s) from which they collected data.

In the 1950s, an interest in language as a social phenomenon, to be studied in a wider context (see *Language as a Social Reality*), returned and steadily increased; the area of linguistic fieldwork expanded to be included in sociolinguistics and ethnolinguistics (see *Ethnography of Speaking; Ethnicity and Language*). Above all, the American linguist William Labov (see *Labov, William*) has discussed, developed, and refined the methods used in the collection of linguistic data.

The development of the tape recorder and more recently of the video recorder has opened the way for entirely new methods, and has also influenced the amount of data collected. The balance between collecting the material and transcribing and analyzing it shifted: before the tape recorder, all texts were dictated and simultaneously subjected to a basic analysis, whereas in the early 1990s the linguist will tape-record much material in the field which he will transcribe and analyze only after he has returned to his desk.

These technical innovations have also drastically changed the scope of questions to which the linguist can hope to find answers. The minutest physical detail of spoken language can now be scrutinized. These new possibilities have led to new approaches and to a refinement of the methods. Stylistic and other variation in the language of the individual speaker and between groups is studied.

3. Field Methods

The methods employed in linguistic fieldwork depend entirely on the situation of the language to be studied and on the goals of the study. In working with a language which has no bilingual or multilingual speakers, the linguist must use the monolingual method: by pointing at objects he will hope to have the speakers say something about them or optimally tell him what they are called, and thus begin to collect the names of things. By listening to the speakers and by trying to imitate what he hears, he will approach the phonology. Gradually, some interaction between the speakers and the linguist will emerge; the linguist will pick out longer expressions, and be able to identify them and test his understanding by substituting one word for another. This is a slow and demanding process.

In most cases, however, the linguist is able to locate some speaker who knows at least scraps of a second language and if the linguist also knows this second language, he will work through that. Otherwise, he must use an interpreter who will get him from his own language to the target language, the one to be studied. The optimal situation is to begin the work with a speaker who—in addition to his own language—knows that of the linguist.

The type of research program which the linguist has set up for himself and the prevailing concept of what language is, is even more decisive in dictating approach and method than the kinds of speakers available. Linguists who want to collect a restricted and well-defined body of data, such as lists of words to be used in a dialect survey or in comparative studies of a language family will not plan to spend much time in each locality, and will often be satisfied with working with only one informant. Terrence Kaufman, who has amassed material for an etymological dictionary of the Mayan languages for over twenty-five years, devised a method for collecting—in a short period of time—as exhaustive a corpus of words as possible for each language:

> Mayan languages all share the characteristic that the majority of root morphemes are monosyllabic. Since the number of phonemes is not large, it is a feasible project to systematically generate all possible rootshapes and then verify their existence or non-existence with an informant, at the same time establishing appropriate glosses for the existing root, and establishing the class of each root. The possible root-forms are generated by permuting all possible consonant and vowel combinations, according to the canonical patterns of root morphemes for the particular language.
>
> (Kaufman 1968:1)

During the structuralist period, when language was studied as an autonomous object independent of speakers and context, linguists would work with a limited number of informants, sometimes only one, and would often ignore the surroundings; in some cases they even preferred to move the informant out of his natural setting and take him to a location which was more convenient to the linguist.

3.1 A Full Grammar—Few Informants

In working with a hitherto undescribed language with the purpose of making a grammatical description of it, the linguist will begin by asking for simple words and write them down with all the phonetic detail he is able to distinguish; subsequently, he will attempt to analyze these fine phonetic transcriptions, and by asking the informant to repeat words that seem similar or that may sound identical to him, the linguist will try to identify the *phonemes* and to arrive at a crude and first description of the phonological system; he will decide on a less detailed, but systematic way of transcribing the language, a writing system which notes all the sounds that carry a meaning distinction. While he continues to check and test his hypotheses about the phonology, the fieldworker will go on to collect more vocabulary and data for his description of the morphology. Soon, he will attempt to obtain short texts: these will give rise

to innumerable questions to the informant concerning both morphology and syntax. He will go on refining his understanding of the phonology, add on to the vocabulary and to his knowledge about the morphology and syntax.

To keep track of the progress of the analyses and the order in which the data are collected it is a general practice to carefully date everything written down and to enter all the information in notebooks; the vocabulary is copied on to filing slips and kept in alphabetical order so that words can be easily located. Many fieldworkers have taught one or several of their informants to write in their own language and have had them write texts and transcribe tape-recorded stories.

3.2 Narrow Focus—Many Speakers

In this traditional type of fieldwork, the objective is to collect as much vocabulary and as much data about the phonological and grammatical structure of the language as possible. In sociolinguistics, which focuses on variation (see *Sociolinguistic Variation*) and the use of language in relation to the speakers and their interaction in the community, the phenomenon studied may be restricted, but encompassing a great number of speakers. An example of this kind of fieldwork is the now famous department store experiment carried out by William Labov, who in this study focused on the pronunciation of *r* among New Yorkers, often called the 'fourth floor method.' He describes it in this way:

> The application of the study of casual and anonymous speech events to the department-store situation was relatively simple. The interviewer approached the informant in the role of a customer asking for directions to a particular department. The department was one which was located on the fourth floor. When the interviewer asked, 'Excuse me, where are the women's shoes?' the answer would normally be, 'Fourth floor.'
>
> The interviewer then leaned forward and said, 'Excuse me?' He would usually obtain another utterance, '*Fourth floor*,' spoken in careful style under emphatic stress.
>
> The interviewer would then move along the aisle of the store to a point immediately beyond the informant's view, and make a written note of the data.
> (Labov 1972: 49)

3.3 Problems

In studies where all the data are collected in fieldwork situations and are based on the speech of informants, the choice of informants and the relationship between the linguist and the informants is important and a potential source of all kinds of problems, both purely practical and psychological but also of methodological consequence (see *Native Speaker*).

If the purpose of the study is to collect a vocabulary or to deliver a structural description of the grammar, then the informant must be able to understand the questions and the basic ideas of the linguist; through the work he will learn and gradually become a better informant. But if the purpose is to study the minute stylistic and other variations, then the speakers should be as unaware of the linguist as possible. This problem is expressed in what William Labov has called

> the *Observer's Paradox*: the aim of linguistic research in the community must be to find out how people talk when they are not being systematically observed; yet we can only obtain these data by systematic observation.
> (Labov 1972: 209)

Fieldwork Ethics and Community Responsibility
B. Johnstone

By inclination and as a matter of necessity, sociolinguists have always been sensitive to the ethical dimensions of fieldwork and thoughtful about their responsibilities to the communities they study. However, definitions of ethical fieldwork and community responsibility have changed somewhat

with the times. We are now aware, in a way we have not always been, of how choices about research methods are grounded in assumptions about knowledge, authority, language, and humanity, and we now consider more carefully what such assumptions imply about the best ways to work.

Some sociolinguists still think of themselves as objective observers, whose job is to examine the people and the linguistic facts they study in as detached a way as possible. They can then return to their scientific communities, once fieldwork is over, with new knowledge about the causes of patterns of linguistic behavior. Others, however, ask questions like these: What is knowledge? Are there social and linguistic facts in the world which any disciplined scientist could observe, or are facts, sociolinguistic and otherwise, partly a consequence of often unspoken traditions about what to pay attention to and how to describe things? If so, who establishes such traditions of thinking and seeing, how are they perpetuated, how are they challenged and changed? What is the relationship between the kinds of knowledge scholars develop and circulate and kinds of knowledge developed and circulated by the people we study? If researchers and the people they study are all experts in one way or another, what is the researcher's role vis-à-vis that of the people we have sometimes called 'subjects'?

1. Traditional Fieldwork Ethics: Protecting And Serving

According to the ideas about science and scholarship that prevailed in the 1960s and 1970s, the role of a social scientist was to observe and interpret the behavior displayed by the community under study. Early sociolinguists followed this model, for the most part. They took care to adhere to the basic ethical imperative not to cause harm to those they studied, as sociolinguists continue to do, typically using pseudonyms to protect their privacy, for example.

In early sociolinguistic work, as in the field research in dialectology and descriptive linguistics that preceded it, members of the community under study were sometimes involved in the process of data-collection as assistants, who might help interview others or record or organize data, or as 'informants'—native speakers of the local language or variety who were hired to answer researchers' questions about linguistic structure or meaning. Other people in the community might be involved only as objects of scrutiny or manipulation: as interviewees, as subjects participating in controlled studies or otherwise observed and/or recorded. Although procedures for insuring informed consent are more stringent now than they once were, most sociolinguists have always explained to the people they studied, in one way or another, what they were doing and how the research would proceed, and they

have often gone back to the community later on to report to them what they found.

From the beginning, however, sociolinguists have also tried to use what they learned for the benefit of the people they studied. William Labov, who studied the speech of African American youth in a poor New York neighborhood, entered US educational debate to speak out about African American linguistic structure and traditions of language use (Labov 1982). Other variationists have also designed and carried out educational programs meant to make students and teachers aware of the systematicity and value of stigmatized ways of talking (Wolfram et al. 1999). John J. Gumperz (1982) tried to improve workplaces for immigrants to the UK by sensitizing employers and co-workers to sociolinguistic difference. Dell Hymes' (1981) interest in Native American discourse was partly motivated by his wish to preserve important linguistic traditions and texts. Many sociolinguists have taken their results to the public in speaking and writing about issues such as prescriptivism, miscommunication, and linguistic discrimination, in interviews, films, books and articles meant for general audiences.

People continue to be drawn to sociolinguistic work not only for intellectual reasons but also by the desire to understand and help right things that seem wrong. It continues to be important to find ways of systematically incorporating 'service in return' (Rickford 1997) into the design of sociolinguistic research. Newer debates about the sources of truth and the nature of scholarly authority have highlighted the range of possible ways of conceiving of the relationship between sociolinguists and the people they study, the people with whom they work, and the people for whom the products of their work are intended.

2. 'Communities' and Individuals

The research of sociolinguists' typically focuses on groups of people who are thought likely to have something in common in a linguistic sense: speakers of a particular language or variety or a particular combination of languages or varieties; people who all live or work in the same 'speech community,' 'discourse community' or 'community of practice'; and people engaged in the same linguistic activity. It is important to bear in mind, however, that any decision to study a group of people has the effect of creating a group of people. Humans are not born into groups to which they then always and invariably 'belong'; human identity and social organization are flexible, so that a particular individual orients to different identities, different sets of ideas, and different social activities at different times. Even relatively immutable facts about people such as their physical appearance or age can be relevant at some

moments and irrelevant at others. The labels sociolinguists typically use in grouping people for study—labels such as 'Spanish speaker,' 'East Asian,' 'lower middle class,' and 'female'— can make social and linguistic categories seem more fixed and permanent than they are, and such labels may fail to correspond to any of the ways the people in question actually group themselves, when they do.

Failure to think carefully about which social and linguistic categories are relevant, and under what circumstances, to the individual people in whom we are interested, can make sociolinguists liable to misunderstand what is happening. It can also cause confusion and hostility, as people find themselves mislabeled and treated as if their behavior were entirely predictable. Like all other scholars, sociolinguists need to come to conclusions that are potentially generalizable across sets of people or situations, but doing this inevitably means describing people as cogs in a sociolinguistic machine. This deprives them of free will, an aspect of their humanity that many people especially value. Because of this, an important aspect of 'community responsibility' is to bear in mind that 'community' is always an abstraction, and that the object of study is ultimately a set of particular individuals with particular motivations and behaviors.

3. Community Members as Co-Workers

Because of the general shift in sociolinguistics from more social-scientific ways of explaining things to more ethnographic ones, it has become increasingly important for sociolinguists to find ways of eliciting the beliefs and perceptions of the people they study in addition to eliciting their behavior. This means that community members are acting as co-researchers in more ways.

Since 'insiders' who study their community thereby partly reposition themselves as outsiders and 'outsiders' acquire roles inside the community by virtue of studying it, the distinction between outsiders and insiders is never completely clear. It may be that in some cases the ideal researchers are themselves members of the community, since insiders have access to 'local knowledge' (Geertz 1973) and local resources in a way outsiders do not. An effective research team may, in other cases, include insiders and outsiders, with complementary orientations and skills.

In many cases, sociolinguists involve the people they study by using them as sources of validation, consulting with them via procedures sometimes called 'member checking.' In sociolinguistic work, this sometimes involves 'playback' or 'feedback' procedures in which tapes are played for the people who were recorded, or similar people, and they are

asked what they think was happening and why. Sometimes the people being studied have even more authoritative roles. Although research participants in sociolinguistic work are rarely (if ever) treated as the sole experts—we do not simply transcribe and publish their explanations of things—folk linguistic expertise is often explicitly drawn on, because sociolinguists have come to see that local ideas about language and local ways of attributing social meaning to linguistic phenomena cannot be predicted on the basis of larger social or linguistic patterns, and that access to local knowledge of this sort is crucial for understanding sociolinguistic processes. Sociolinguists have explored numerous ways of drawing out local knowledge; many borrowed from the participant observation techniques of sociocultural anthropology. They include, for example, paying increased attention to local talk about talk and other representations of speech, as in 'stylings,' parodies, and performances of various other kinds.

4. Uses of Research Findings

It was once thought that the purpose of scholarly research was to uncover the truth, in order to add to humanity's store of knowledge. Now that many sociolinguists are no longer convinced that there are absolute truths or that knowledge is a single ever-expanding inventory of scientific facts, new and challenging questions have arisen about the uses of research.

For one thing, we need to think in new ways about the nature and the distribution of expertise. It seems more and more important to many researchers to find systematic ways of incorporating community expertise into the process of scholarly inquiry. Researchers in some fields have adopted 'participatory' research practices that include ways of insuring that all participants in the research— researcher and community members alike—take part not just in data collection and analysis but also in theory-building. Such practices are not widely used in sociolinguistic work, in part because non-linguists' ideas about language—the idea that speakers of stigmatized dialects are stupid, for example, or the idea that there is a single correct way of talking— often strike linguists as not only wrong but potentially harmful. We have often been tempted to dismiss local expertise telling non-linguists, in effect, that their ideas are understandable but ours are correct.

This has repeatedly failed to work. For example, the controversy of the 1990s over 'Ebonics,' or African American Vernacular English (see *Ebonics and African American Vernacular English*), showed that Americans had exactly the same misconceptions about language and ethnicity as they had 25 years previously, despite sociolinguists' repeated

educational efforts over those years. An ongoing challenge for sociolinguistics, then, is to find more effective ways of building bridges between community and scholarly expertise.

Another new question about knowledge has to do with the role of social and political critique in the research process. Skeptical that value-free, disinterested, 'pure' description is possible, some sociolinguists suggest the need for greater explicitness about our social and political beliefs, preferences, and goals. Some 'critical sociolinguists' (see *Critical Sociolinguistics*) argue that social and political change should be our expressed goal. The community's wishes are not always the same as the researcher's—community members may want stigmatized varieties to disappear, for example, while sociolinguists are interested in preserving linguistic diversity—and this poses another continuing challenge.

Interactional Sociolinguistic Research Methods

N. Berenz

Research methods in interactional sociolinguistics (IS) involve several stages: a preliminary period of ethnography; the main processes of data collection, transcription and analysis; and a final effort of confirming the findings as consonant with current knowledge. These methods have been developed and applied by John Gumperz, his collaborators and students primarily, although not exclusively, in cross-cultural encounters in institutional settings to yield important insights into the role of implicit cultural presuppositions in human interpretative processes (see *Ethnography of Speaking; Discourse in Cross-linguistic and Cross-cultural Contexts*).

Because the research objective of IS is the explication of human communicative practices and interpretative processes, it is important for the researcher to be familiar with the cultural presuppositions held by the subjects whose conversational exchanges will be analyzed. This background information is gathered through reading previous studies and literature, where possible, and—crucially—participant observation within the relevant social groups.

1. Interactional Sociolinguistics and Conversation Analysis

In including background information IS differs from conversation analysis (CA), its better-known

intellectual 'first cousin.' We believe that the deeper and broader the analyst's understanding of the background against which an interaction takes place, the more accurately the present encounter can be interpreted. An anecdote from a presentation of scholarly work in the CA tradition illustrates this point. The researcher played an audio recording of a particularly acrimonious exchange between a man and a woman that supported a hypothesis about the gendered nature of conversation. Only during the question-and-answer period that followed the presentation did it emerge that an element of conflict was typically part of the different professions of the two participants and further that these participants had a number of encounters previous to the one analyzed in which the level of conflict had escalated by degrees to the acrimonious heights recorded. This background information did not alter the facts of the interaction with respect to interruptions, for example. Rather than supporting a hypothesis that men interrupt women more than they are interrupted by them, a more nuanced analysis of the interaction viewed against the background information would be that a man may enact his irritation towards a woman differently than he would towards another man (see *Conversation Analysis; Gender and Language*).

2. Institutions and Settings

We acknowledge, of course, that the concept *social group* is itself problematic, given the ever-increasing complexity of social interaction in a world where modern modes of transportation and communication have blurred traditional ethnic, gender, and social class boundaries. Nevertheless, we can predict with considerable confidence which aspects of participants' social personae may be relevant in particular types of encounters. For example, a Korean and a German, both members of the international business community, may share some presuppositions about business that will facilitate understanding during business negotiations; communicative difficulties are likely to arise instead from differences in presuppositions generally held by people of Korean or German cultural background. On the other hand, either businessperson may encounter communicative difficulties in conversation with their rural kinfolk, which arise from different presuppositions held by traditional or cosmopolitan populations.

When analysis is carried out in an institutional setting, such as a school, corporation or hospital, that institution will have its own particular 'culture' and 'community.' The researcher develops a basic understanding of the institution during an initial period of interviewing and participant observation by gathering information on the institution's history, social characteristics, everyday practices, and goals. From this information, in tandem with information on participants' backgrounds, we isolate encounter types and generate working hypotheses.

For example, in the school setting, we would expect to find classroom lessons, parent–teacher conferences, chatting among students in the lunchroom or playground, peer evaluations of teachers, and so on. We might hypothesize, drawing on pre-existing knowledge, that a power differential between the teacher and the student will be relevant, such that the teacher can be expected to play a bigger role than the students in classroom conversational management, including topic choice and turn allocation. We may find such an expected power balance to be upset, however, in situations where other social characteristics of participants challenge the 'institutional order.' In a classroom in a prestigious private South African school serving a largely affluent, white population, a black teacher may not be readily accorded the same status by the students as his or her white counterpart. In this situation, the teacher's typical rights and responsibilities for conversational management may be subverted by cultural presuppositions based on perceived extra-institutional social group membership, with the result that an unusually heavy classroom discipline burden falls to the teacher. A performance evaluation of the teacher's classroom management skills may fault the teacher as an individual, when in fact the problem is more general.

3. Gathering Data

The initial phase of determining encounter types and generating working hypotheses is followed by the collection of audio or video recordings of social interaction within the particular setting. Here the researcher must attempt to minimize the effect of the intrusion of recording equipment on the naturalness of the interaction, while at the same time fully informing the participants about the presence of recording equipment and securing their informed consent (see *Fieldwork Ethics and Community Responsibility*). Once consent has been given and equipment is in place, experience has shown that participants soon become used to it and the recorded interaction proceeds quite naturally. Despite the complications inherent in collecting audio- or video-recordings, the careful turn-by-turn analysis required by IS is only possible with such data. Ethnographic fieldnotes detailing aspects of the physical and social setting are important, but they never substitute for the interactive details of an encounter captured on tape. These recordings, ranging from a few minutes to several hours, are the major input to the analytic process.

The recordings are the raw data that are categorized into encounter types whose labels such as *job interview, medical consultation, parent–teacher conference* invoke associated folk knowledge about the nature of the interaction and the relationships likely to hold between participants. Folk knowledge is never identical to the implicit schematic knowledge that participants rely on to inform their own conversational moves and to interpret each other's. A job interview may not be solely a cataloguing of the applicant's job-related skills, but may briefly veer off into areas of interest or experience shared by interviewer and interviewee, such as a mention of a mutual acquaintance or an expression of enthusiasm about a preferred leisure activity. Although these 'digressions' may not be part of folk knowledge about the process of job interviewing, they may have significant impact for the development of rapport between the participants that will influence their later assessment of the success of the encounter (Erickson and Shultz 1982). The lack of isomorphy between labels and interpretive practices necessitates the caution that there is never a one-to-one relationship between a signal and a meaning. The interpretation of a particular conversational move is based on knowledge of what has gone before and is supported by information that follows.

4. Transcription and Analysis

The next step after labeling the encounter is to segment it into thematically coherent and empirically

785

boundable events that have beginnings, middles, and ends. The ends are of particular importance because they provide information on what participants might have inferred and how such inferences were cued. Oftentimes, segmentation can only be accomplished after listening or viewing the tape several times. Gradually we discover such passages through turn-by-turn scanning of the content and rhythmic organization of the encounter as a whole. Some events will be more clearly bounded than others, and it is these clearly bounded events that are the focus of analysis.

The basic unit of sequential analysis is the speaking turn: that string of utterances produced by a single speaker and bounded by other speakers' turns. Within the speaking turn we find the informational phrase: a rhythmically bounded, prosodically defined chunk, a lexical string that falls under a single intonational contour. An informational phrase will, in the clearest cases, be a syntactic unit that carries meaning and is bounded on either side by a pause. In the many less than clear cases found in everyday conversation, rhythmic and thematic organization serves to determine phrase boundaries.

With the analytic construct of informational phrase in mind, we now turn to the labor-intensive activity of transcription. The first step is to isolate and mark informational phrase boundaries throughout an event or portion thereof, followed by another pass (or several more) through the recording to mark interactively salient features of the talk. A detailed explanation of the system and example transcripts can be found in Gumperz and Berenz (1993).

The purpose of the transcription system is to capture those perceptual cues that research has shown participants to rely on in their on-line processing of the speech stream. We do not seek to be exhaustive in our representation of the characteristics of talk, but rather to capture the interactionally meaningful features. With respect to pausing, for example, we listen to the encounter to become familiar with the general rhythm of the talk, and then we mark pauses as deviations from expectation. A Native American job applicant with an Athabaskan background, being interviewed by a General American English speaker, may seem to be slow to respond to the interviewer's questions. Either participant's normal rhythm could be taken as the default and the other's rhythm marked as deviations from that norm. For clarity and to allay as much as possible the bias introduced by the act of selection, the assignment of default value should be made explicit in an introductory note to the transcript. We recognize that transcription is not a theory-free endeavor (Ochs 1979), and we maintain that no transcription is final. The best record of what transpired in an encounter will always be the recording. With recent technological advances, it becomes more possible to distribute actual segments of the recording to readers whose interest in the data and analysis exceeds the limits inherent in transcription.

As noted at the outset, IS differs from CA in its inclusion of background information. The two also differ in the importance attributed to prosody and paralinguistic signaling. Focusing on cross-cultural encounters, IS practitioners find that culturally-based prosodic and paralinguistic variation contributes significantly to communicative breakdown. CA practitioners, on the other hand, have tended to examine interactions between participants who may be assumed to share significant socio-cultural background, where signaling conventions are likely to be less variable. A third difference between the two traditions is what I might call *check-back*. By this I mean that, with a preliminary analysis in hand, we solicit further information from an assistant or consultant who shares social group membership with a participant in the interaction, particularly if that participant's behavior remains inexplicable. By way of example, consider a case reported by Gumperz (1982: 30). A black graduate student, in the company of several other black and white graduate students, approached him after an informal seminar, asking, 'Can I talk to you for a minute? I'm going to apply for a fellowship and I was wondering if I could get a letter of recommendation.' Gumperz replied, 'Come along to the office and tell me what you want to do.' The student's next turn, 'Ahma git me a gig,' (roughly equivalent to 'I'm going to get myself some support') seemed to Gumperz a puzzling switch to African American Vernacular English, until he discussed the incident with other graduate students familiar with African American interpretative traditions. From the further information provided, Gumperz interpreted the code switch as signaling a shift in the audience to whom the student was addressing himself. To those who shared the tradition, he was letting it be known that his request could be understood as a typical one for a minority student trying to get support to carry on with his studies.

We see then that IS research methods anchor the findings of the detailed analysis of everyday conversation in the matrix of socio-cultural understandings, participants rely on in their on-line interpretative efforts.

Literacy: Research, Measurement, and Innovation
D. Wagner

Research on the causes and consequences of literacy and illiteracy has grown dramatically since the 1980s, yet much more needs to be known. Since there exists a great variety of literacy programs for an even larger number of sociocultural contexts, it should come as no surprise that the effectiveness of literacy programs has come under question, not only among policymakers and specialists, but also among the larger public. How effective are literacy campaigns? What is the importance of political and ideological commitment? Should writing and reading be taught together or separately? Should literacy programs include numeracy as well? Is literacy retained following a limited number of years of primary schooling or short-term campaigns? How important are literacy skills for the workplace? Is it important to teach literacy in the individual's mother tongue? These and similar questions—so central to the core of literacy work around the world—remain without definitive answers, in spite of the occasionally strong rhetoric in support of one position or another. Basic and applied research, along with effective program evaluation, are capable of providing critical information that will not only lead to greater efficiency in particular literacy programs, but will also lead to greater public support of literacy programs.

Research on literacy can reveal key policy areas which need to be addressed, as well as methodologies for assessment and monitoring which will be crucial in the coming years. This entry summarizes some of the major areas of literacy research and measurement, and offers some critical areas for future innovation.

1. Literacy Research in Global Perspective

There are three general domains in literacy work that are likely to be the subject of greater attention and will determine to a large extent whether attempts at improving global literacy will be successful. Each of these is reviewed below.

1.1 Defining Literacy: Operationalization for Measurement

With the multitude of experts and published books on the topic, one would suppose that there would be a fair amount of agreement as to how to define the term 'literacy.' On the one hand, most specialists would agree that the term connotes aspects of reading and writing; on the other hand, major debates continue to revolve around such issues as what specific abilities or knowledge count as literacy, and what 'levels' can and should be defined for measurement. The term 'functional literacy' has often been employed, as originally defined by Gray (1956: 19): 'A person is functionally literate when he has acquired the knowledge and skills in reading and writing which enable him to engage effectively in all those activities in which literacy is normally assumed in his culture or group.'

While functional literacy has a great deal of appeal because of its implied adaptability to a given cultural context, the term can be very awkward for research purposes. For example, it is unclear in an industrialized nation like the UK what level of literacy should be required of all citizens. Does a coal miner have different needs than a barrister? Similarly, in a Third World country, does an illiterate woman need to learn to read and write in order to take her prescribed medicine correctly, or is it more functional (and cost effective) to have her school-going child read the instructions to her? The use of the term 'functional,' based on norms of a given society, is inadequate precisely because adequate norms are so difficult to establish.

An adequate, yet more fluid, definition of literacy is '...a characteristic acquired by individuals in varying degrees from just above none to an indeterminate upper level. Some individuals are more or less literate than others, but it is really not possible to speak of literate and illiterate persons as two distinct categories' (UNESCO 1957). Since there exist dozens of orthographies for hundreds of languages in which innumerable context-specific styles are in use every day, it would seem ill advised to select a universal operational definition. Attempts to use newspaper reading skills as a baseline (as in certain national surveys) may seriously underestimate literacy if the emphasis is on comprehension of text (especially if the text is a national language not well understood by the individual). Such tests may overestimate literacy if the individual is asked simply to

787

read aloud the passage, with little or no attempt at the measurement of comprehension. Surprisingly, there have been relatively few attempts to design a battery of tests from low literacy ability to high ability which would be applicable across the complete range of possible languages and literacies in any society, such that a continuum of measurement possibilities might be achieved. UNESCO, which provides world-wide statistical comparisons of literacy, relies almost entirely on data provided by its member countries, even though the measures are often unreliable indicators of literacy ability. However, there were new attempts in the 1990s to undertake literacy surveys in a comparative and international framework in some industrialized nations (OECD/Statistics Canada 1995).

At least part of the controversy over the definition of literacy lies in how people have attempted to study literacy. The methodologies chosen, which span the social sciences, usually reflect the disciplinary training of the investigator. Anthropologists provide in-depth ethnographic accounts of single communities, while trying to understand how literacy is woven into the fabric of community cultural life. By contrast, psychologists and educators have typically chosen to study measurable literacy abilities using tests and questionnaires, usually ignoring contextual and linguistic factors. Both these approaches (as well as history, linguistics, sociology, and computer science) have value in achieving an understanding of literacy. There is no easy resolution to this problem, but it is clear that a broad-based conception of literacy is required not only for a valid understanding of the term, but also for developing appropriate policy actions (Venezky et al. 1990).

Because literacy is a cultural phenomenon—adequately defined and understood only within each culture in which it exists—it is not surprising that definitions of literacy may never be permanently fixed. Whether literacy includes computer skills, mental arithmetic, or civic responsibility will depend on how public and political leaders of each society define the term and its use. Researchers can help in this effort by trying to be clear about which definition or definitions they choose to employ in their work. For overviews of literacy in international context, see Wagner and Puchner (1992), Wagner (1992), Wagner et al. (1999).

1.2 Acquisition of Literacy

The study of literacy acquisition has been greatly influenced by research undertaken in the industrialized world. Much of this research might be better termed the acquisition of reading and writing skills, with an emphasis on the relationship between cognitive skills, such as perception and memory, and reading skills, such as decoding and comprehen-

sion. Further, most of this work has been carried out with school-aged children, rather than with adolescents or adults. Surprisingly little research on literacy acquisition has been undertaken in the Third World, where researchers have focused primarily on adult acquisition rather than on children's learning to read. This latter phenomenon appears to be a result of the emphasis to promote adult literacy in the developing world, while usually ignoring such problems, until quite recently, in industrialized societies.

Despite these gaps in the research literature, certain general statements are relatively well established as to how literacy is acquired across different societies. In 1973 Downing published *Comparative Reading*, which surveyed the acquisition of reading skills across different languages and orthographies. He found that mastery of the spoken language is a typical prerequisite for fluent reading comprehension in that language, although there exist many exceptions. Another finding is that in many alphabets children first learn to read by sounding out words with a memorized set of letter–sound correspondences. It is now known that there are many exceptions to this generalization. There are, of course, languages which are not written in alphabets (e.g., Chinese and Japanese). There also appear to be large individual differences in learning styles within literacy communities. Finally, many individuals can read and write languages which they may not speak fluently.

Some specialists have stressed the importance of class structure and ethnicity/race as explications of differential achievement among literacy learners. Ogbu (1978), for example, claimed that many minority children in the United States are simply unmotivated to learn to read and write in the cultural structure of the school. This approach to understanding social and cultural differences in literacy learning has received increased attention in that it avoids blaming the individual for specific cognitive deficits (as still happens), while focusing intervention strategies more on changes in the social and political structure of schooling or the society.

Finally, it has been assumed that learning to read in one's 'mother tongue' or first language is always the best educational policy for literacy provision, whether for children or adults. Based on some important research studies undertaken in the 1960s, it has generally been taken for granted that individuals who have had to learn to read in a second language are at a disadvantage relative to others who learn in their mother tongue. While this generalization may still be true in many of the world's multilingual societies, more recent research has shown that there may be important exceptions. In one such study, it was found that Berber-speaking children who had to learn to read in Standard Arabic in Moroccan schools were able to

read in fifth grade just as well as children who were native speakers of Arabic (Wagner 1993). Adequate research on nonliterate adults who learn to read in a second versus a first language has yet to be undertaken.

In sum, considerable progress has been made in understanding the acquisition of literacy in children and adults, but primarily in industrialized societies. Far less is known about literacy acquisition in a truly global perspective, and in multilingual societies. Since the majority of nonliterate people live in these areas of the world, much more needs to be known if literacy provision is to be improved in the coming decades.

1.3 Retention of Literacy

The term 'educational wastage' is common in the literature on international and comparative education, particularly with respect to the Third World. This term typically refers to the loss, usually by dropping out, of children who do not finish what is thought to be the minimum educational curriculum of a given country (often 5 to 8 years of primary schooling). Most specialists who work within this area gather data on the number of children who enter school each year, the number who progress on to the next grade, those who repeat a given year (quite common in many Third World countries), and those who quit school altogether. The concept of wastage, then, refers to those children for whom an economic investment in educational resources has already been made, but who do not complete the appropriate level of studies.

The issue of literacy retention is crucial here, for it is not actually the number of school leavers or graduates that really matters for a society, but rather what they learn and retain from their school years, such as literacy skills. When students drop out of an educational program, a society is wasting its resources because those individuals (children or adults) will not reach some presumed threshold of minimum learning without losing what has been acquired. Thus, retention of learning (or literacy, in particular) is a key goal of educational planners around the world. There are as yet only a small number of research studies published on this question, and their results are highly contradictory. Some show that there is a 'relapse' into illiteracy for those who have not received sufficient instruction, while other demonstrate no serious loss (Wagner 1998a).

2. Literacy Measurement

2.1 Areas of Debate in Literacy Assessment

In order to provide worldwide statistical comparisons, UNESCO (UNESCO 1996, Wagner 1998b) has relied almost entirely on data provided by its member countries. These countries, in turn, typically rely on national census information, which most often determines literacy ability by self-assessment questionnaires and/or by the proxy variable of years of primary schooling. Many specialists now agree that such measures are likely to be unreliable indicators of literacy ability. Nonetheless, through the 1990s, change in literacy measurement has been slow in coming, even though some initiatives have been undertaken.

There is considerable diversity of opinion as to the usefulness of classifying individuals in the traditional manner of 'literate' versus 'illiterate.' Several decades ago, when developing countries began to enter the United Nations, it was common to find that the vast majority of the adult populations of these countries had never gone to school nor learned to read and write. It was relatively easy in those contexts to simply define all such individuals as 'illiterate.' The situation in the late 1990s is much more complex, as some contact with primary schooling, nonformal education programs, and the mass media is now made by the vast majority of families in the Third World. Thus, even though parents may be illiterate, it is not unusual for one or more of their children to be able to read and write to some degree. For this reason, it would seem that simple dichotomies—still in use by some international agencies and most national governments—ought to be avoided, since they tend to misrepresent the range or continuum of literacy abilities that are common to most contemporary societies.

As noted earlier, work on adult literacy has frequently derived its methodologies from the study of reading development in children. This is true of assessment as well, where the diagnosis of individual reading difficulties has held sway for many years, in both children and adults. This diagnostic model of assessment assumes that individuals who do not read well have some type of cognitive deficit which can (often) be remediated if properly diagnosed by a skilled professional. There is little doubt that this model does apply to many adults who have not learned to read, but who have attended school. However, the majority of the world's population of low literates and illiterates (located primarily in developing countries) have received little or no schooling, making the diagnostic method far less relevant. For this latter population, detailed diagnostic measures are unimportant relative to the need for better understanding of who goes to school, what is learned, and which particular social groups are most in need of basic skills. In such cases, as discussed below, low-cost household surveys may be a better assessment technique than diagnostic instruments.

Most countries have formulated an explicit language policy which states which language or languages have official status. Often, the decision on national or official language(s) is based on such

factors as major linguistic groups, colonial or post-colonial history, and the importance of a given language to the concerns of economic development. Official languages are also those commonly used in primary school, though there may be differences between languages used in beginning schooling and those used later on. The use of mother tongue instruction in both primary and adult education remains a topic of continuing debate (Dutcher 1982, Hornberger 1999). While there is usually general agreement that official language(s) ought to be assessed in a literacy survey, there may be disagreement over the assessment of literacy in nonofficial languages (where these have a recognized and functional orthography). In many countries, there exists numerous local languages which have varying status with respect to the official language; how these languages and literacies are included in such surveys is a matter of debate. For example, in certain predominantly Muslim countries in sub-Saharan Africa (e.g., Senegal or Ghana), the official language of literacy might be French or English, while Arabic—which is taught in Islamic schools and used by a sizable population for certain everyday and religious tasks—is usually excluded from official literacy censuses. Many specialists now agree that most (if not all) literacies should be surveyed; to ignore such abilities is to underestimate national human resources.

Comparability of data—across time and countries—is a major concern for planning agencies. If definitions, categories, and classifications vary, it becomes difficult if not impossible to compare data collected from different surveys. On the other hand, if comparability is the primary goal, with little attention to the validity of the definitions, categories, and classifications for the sample population, then the data become virtually meaningless. International and national needs, definitions, and research strategies may or may not come into conflict over the issue of comparability, depending on the particular problem addressed. For example, international agencies continue to utilize literacy rates that are measured in terms of the number of 'literates' and 'illiterates.' For most countries, this type of classification presents few problems at the level of census information, and it provides international agencies with a cross-national framework for considering literacy by geographic or economic regions of the world. On the other hand, national planners may want to know the effects of completion of certain grades of primary or secondary school, or of a literacy campaign, on levels of literacy attainment, so that a simple dichotomy would be insufficient. Household literacy surveys, because more time may be devoted to in-depth questioning, offer the opportunity to provide a much more detailed picture of literacy and its demographic correlates than has been previously available.

2.2 Household Literacy Surveys

Assessment surveys have employed varying approaches to defining literacy skill levels in different countries. For example, some assessment surveys have focused on 'ability to read aloud' from a newspaper in the national language; some have included basic arithmetic (numeracy) skills; while still others have focused on being able to write one's name or read a bus schedule. Two main types of literacy survey methods—self-assessment and direct measurement—have been utilized within widely differing contexts.

Most national literacy data collections in the world have utilized self-assessment techniques, which are operationalized by simply asking the individual one or more questions of the sort: 'Can you read and write?' Occasionally, census takers collect information on which language or languages pertain to the above question, but rarely have time or resources been invested beyond this point. Analysis of the relationship between self-assessment and direct measurement of literacy abilities has rarely been sought, so that the reliability of self-assessment methods is very problematic (Lavy et al. 1995).

Direct measurement of literacy typically involves tests which are constructed with the aim of obtaining performance or behavioral criteria for determining literacy and/or numeracy abilities in the individual. The large number and variety of literacy and numeracy assessment instruments precludes a complete discussion in this brief review. Objective measures rely primarily on test items to elicit valid and reliable data from the individual, with rather strict controls on the context and structure of the test. An example would be a multiple choice test where the individual is presented with a short paragraph of text and is asked to choose, among four items, the item which best describes some particular piece of information mentioned in the paragraph. These measures are usually quite reliable in school settings and for silent reading, where test–retest correlations and cross-test correlations may be highly significant. Their use in nonschool settings and with low-literate adults is less well known, since these tests assume a certain equivalence in 'test-taking skill' across individuals tested. Such objective tests are particularly useful in settings where the interviewer has little prior experience in literacy assessment, since relatively little subjective interpretation of test performance is required.

The direct measurement of literacy skills using assessment instruments provides information on more refined categories than available in self-assessment, which usually provides merely a dichotomous categorization. In industrialized countries, there have been a number of important household literacy surveys. The first two were completed in North America: the Young Adult Literacy Assessment (Kirsch and Jungeblut 1986) in the US, and the

Canadian Literacy Survey (Statistics Canada 1988) in Canada. More recently, a major international survey was conducted in about a dozen OECD countries (OECD/Statistics Canada), using a methodology that overlapped rather substantially with the North American surveys, providing in depth individual assessments of reading, writing, and math skills in both abstract and functional contexts (Tuijnman et al. 1997). While the advantage of such in-depth information may be justifiable in the context of industrialized countries, these surveys clearly represent the 'high end' of both detailed analysis and cost in terms of household surveys.

For contexts such as in developing countries or in low-literate ethnic communities in industrialized countries, it may be useful to choose a categorical breakdown which would provide just enough information for use by policymakers, and which could be more easily and simply constructed. This 'low-end' method of assessment is best exemplified in the model developed under the auspices of the United Nations National Household Survey Capability Program, and which has been undertaken in several countries, including Zimbabwe and Morocco (United Nations 1989, Wagner 1990). In this model, there are four main skill classifications which are proposed: (a) *non-literate* for a person who cannot read a text with understanding and write a short text in a significant national language, and who cannot recognize words on signs and documents in everyday contexts, and cannot perform such specific tasks as signing their name or recognizing the meaning of public signs; (b) *low-literate* for a person who cannot read a text with understanding and write a short text in a significant national language, but who can recognize words on signs and documents in everyday contexts, and can perform such specific tasks as signing their name or recognizing the meaning of public signs; (c) *moderate-literate* for a person who can, with some difficulty (i.e., makes numerous errors), read a text with understanding and write a short text in a significant national language; and (d) *high-literate* for a person who can, with little difficulty (i.e., makes few errors), read a text with understanding and write a short text in a significant national language. When these four categories are utilized in conjunction with other variables in the survey, it becomes possible to arrive at answers to questions often posed by policymakers, such as: How does literacy vary by age, grade, geographical region, language group, and so forth?

2.3 Measuring Literacy Levels

Beyond the broad category labels of literacy levels, there is little agreement on how actually to assign such labels to individuals. Does scoring above 50 percent on a test of paragraph comprehension qualify an individual as literate, nonliterate, or in-between? To a great extent, such labeling has been and

continues to be arbitrary. In addition, while most assessment instruments utilize school-based and curriculum-based materials, there is increasing awareness among specialists of the importance of measuring 'everyday' or practical literacy abilities. One method for dealing with literacy assessment is to determine the intersection of both literacy *skills* and *domains* of literacy practice (Tuijnman et al. 1997).

There are a great many types of literacy tests, and a great number of skills which specialists have thought were important not only for the measurement of actual literacy ability, but also in terms of the underlying processes involved in being a competent reader or writer. Drawing on recent survey work, as described above, it is useful to think of literacy ability as involving at least four basic types of skills: decoding, comprehension, locating information, and writing.

Individuals who use literacy may perform literate functions on a wide array of materials; in addition, certain individuals may specialize in specific types of literate domains (e.g., lawyers, doctors, agricultural agents). Even individuals with low general levels of literacy skill may be able to cope successfully with written materials in a domain in which they have a great deal of practice (e.g., farm workers who often deal with insecticides). Since governments are generally interested in providing literacy for many categories of people, an assessment should sample across the material domains where literate functions are typically found, such as, single words, short phrases, tables and forms, and texts.

The estimation of literacy skills by text domains involves the use of a matrix of the intersection of literacy skills with the text domains in which literacy skills can be applied. This provides a breakdown of types of component skills in literacy. It should be understood that there is rarely consensus on which specific skills to test in literacy, and that any such matrix is necessarily arbitrary. Nonetheless, a matrix of literacy skills by domain can provide a useful method for collecting the appropriate ('low-end') amount of information needed for policy decisions, and it can be considerably less expensive than some of the comprehensive methods employed in the North American surveys.

3. Literacy Research and Innovation

Based on the growing concern about literacy levels across the globe, it seems clear that new domains of research will begin to open up, such as the topics described below.

3.1 Technology

There are new and exciting ideas about the utility of technology for literacy provision to children and adults. Much of this work is still in the early development stages, such as efforts to utilize synthetic speech to teach reading, or the use of multimedia

791

displays (interactive video, audio tapes, and computer displays) to provide more sophisticated instruction than has been heretofore available. Technological solutions to instruction—known as computer-based education (CBE) or computer-assisted instruction (CAI)—have been used, primarily in industrialized nations, since the early 1980s, and the presence of microcomputers in the classrooms of schools has continued to grow at a phenomenal rate, especially with the advent of the Internet (Anderson 1999, OECD 2000, Wagner and Hopey 1999).

Until the 1990s, the cost of educational technology was too high even for most industrial countries, and therefore far beyond the means of the developing countries. But the price-to-power ratio (the relative cost, for example, of a unit of computer memory or the speed of processing) continues to drop at an astounding rate. While the cost of the average microcomputer has remained constant or declined slightly for about a decade, the power of the year 2000 computer is 10–100 times greater than that produced in 1990. If present trends continue, the capabilities for CAI and CBE literacy instruction are likely, by the year 2010, to go far beyond the elementary approaches of the 1990s.

3.2 Multisectoral Approaches

Literacy skills are utilized in many life contexts outside of academic settings. To date, most research and development has focused primarily on school-based settings. A major challenge rests in determining the ways that literacy can be fostered and utilized in everyday family and work settings. From a policy perspective, more needs to be known about how literacy education can be infused into the significant development work of other sectors, such as agriculture and health. In these two sectors, literacy is a major vehicle for innovation and knowledge dissemination, yet few studies have explored what levels of literacy determine the effectiveness of such dissemination.

3.3 Design of Materials

In developing countries, increased textbook provision has been viewed by donors and ministries of education as a key strategy for the improvement of school instruction (Heyneman and Jamison 1980). However, very little is known about how the design of instructional materials influences comprehension and learning. There are also enormous subject matter and national variations in conventions of text design. Some important work on the relationship between characteristics of textbook discourse and comprehension is being carried out that has implications for improving school textbooks, as well as materials for other sectors. For example, there is a special need to improve instructions for pharmaceutical and agricultural chemicals, whose safe and effective use requires performing complex cognitive tasks with procedural

information that is often difficult to comprehend (Eisemon 1988, Wright 1999).

3.4 Mother-tongue and Second-language Issues

As previously discussed many learners enrolled in adult education programs are being taught literacy in a second language. In developing countries, a significant proportion of these students are either illiterate in their mother tongue or receive only a few years of mother-tongue instruction before a second, usually foreign, language is introduced as a medium of instruction. Poor second-language literacy proficiency is a cause of high repetition and wastage rates, and of low achievement in academic subjects in primary and secondary schools with profound consequences for employment and other externalities of schooling.

Because of the significant debate on first- and second-language/literacy policy (often related to national issues of ethnicity and power), most government agencies worldwide have been reluctant to review such policies. However, there are a number of important areas of work which need to be addressed beyond the confines of this debate, such as: (a) Under what conditions should mother tongue literacy be a precondition for the introduction of second-language literacy in school-based and non-formal settings? (b) How does the implementation of language-of-instruction policies affect literacy after schooling? (c) What are the effects of using second-language literacy in school on wastage and grade repetition? (d) What are the implications of using the second-language literacy for academic subjects like mathematics, science, health, nutrition, and agriculture? (e) What roles do orthographic similarity and dissimilarity play in transfer between mother tongue and second literacy? These and similar questions will need to be addressed before major progress can be made in improving literacy levels in national and international contexts.

4. Conclusion

The importance of research, measurement, and innovation in literacy is that they can provide new paths to greater efficiency in literacy provision around the world. While no social program (including research) is without economic costs, such expenditures must be understood in the light of costs involved in not knowing how to carry out literacy programs practically and efficiently. Those who have argued that the literacy crisis is so great that the support of research is somehow wasteful are likely to be proven wrong. To invest resources in implementation without developing the means to learn from such programs is to call into question any purported gains in literacy work.

The year 2000 was a critical moment to reinforce literacy efforts, as global economic changes are requiring significant changes in worker skills and the

heightened role of information exchange. In spite of the clear need for cultural sensitivities and specificities, there may be important economies of scale as more is learned about literacy. Methodologies for pilot programs, assessment and evaluation, and computerized textbook preparation, as examples, may be transferable with local adaptations to varying cultural contexts. The need for literacy and other basic skills has never been greater, and the gap between literate and nonliterate lifestyles is becoming ever larger, with parallel growth in income disparities. Literacy and learning are a part of the culture of every society. To produce major changes in literacy requires both a realistic understanding of the kinds of change which people and nations desire, and sustained support to provide appropriate instructional services.

Multidimensional Scaling
W. C. Rau

Graphic models have a long history in the study of language; the century-old, frequent use of tree diagrams to represent syntax and grammar stands as an eloquent testimony to the need for classificatory

tools in language studies (Stewart 1976). Linguists seem much more reluctant, however, to use conventional statistics in their investigations, and texts on statistical applications in linguistics (e.g., Butler 1985) seem rather elementary from the perspective of the social sciences. There are exceptions, of course, with the work of Labov (1980) and Osgood (1975) coming immediately to mind. Nonetheless, one looks long and hard through mainstream journals, such as *Language*, to find the kind of empirical and statistical analysis that a social scientist would recognize. Data do not appear very often, but when they do, they may be presented without further statistical analysis or interpretation (e.g., Lipski 1986, Lehrer 1985). This is unfortunate, because many new statistical tools exist that can profitably analyze a broad range of linguistic phenomena. One such technique is multidimensional scaling (or MDS). Linguists will be relieved to see that it presents their data in sheer attire, accentuating rather than concealing what is already there.

1. Basic Procedures

As a preparatory step for analysis, social scientists gather information into a data matrix where observations are placed in the rows, and variables are placed in the columns. For example, Cavalli-Sforza and Wang (1986) analyzed linguistic data from Micronesia that filled a data matrix containing fully 9,136 pieces of information. Imagine their matrix drawn on a very wide sheet of paper. There are 16 rows of data, one for each island's linguistic data. Each of the 571 columns represents a particular gloss or word. Each of the 9,136 cells of this vast table contains the morpheme employed by the particular society (row of the table) for the particular word (column of the table). For example, a full stomach is described as *mat* on the island of Tobi, *math* on Falalop and Mogmog, and *mät* on Woleai, Ifaluk and Satawal. Societies with the same morphemes have cell entries of 1; those with different morphemes receive a zero.

This array of information is referred to as raw data. The point of statistical analysis is to 'boil down' or 'reduce' these raw data to a set of summary indices or dimensions which can then be used to highlight major patterns in the data. One of the more common first steps in this process of reduction is for the analyst to calculate some measure of association among either the variables or observations in the matrix. Pearson's or Spearman's correlation coefficients, one of the numerous matching coefficients, or a distance measure, such as Euclidean distances, represent some of the choices. These measures are then reduced further through use of factor analysis, multidimensional scaling, or regression analysis. When well done, the end result is a parsimonious rendering of the major patterns of association among variables or observations in the original data matrix.

The first step in this process leaves one with a triangular matrix, such as the upper-right triangle in Fig. 1. This table is a small excerpt of the one published by Cavalli-Sforza and Wang, and shows relationships linking only 6 of the 16 islands. Each element in the matrix shows the extent to which one observation (or variable) is similar to or different from another observation (or variable). In Fig. 1 Woleai and Mogmog show the highest correlation, 0.728, and Satawan and Tobi the lowest, 0.446. In the full data matrix, the highest coefficient found, 0.987, is for Falalop and Mogmog, and shows these islands to have nearly all of the 571 linguistic characteristics in common. Tobi and Murilo, however, have the lowest coefficient, 0.406, with less than half the characteristics in common.

Reducing a data matrix to a set of similarity measures is straightforward; any of a number of computer statistical packages will reduce even the largest data matrix in a matter of seconds. The real issue is whether to reduce the data matrix across either the variables or the observations. For example, one can reduce the 16×571 Micronesian data matrix to a 571×571 matrix of correlations among variables (words) or a 16×16 matrix of correlations among observations (islands). Which way does the linguist want to go?

Here, conventional practices in the social sciences are not helpful. Most social scientists are interested in testing hypotheses which, with nearly universal regularity, are couched in the language of variables. Proverbial Variable X is hypothesized to affect Variable Y, so the analyst uses correlation analysis, regression analysis, etc., to determine how changes in

			Miles/Matching coefficient			
	Tobi	Mogmog	Woleai	Satawal	Puluwat	Satawan
Tobi	—	0.643	0.588	0.507	0.466	0.446
Mogmog	667	—	0.728	0.604	0.543	0.507
Woleai	809	298	—	0.716	0.601	0.526
Satawal	987	464	186	—	0.692	0.562
Puluwat	1,112	585	314	129	—	0.657
Satawan	1,360	880	597	417	296	—

Figure 1. Geographical distances and matching coefficients among six Caroline Islands and languages.

Variable X or a set of X Variables is associated with change in Variable Y. In short, social scientists almost always work across the columns in the data matrix.

Linguists would appear to be more interested in patterns among observations. Linguistic analysis is more holistic or relational than most quantitative analysis in the social sciences (cf. Rau and Roncek 1987, Rau and Leonard 1990). If true, then linguists should reduce data across the rows of the data matrix and not across the columns. This crucial difference may be one reason why linguists have been reluctant to borrow statistical tools employed by social scientists. The latter, with their excessive fixation on conventional approaches to hypothesis testing, use statistical tools almost exclusively to analyze variables. Hence, the manner in which some of these tools can be adapted to the analysis of linguistic data has not been clearly demonstrated. It will now be shown below how MDS can assist in holistic analyses of data by reducing measures of association among observations.

2. An Application of the Method

One cannot imagine a better or more parsimonious theory for demonstrating this use of MDS than that provided by Cavalli-Sforza and Wang (1986) in their study of lexical replacement in the Carolines, a chain of islands and atolls in Micronesia. Directly north of New Guinea and the Solomons, to the east of the Philippines, and to the west of the Marshall Islands, the 16 islands and atolls in their study stretch in a ragged but compact band for some 1,400 miles. The Carolines represent an ideal natural laboratory for testing their 'stepping-stone' theory of language change.

In a simplified version of the wave theory of language change, they argue that linguistic diffusion will be a negative exponential function of the distance separating a linear array of discrete language communities. Linguistic diffusion in traditional wave theory is complicated by the multidirectionality of sources of linguistic innovation. Since change can emanate from a number of different directions, a complex network of isoglosses can result. Choice of the Carolines minimizes the problem of multidirectionality since, as noted, the islands are somewhat isolated and spread out in a fairly straight and narrow band. Given these fortuitous geographic circumstances, one can expect linguistic differences among the islands to be a function of their respective geographic distances.

2.1 Creating a Map of the Carolines

The measures published by Cavalli-Sforza and Wang (and excerpted in Fig. 1) can be used to explain the principles in MDS and then to provide a new test of stepping stone theory. First, the miles between pairs of islands are scaled, as given in the lower left triangle in Fig. 1. MDS can scale distances as well as correlations or matching coefficients. Several classic demonstrations of MDS principles produce maps from a matrix of distances among cities (see Kruskal and Wish 1978: 7–10, Borg and Lingoes 1987: 1–5). MDS can produce an accurate map if it is given the miles or kilometers between any number of locations, be they cities or atolls. A map of the Carolines is seen in Fig. 2, with the names of the atolls placed as close as possible to their point locations. It was generated with ALSCAL (Alternating Least Squares Algorithm for Scaling), an MDS algorithm developed by Forrest Young and others (Young 1987, Young and Lewyckyj 1979) and carried by such popular computer statistical packages as SPSS and SAS.

Notice one interesting feature of the plot. When any of the MDS algorithms produces a configuration, the 'compass points' or termini of the resulting coordinates are arbitrary. In the present case, the configuration in Fig. 1 represents a mirror inversion of how the Carolines are presented in a geographic atlas. What is most important in multidimensional scaling is the structure or pattern of relationships among objects in the configuration. Whether the objects come out upside down is completely irrelevant. The researcher can always stand on his head—or simply give the configuration a spin so that it conforms to the conventional, and arbitrary, Eurocentric geographical coordinates. Australians, for example, might find the present configuration entirely sensible!

2.2 The MDS Algorithms

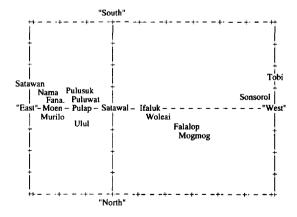
Before getting into substantive issues, it will be useful to explore briefly how MDS algorithms produce configurations. For purposes of illustration the


Figure 2. ALSCAL plot of the Carolina configuration.

strategy behind Smallest Space Analysis will be demonstrated. This is an MDS algorithm developed by Louis Guttman (1968) and James Lingoes (1973). Smallest Space Analysis is a close cousin to ALSCAL, and its principles are easier to illustrate.

The lower left triangle of the first matrix in Fig. 3 contains the miles separating six islands, simply copied from Fig. 1. MDS starts with comparisons among each pair of islands, 15 island-pairs in this case. It begins by assigning a ranking number of each pair; the islands separated by the smallest distance are assigned as 1, the pair with the next smallest distance a 2, and so on until 15 numbers are assigned. The D Matrix in Fig. 2 gives the resulting integers for the island-pairs; it gives the rank order structure of distances among the six islands. It shows which islands are closest and furthest away from each other in space. Puluwat and Satawal, separated by a distance of only 129 miles, are ranked at 1; Tobi and Satawan, with 1,284 miles between them, get the rank of 15.

MDS will now produce a configuration of points which tries to reproduce the D Matrix ranking integers within the space or dimensionality specified by the researcher. Since stepping-stone theory assumes a one-dimensional array of language communities, that constraint is applied even though locations in geographic space usually require two or three dimensions for a completely accurate mapping. In the present instance, MDS has the added advantage of testing whether the Carolines approximate the unidimensional ordering assumed in stepping-stone theory. If distances among these islands are in fact sequences in an order approximating a line of stepping-stones, then MDS will be able to fit them onto a one-dimensional line.

Smallest space analysis begins with a principal components solution. Each island gets a numeric value giving its location as a point on the principal components dimension. These values are then used to calculate interpoint distances across each pair of islands. Next, these distances are transformed into 'rank images' and stored in a D* Matrix. Corresponding ranks in the two matrices are compared, and then points in the configuration are shifted about until the rank images in the D* Matrix correspond as closely as possible to the ranking of integers in the D Matrix. This iterative process is guided by a 'badness of fit' measure, called the 'coefficient of alienation' in Smallest Space Analysis (and 'stress' in ALSCAL), which optimizes the fit between the rank images and ranking integers. When and if the coefficient of alienation equals 0, then the rank images and ranking integers correspond perfectly. In the present instance, this would mean that the six islands can be sequenced into a one-dimensional array with no loss of the rank ordering of the mileage in the original distance matrix.

In Smallest Space Analysis, the loss function or coefficient of alienation is given by

$$u = \Sigma d_{ij} d_{ij}^* / \Sigma d_{ij}^2 \qquad (1)$$

$$K = (1 - u)^{1/2} \qquad (2)$$

The term d_{ij} is the rank ordering of the distance between the ith and jth islands in the D Matrix, and d_{ij}^* is the rank image for the same island-pair. K is the value of the loss function or the coefficient of alienation. On the basis of a hand-estimated point plot of a smallest space configuration in Fig. 3, $K = 0.06$, which means that the six islands can be sequenced in a one-space with almost no loss of the information in the original distance matrix.

Computers do it better, and in this case ALSCAL can fit the 16 islands and 120 island-pairs in one dimension with a stress value of 0.024, thus accounting for over 99 percent of the rank order information in the original distance matrix. While stress in two dimensions is zero, the islands are pretty much in a straight line, thus permitting only one dimension to be used. In short, the Carolines do present an ideal natural laboratory for Cavalli-Sforza and Wang.

Equally comforting is the fit of the matching coefficients presented in the matrix for all 16 islands. As noted, MDS algorithms can also fit similarity coefficients which transform binary data into measures ranging from 0 to 1.00. Since many kinds of linguistic data can be represented in binary form (+, −; yes, no; present, absent), transformation of this information into a matrix of matching coefficients prepares them for MDS analysis. For these matching coefficients, the stress value in one dimension is 0.065; hence 98.7 percent of the information in the coefficient matrix is preserved in a one-dimensional array of the islands.

2.3 Testing Stepping-stone Theory

The stepping-stone theory can now be tested in a simple and direct fashion. The MDS configurations allow the islands to be sequenced into geographical and lexical arrays. If the theory is correct, the position of the 16 islands in the two arrays should be the same, or at least very close. This is in fact the case. From one end, the geographic array begins: Tobi, Sonsorol, Mogwog, Falalop, and Woleai. The lexical array is almost identical, beginning: Tobi, Sonsorol, Falalop, Mogwog, and Woleai. Ten of the 16 islands have exactly the same rank order linguistically as they do geographically, and the rest average only about two ranking steps different in the two arrays. The correlation between the ordering of the linguistic and geographic arrays is 0.926, which is very nice indeed.

One always expects data to depart to some degree from the pure pattern predicted by a theory. In this

Island	Tobi	Mogmog	Woleai	Satawal	Puluwat	Satawan	
			Miles\Rank order

Figure 3. An illustration of the MDS fitting process.

case, islands that are but a stone's throw away from each other may have reversed orders, such as Mogwog and Falalop. In addition, Fig. 2 shows islands in the Truk District (The Eastern Carolines) to have as much longitudinal displacement as latitudinal displacement. And the positions of Murilo and Satawan differ five and four steps, respectively, in the linguistic and geographic rankings. Such deviations should come as no surprise. Among the great maritime navigators in premodern times, Micronesians could transverse the distances among islands in the Truk District (Gladwin 1970, Lewis 1972). Different population sizes and rates of trading and exchange could account for these minor deviations.

3. Pronunciation in Dialects of Spanish

Another area for which MDS is suited concerns the study of dialects. This area already has lent itself to imaginative map making. Maps such as those made by Dennis Preston (1986) require a rather direct correspondence between geographic regions and systems of pronunciation, however, and the distribution of dialects does not always prove so convenient. Spanish is a case in point. Moreover, the nature and distribution of Spanish dialects is a major educational issue as well. In the USA, Anglo students are taught in the dialect of Mexican Spanish, and they assume that since it is taught in the schools it must therefore be the 'standard' or 'correct' pronunciation. When students have difficulty understanding Cubans or Puerto Ricans, for example, they often assume 'that Puerto Rican and Cuban pronunciation is somehow sub-standard or inferior, and therefore the lack of comprehension is the fault of the native speakers themselves and not the students or the school system' (Terrell 1977: 35).

How then does Mexican or so-called 'standard Latin–American pronunciation' compare with other dialects? MDS can show this by plotting a *figurative* map giving the similarities and differences among any number of dialects. One of the raw data matrices mentioned earlier will illustrate this, a compilation of the field work of John Lipski and others (Lipski 1986). The original data matrix presents different ways of pronouncing the phoneme /s/ in seven cities or areas in Spain and another 21 cities or countries in Central and South America. It appears that in most of these studies 10 respondents with a high school education (typically from capital or major cities) were interviewed for one half hour in an informal or conversational style. Tape recordings were then analyzed for the frequency of occurrence of different ways of pronouncing /s/ in five different spoken contexts, such as immediately after another consonant or after a word break and a stressed vowel. Three different pronunciations of /s/ were noted: simple sibilant, aspiration, or deletion.

3.1 Analyzing the Spanish Data

Considering just /s/ after a consonant, three cities can be compared to note the kinds of differences present in the dataset. In Barcelona, Spain, 99 percent of the time a simple sibilant was spoken, and 1 percent of the time an aspiration was given instead. The percentages were very similar in Madrid, 94 and 6 percent. But in Granada, a sibilant was never spoken, while 82 percent of the time there was an aspiration, and in the remaining 18 percent the sound was deleted altogether. Clearly, Barcelona and Madrid are similar, while Granada is quite different from both of them. It is easy to quantify this difference. To determine the linguistic 'distance' between two cities, the Euclidean distance formula will be used to total the differences between the percentage figures for all the language characteristics in the data set.

These data have been transformed into a matrix of Euclidean distances among the pairs of countries or cities. Two cities with the same patterns of pronunciation would have a distance of 0. They would have the same frequency or percentage of occurrence for the 15 variables represented as columns in the data matrix. As distances between pairs increase, they become less and less similar. MDS can reveal both the range and variety of differences contained in a matrix. Put differently, it can reveal both quantitative and 'qualitative' differences. But first the number of dimensions needed for an accurate point configuration must be determined.

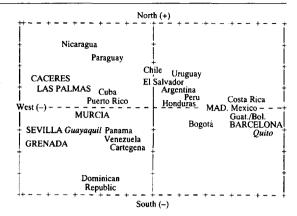
The ALSCAL stress values for three through one dimensional solutions are as follows. A three-dimensional solution has a stress of 0.042, a very small departure from a perfect fit, while a two-dimensional solution does almost as well, with a stress of 0.068. A one-dimensional solution is markedly worse, at


Figure 4. ALSCAL configuration for Spanish dialects.

0.206. Another way to evaluate the solutions is in terms of R^2, the 'variance explained,' a measure of how well the solution captures the information in the data matrix. R^2 for three dimensions is 0.991, almost the theoretical maximum of 1. But a two-dimensional solution is not far behind, with an R^2 of 0.980, while one dimension explains considerably less of the variance, with 0.871. Clearly, a two-dimensional solution is nearly as good as a three-dimensional one, and far better than a one-dimensional solution, almost completely reproducing the information in the original matrix. And two dimensions are easier to visualize than three. Therefore, two dimensions can provide our figurative map of similarities and differences among Spanish pronunciations.

Figure 4 is the resulting map. Compare the locations of Mexico, Cuba, and Puerto Rico. Their distance apart brings out the difference in their phonological systems. Mexican pronunciation is most similar to the Spanish spoken in the six to seven countries directly adjacent to it at the center east end of the plot. By the same token, Mexican Spanish is hardly the hub of Lipski's sample of dialects. If, for the moment, the seven dialects clustered around Mexico are ignored, then Cuba and Puerto Rico, along with Murcia become the hub or center for the remaining 17 dialects.

Note also, as in the case of Spain, the diversity of pronunciations that can occur within a country. The Spanish spoken in Madrid (MAD in the plot) is most similar to that spoken in Mexico and very similar to that of Barcelona, but it is clearly not representative of the other areas in Spain. Those areas, which are capitalized in Fig. 4, form a sideways V at the west end of the plot. Although Madrid and Mexican Spanish and highly similar, Murcian Spanish is more similar to the other dialects in Spain. With regard to the phoneme /s/, someone from Murcia would pronounce words very much like a Cuban or Puerto Rican, and not at all like someone from Madrid or

Barcelona. To the extent that the first coordinate (the east–west axis) is more important than the second (the north–south axis), then there is more dialect diversity within Spain proper than in the Latin American areas featured in Lipski's sample. Sampling of a number of sites within each of the other countries might increase the overall diversity, however. As a case in point note the difference between Guayaquil and Quito in Ecuador—and to a lesser extent, the differences between Bogotá and Cartagena in Colombia.

3.2 Interpretation of an MDS Map

This brings up the issue of interpreting the properties of dialect clusters or regions in Fig. 4. Two interrelated strategies can help to determine why one group of observations locate in one region of the configuration, and other groups of observations locate elsewhere. More generally, these strategies identify the properties of each of the dimensions framing a configuration. Figure 4 has two dimensions. What aspects of the data, then, are responsible for observations locating at either the east or west end of dimension 1, or the north or south end of dimension 2? Clearly, this is not a simple case of diffusion like that illustrated by the Micronesian data considered above, because there is little correspondence between the linguistic map in Fig. 4 and the geographic positions of the observations. The configuration must be understood in some other way.

One simple and direct approach is to choose a set of observations which extend across one dimension while varying little on the other dimensions. The analyst then inspects the data matrix and finds those variables which change in the most consistent and dramatic fashion as one moves along the dimension. For example, as one scans along dimension 1 from Barcelona through Bogotá, Panama, and Guayaquil to Sevilla, the data reveal a great decrease in the use of sibilants. But picking a route through the observations is a bit subjective. Also, especially when the data set contains a great variety of variables, it can be difficult to decide which variables are most responsible for the configuration.

A second approach is to use regression analysis (Kruskal and Wish 1978) to establish the relationship between the variables in the raw data matrix and numerical scores for the dimensions in the MDS solution. For Lipski's data, the 28 observations have numerical scores on each of the 15 variables in the raw data matrix plus another score on each of the dimensions or coordinates in the MDS configuration. Each of the 15 variables can simply be regressed onto the values for the two dimensions. Variables with the largest regression weights for a particular dimension are the ones that will change in the most consistent and dramatic fashion for observations located at different points along the projection

of that dimension. Thus, these two strategies are complementary.

The results for the regression strategy are in Fig. 5. The decimal values under each dimension are standardized regression weights or betas. The betas for each row establish the relative contribution that scores for each dimension make to the variance explained for a variable. The R^2 value gives the total variance explained by both dimensions. For example, the two dimensions account for 87 percent of the total variance in the first variable (sibilated consonants), and dimension 1, with a beta of $+0.93$, is responsible for nearly all of this variance. As a matter of convention, ALSCAL assigns positive numeric values to dimension scores to the east and north of the center of a configuration; dimension scores to the west and south are negative. Thus, the positive sign for this beta means that the percentage of sibilated consonants increases as one moves from west to east on the first dimension. More generally, the beta weights are roughly analogous to factor loadings in factor analysis (for a discussion of factor analysis see Rummel 1970). They tell us which variables are associated with which dimensions.

The results in Fig. 5 present the kind of distinctive statistical attire that reveals that stately beauty of human language. The clarity and strength of the patterns are striking and are reminiscent of Einstein's famous adage: if God does not play dice with the universe, then the Spanish certainly do not play dice with their dialects. In this table Lipski's variables have been rearranged to bring out the numerical expression of the rules of pronunciation contained in his data. If /s/ is rendered as a sibilant after a

	Variable	Dimension		R^2
		1	2	
Simple Sibilant [s]				
1	Consonant	0.93	−0.06	0.87
4	WB Consonant	0.90	−0.13	0.82
7	Before Pause	0.91	0.18	0.87
10	WB Stressed Vowel	0.84	−0.02	0.71
13	WB Unstressed Vowel	0.93	0.08	0.88
Aspiration [h]				
2	Consonant	−0.82	0.40	0.83
5	WB Consonant	−0.74	−0.55	0.85
8	Before Pause	−0.32	0.53	0.39
11	WB Stressed Vowel	−0.60	0.54	0.66
14	WB Unstressed Vowel	−0.82	0.32	0.78
Deleted [0]				
3	Consonant	−0.44	−0.65	0.62
6	WB Consonant	−0.43	−0.61	0.56
9	Before Pause	−0.81	−0.38	0.79
13	WB Stressed Vowel	−0.58	−0.54	0.64
15	WB Unstressed Vowel	−0.69	−0.65	0.89

Symbol: WB = Word Break

Figure 5. Standardized regression coefficients of ALSCAL dimensions for each phonetic variable.

consonant, then it is also rendered as a sibilant after stressed or unstressed vowels and pauses or word boundaries. To a lesser but still striking degree, the same rule holds for aspiration or deletion.

Next, the results in Fig. 5 can be used to help identify the phonological differences responsible for the dispersion of the 28 dialects into different regions and clusters in the two-dimensional configuration. The regression weights for dimension 1 show that speakers at the east end of the configuration pronounce /s/ as a sibilant; those at the west end resort to either aspiration or deletion. We can distinguish further aspiration from deletion by means of dimension 2. Those at the north end of coordinate 2 rely on aspiration, those at the south end, on deletion.

4. Scaling Individual Speakers

One more example may prove useful. Thus far, aggregated data, i.e., islands and cities have been analyzed. MDS can be just as useful in analyzing patterns among individuals, although loss functions may run higher. For purposes of illustration, the individual-level data provided by Mohan and Zador (1986) are examined.

These researchers were interested in the process of 'language death' (see *Endangered Languages*) which they characterize as the point at which an ethnic community loses the ability to speak in its native language. A major question is whether language death is a slow, gradual process akin to Darwinian evolutionary change, or whether it is marked by sharp discontinuities among groups of speakers who possess qualitatively different degrees of fluency in the ethnic language. Mohan and Zador chose the (South Asian) Indian community in rural Trinidad, West Indies, for study of this issue. Beginning in the mid-nineteenth century, the area received migrants from Uttar Pradesh and western Bihar who worked as indentured laborers on sugar plantations. Once the common language of the Indian community, Trinidad Bhojpuri is now only spoken frequently by older, rural inhabitants of the island. Creole and Standard English have become the languages of choice among Indians born in Trinidad.

To determine the nature of language change in this community, Mohan and Zador tested the language competence of 40 speakers of Trinidad Bhojpuri who were grouped into four age categories. Speakers' ages ranged from 26 to 96, but the key group consisted of speakers under age 35. While the older subjects were representative of their age groups, Mohan and Zador were hard pressed to find younger subjects who were capable of speaking Trinidad Bhojpuri for any length of time. Subjects number 31 through 40, all under age 35, were thus chosen on an *ad hoc* basis. Eight of these respondents consisted of sibling pairs who were close in age.

Mohan and Zador then tape recorded half-hour segments of speech in Trinidad Bhojpuri and calculated the average speed of speech, five different kinds of errors, and ten incidence counts of features of Trinidad Bhojpuri that a fluent native speaker would possess. Taken as a whole, their 16 measures were designed to elicit the kind of speech—fast, correct, and articulate—that competent speakers of any language will possess. If the loss of a native language is a gradual process, then a gradual loss of speed and grammatical complexity and a gradual increase in errors would be expected. On the other hand, if there is a relatively discontinuous loss of language, a qualitative break in performance across these measures could be expected.

The MDS analysis of the structure of relations among observations is ideally suited to test issues of this sort. If major discontinuities exist, an MDS configuration will show large gaps resulting in noncontinuous groups of subjects. The 40×16 matrix was transformed to a matrix of Euclidean distances among the 40 subjects, and then analyzed with ALSCAL A one-dimensional solution had a stress of 0.205 and R^2 of 0.898, not terribly impressive. Solutions with two, three, and four dimensions had stresses of 0.132, 0.098, and 0.071, respectively. There is no hard and fast rule for determining an acceptable stress value, but as a general rule analysts like to get stress below 0.10, although this is not always possible or necessary. In this case, a three-dimensional solution achieves this criterion. Inspection of the plots for both two-dimensional and three-dimensional solutions leads to the same outcome.

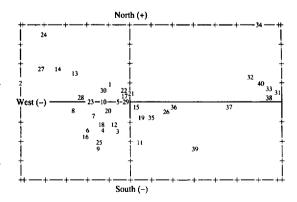
Figure 6 uses the first and second dimensions of a three-dimensional solution, and it reveals the gap expected by advocates of theories of discontinuous language change. Six of the under age 35 group locate at the far east end of the configuration. Only two isolates (speakers 37 and 39), also under 35, occupy a large empty region before one encounters a much larger cluster of competent Trinidad Bhojpuri


Figure 6. Plot of dimensions 1 and 2 for Trinidad Bhojpuri configuration.

speakers in the center west region of the configuration. Only two speakers under age 35 (numbers 35 and 36) are adjacent to this cluster, so the configuration establishes a large, decisive break in the linguistic competence of the older and younger respondents.

The techniques of MDS permit further refinements in this analysis. For one thing, the solution suggests either that some of the variables employed by the researchers measure something other than competence, or that competence itself is not unidimensional. Regression analysis can help us interpret the dimensions. The east–west dimension, not surprisingly, is strongly associated with rapidity of speech, with the slow speakers in the east, and the fast ones in the west. This dimension has some claim on the label of 'general competence,' because most of the 10 features of Trinidad Bhojpuri are associated with the fast-speaking west end of the configuration, and most of the five errors are associated with the east end. However, some of the features are far more strongly associated (conjunctive markers, compound verbs, and noun definitizers) than are others (relative clauses and numerical classifiers). The second dimension is greatly defined by lack of relative clauses, use of numerical classifiers and noun definitizers, and omission of copulas.

A fresh analysis could further differentiate the large cluster of speakers in the center west of Fig. 6, and there is the small group in the northwest to consider as well. Interpretation of the groupings—and definitive interpretation of the dimensions—would require a scholar with the understanding of Trinidad Bhojpuri possessed by Mohan and Zador. The important point is that Fig. 6 identifies some noticeable differences among fluent speakers of Trinidad Bhojpuri, as well as charting the distribution of degrees of competence in this dying language. In short, MDS offers linguists a powerful tool for systematically identifying both large and subtle differences in linguistic competence.

5. Conclusion

Several ways have been shown in which multidimensional scaling of observations can assist linguists in their study of the structure of language. Whether one is concerned with individuals or communities, one period of time or several, MDS can assist in the identification and interpretation of patterns in data. A few linguists, such as Cavalli-Sforza and Wang or Mohan and Zador, already use conventional statistical tools to good effect. The MDS strategy employed here provides additional confirmation for their theories while demonstrating the advantages of complementing conventional statistical tests with results from MDS. Additionally the technique could be of value to linguists who have never used statistical tools, conventional or otherwise.

Observer's Paradox

A. Davies

The term 'observer's paradox' refers to the well-known methodological problem in linguistic research: how to collect samples of authentic casual speech. Labov (1972, see *Labov, William*) presents it thus:

> the aim of linguistic research in the community must be to find out how people talk when they are not being systematically observed; yet we can only obtain these data by systematic observation. The problem is of course not insoluble: we must either find ways of supplementing the formal interviews with other data, or change the structure of the interview situation by one means or another.
>
> (1972: 209)

The term 'observer's paradox' is appropriate because it suggests that the data of speech which the observer wishes to elicit are (or may be—there is no way of knowing) contaminated by the presence of the observer. The methodological problem, therefore, is how to observe without observing. This is of particular relevance to sociolinguistic research, given the importance accorded by Labov to the most casual speech (which he terms 'the vernacular') in determining the direction of language change.

As Preston points out, 'the more aware respondents are that speech is being observed, the less natural their performances will be. The underlying assumption is that self-monitored speech is less casual and that less casual speech is less systematic, and thus less revealing of the ... vernacular' (Preston 1989: 7). Labov's concern with the methodological imperatives of his search places him in the anthropological tradition of participant observation. In that tradition, the anthropologist attempts to share the daily routines of the society s/he is studying as a means of gaining a better understanding and heightening rapport with the people s/he is studying. In private, normally inaccessible, settings, there are well-known techniques, using 'poses' or 'disguises,' for gaining access which might otherwise be denied. Such techniques include posing as a patient in a mental hospital, a prison inmate, or a newspaper reporter.

Labov offers a number of techniques for gaining access to these private speech situations which are normally inaccessible: 'various devices which divert attention away from speech and allow the vernacular to emerge' (1972: 209). The subject, says Labov, may be involved in questions and topics 'which recreate strong emotions he has felt in the past or involve him in other contexts.' The best-known of such questions in the Labov methodology is the 'Danger of Death' question: 'Have you ever been in a situation where you were in danger of being killed? Narratives given in answer to this question almost always show a shift of style away from careful speech towards the vernacular' (Labov 1972: 209–10).

Labov seems uninterested in the ethical questions posed by such techniques, questions which exercise many social science researchers. In addition to the doubtful ethicality of poses and disguises, there is the question of their effect on research validity. Whether or not such techniques as a pose or a disguise, or a misinforming of the subject by pretending to ask about some incident while really being interested in his/her speech, or again a surreptitious recording machine, are ethical, the fundamental philosophical problem of perception remains. This is an enduring problem of philosophy, associated with Bishop Berkeley's '*esse est percipi*' (to be is to be perceived) and with the tradition of phenomenalism, according to which the reality of an external physical object is based on its being perceived by someone.

To such a powerful view there is no logical answer, as Boswell drily comments in his account of Dr Johnson's famous commonsense 'refutation' of Berkeley 'I shall never forget,' writes Boswell, 'the alacrity with which Johnson answered, striking his foot with mighty force against a large stone, till he rebounded from it, "I refute it thus"' (1922: 162).

Labov is indeed correct in referring to the problem as a paradox. In sociolinguistic research, one can never be sure that the observer, however disguised, however familiar, has no influence, and that 'good' vernacular data have been elicited. After all, the only valid vernacular data that can be observed are the observer's own, and phenomenalism's flip side of solipsism ensures that we can never be sure that other people are like us when we are not observing them. Labov's confidence that his techniques do indeed bring about a shift of style towards the vernacular may therefore seem to be *too* certain. No methodology can completely remove the ethical and the philosophical constraints, although one may choose, like Dr Johnson, to suspend disbelief and assume that it does.

Observing and Analyzing Classroom Talk
A. D. Edwards and D. P. G. Westgate

Although talk constitutes such a large part of what goes on in classrooms, its live recording and detailed analysis have only developed since the late 1960s. This article illustrates the wide range of research approaches which are now clustered under the heading of classroom talk. Although the boundaries between them should not be marked too rigidly, there are substantial differences in the comprehensiveness and detail of what is recorded and transcribed. These differences are not a matter of pure versus applied research. They reflect the extent to which the primary interest is in what the patterning of communication reveals about the relationship of teacher and students and the communication of classroom knowledge, and whether and how far the analysis is informed by linguistic theory and shaped by a predominant interest in linguistic structure.

1. Research Traditions

Toward one end of that research continuum, studies using what Stubbs (1983) calls 'insightful observation' seek to heighten practitioners' awareness of the scope and quality of their exchanges with students without engaging in any linguistically sophisticated analysis. However valuable as a stimulus to reflective practice, such studies raise difficult questions about how immediately and directly open to interpretation those exchanges are. If spoken language is not treated as a transparent medium, something to be looked through rather than looked at, then how far is it possible to apply methods of 'looking' without extensive knowledge of the specialized academic areas from which they derive? From a linguistic perspective, it is argued that researchers can only scratch the surface of classroom language if they merely select as evidence whatever features appear to be pedagogically interesting; 'principled' analysis of linguistic forms is a necessary condition for revealing their functions. It may also be argued that, with notable exceptions (e.g., Bernstein 1996, Cazden 1988), sociolinguists have tended to neglect classroom talk as a setting for fundamental research.

Different ways of investigating classroom talk will now be outlined to emphasize how the researcher's purposes shape the methods which are used and reflect certain assumptions about the phenomena being observed (see also Edwards and Westgate 1994).

1.1 Systematic Classroom Observation

Practitioners of this approach certainly 'look through' the language being exchanged. The decision is made to code what is said by teacher and students using a schedule which preselects those features of their interaction which are judged to be relevant to the inquiry. This practice of 'systematically' coding classroom events as they happen, depends on a certain positivist confidence in their 'transparency.' Most obviously, it assumes that the words being exchanged can be treated as conventional tokens of a shared situational understanding and their functions appropriately categorized (see Galton et al. 1999). This makes it possible to gather evidence from a large number of classrooms in a fairly short time: an hour's observation yields an hour's data immediately available for analysis.

1.2 Ethnographic Approaches

Those who make audio or audiovisual recordings of classroom talk perceive teacher and students as developing and revising their meanings as the talk proceeds, drawing as they do so on background knowledge of which the observer may be unaware. Transcription of the talk makes it possible to examine these subtleties retrospectively. There are large differences in how this is done, notably in how the 'context' of the talk is understood and used in the analysis, how comprehensively the talk is recorded and transcribed, and how much information (for example, about pausing or intonation) is contained in the transcript.

1.3 Insightful Observation

The approach described as 'insightful' observation' might also be termed unsystematic ethnography. For while it usually requires that the researcher spends enough time in that classroom to gain an understanding of its culture, it rarely involves detailed structural analysis of the discourse. The focus is usually on what 'the patterning of communication' (Barnes and Todd 1995: 1) reveals about the simultaneous managing of relationships and meanings in conditions where it is usual for the boundaries between the teacher's knowledge and the students' ignorance to be regularly and sharply marked. This approach has been widely used to identify styles of teaching and learning or, more specifically, to describe the verbal 'scaffolding' through which the teacher enables students to extend their understanding (Edwards and Mercer 1987). Apparently limited demands on the researcher's linguistic expertise partly explain why this approach has been widely used by teachers investigating the opportunities provided in their own classrooms for students to develop skills in talking and listening. It is a form of action research encouraged by recognition of the

centrality of those skills in the learning process (see *Oracy*; *Spoken Language in the Classroom*).

1.4 Linguistic Ethnography

Teachers' control over classroom knowledge is especially evident in the frequency of their questions, and in the frequency with which the consequent exchanges make it evident that the answers are already known to the questioner. Although both the counting of questions and the assessment of their cognitive difficulty (or level) have been commonplace in classroom research, Dillon (1994) has drawn attention to alternative and possibly more effective ways of eliciting student contributions and promoting discussion.

There are also methodological objections to taking questions out of context. In what has variously been called 'linguistic' or 'constitutive' ethnography, the whole structure of classroom discourse is systematically described. Although questioning is still treated as giving rise to 'the essential teaching exchange' of teacher-initiation, student-response, and teacher-evaluation, such regularly occurring sequences are embedded in a comprehensive analysis covering every item of turn-taking and all those methods by which teacher and students secure cohesive and coherent discourse (see Mehan 1979, Cazden 1988). By seeking to derive from the participants' ordering of that discourse the rules from which their situationally appropriate participation is generated, such analysis has drawn attention to possibilities of serious misunderstanding, even of more or less overt cultural conflict, where the rules governing normal communication in home and school settings are at variance (see Heath 1983; and see *Educational Failure*; *Home Language and School Language*; *Black English in Education*; *Standard English and Educational Policy*).

1.5 The Linguistic Structure of Classroom Discourse

From a predominantly linguistic perspective, classrooms have had the empirical attraction that clearly structured relationships are likely to produce linguistically distinctive forms of discourse (see Coulthard 1992). Much of the resulting research has drawn heavily on speech act theory—the investigation of what is done with words, and how it is done, in circumstances where words and meanings are tied together in ways which are familiar to the participants and characteristic of that setting. A common classroom example is the likelihood that *Will you please turn to page 14*, if said by the teacher, will be heard as a directive and not as a polite request admitting the possibility of refusal. Such 'mitigating devices' are used by teachers to soften the edges of their control and make it more indirect. But that control remains pervasively evident in those particular ways of eliciting, displaying, and confirming (or

disconfirming) knowledge which are characteristic of classrooms.

2. Phases of Research Activity

All research traditions carry within them a range of theoretical assumptions about language as social behavior. Before examining the variety of practices which give these assumptions life, it should be made clear that most researchers reject any notion of a single 'right' approach or set of approved procedures. While all research requires hard choices to be made about how data are to be defined and collected, the guiding principle remains one of matching techniques to aims and purposes. This is itself a difficult task, given the range of alternatives and the problem of compatibility which may arise from mixing them.

The search for appropriate techniques can usefully be considered under four phases of activity which are common to all approaches where the language used comes under close scrutiny. Initially, the choices focus upon methods of observing and recording what is said. Varying widely in technological sophistication, these usually result in recordings stored on tape. A second phase makes these accessible to detailed analysis by transcribing them according to conventions and criteria determined by the researcher's particular purposes. The act of transcription is inseparable from that next phase because what is included in the transcript, and how this material is organized, constitutes the data to be analyzed and interpreted. But in contrast to the instant coding of verbal interaction, it is possible to return to the recording and to constitute the data differently—for example, by including features of intonation or pausing which seem retrospectively to be significant. Finally, an analysis grounded in the data has to be made public and warranted, decisions having been made about the amount and type of evidence to be displayed.

These phases are now considered in greater detail.

3. Recording Classroom Talk

3.1 Naturalistic Recording and Its Problems

Classrooms are busy, noisy places with a great deal of movement and simultaneous talk. Some researchers have sought to reduce the technical problems of recording by interviewing individual students as they work, or by removing small groups to a quieter setting (see, for example, Barnes and Todd 1995). Readily audible recordings may then reveal important dimensions of individual performance without having much predictive power about normal classroom interaction. Technical developments have eased this problem. A radiomicrophone may be too costly to give to more than one participant, usually the teacher, while a single static microphone misses too much of the action. More affordable pocket-size

individual recorders now allow the researcher to focus upon several individuals at once and on the evolving contexts of their talk.

It is likely that researchers with predominantly sociolinguistic or pedagogic interests will want to record normally occurring talk. And at least in comparison with such daunting alternatives as the playground, classrooms have seemed a manageable setting because so much of the talk is under the strategic direction of its most powerful participant. Where talk occurs without the teacher being present (e.g., in a small-group setting), it can still be stopped or redirected by the teacher, and its course is usually set or constrained by the teacher's agenda for the class. Moreover, where the teaching is of a more traditionally transmissional style, or where any teacher is conducting whole-class, even whole-class interactive, teaching, even temporarily so, the resulting talk presents a somewhat simplified aspect for analysis as well as for recording. Indeed, it is possible that the greater ease with which recordings can be made in such circumstances may partly explain the common researchers' view that classroom talk is excessively teacher-dominated. While the persistent pedagogical difficulties of affording students more communicative space, or of encouraging their exploratory talk, continue to exercise the minds of researchers and teachers alike, it may be that forms of classroom talk which are not teacher led are simply underrepresented in the literature because of the relative difficulty of recording them.

3.2 The 'Observer's Paradox'

A major problem of validity has been acknowledged by sociolinguists since the outset of their endeavors, namely the effects of observation on the activity being observed. Since eavesdropping is unethical, the problem can never be more than partially solved. Researchers must therefore do their ingenious best to limit the interference caused by their presence, whether by becoming accepted as a familiar nonparticipating observer or by adopting some appropriate auxiliary role where this does not distort the 'natural' situation unduly (see *Observer's Paradox*).

The size and obtrusiveness of the recording equipment may pose obvious problems. Although video recording no longer necessarily requires special lighting, the movements of the filmer can still be conspicuous. By comparison, what compact audio recorders lack in capacity to catch nonverbal or contextual detail, they can more than make up for in simplicity of operation, flexibility of use, and accuracy of sound track. Field notes can add important complementary data if the observer's presence is not resented. In any event, teachers and pupils can usually vouch for the normality or otherwise of events, for their awareness of disruption, and for their feelings about being recorded. Such further data are helpful in estimating how intrusive the researcher has been.

A comparable problem concerns the typicality of any particular setting in which recordings are made. It is axiomatic that any stretch of talk can only be understood in relation to its context. By the same token, questions arise about the extent to which stretches of talk may be so context specific as to be of limited general relevance. Revealing typical structures of classroom communication across various settings is a common research ambition. Alternatively, detailed studies of particular classrooms may be valued for the questions and hypotheses which they generate about other settings and for demonstrating methods of investigation which can be used elsewhere.

4. Transcribing and Analyzing Classroom Talk

4.1 Taking Account of Context

Practices and problems in making classroom recordings have their parallels at the transcription phase. In particular, researchers' working conceptions of 'context' influence their decisions about what to transcribe and how to select different kinds of data for analysis. The customary distinction between 'setting' and 'context' makes the point clear. The former term applies to location and to other 'givens' at the onset of the talk; the latter expresses the complex and dynamic interplay of forces which speakers and hearers attend to (for example, their perception of each other and of the way their utterances, gestures, hesitations, etc., are received) as the talk proceeds. In this sense, a context is talked into existence and evolves. Thus researchers' assumptions and beliefs about what is potentially 'alive' in the contexts they study can be seen to inform their collection and use of data, and partly to determine how far they wish to go in including markers of paralinguistic, nonverbal, or prosodic features rather than relying on a simple transcription of the words.

The rich redundancy of contextual meanings available to the participants also raises difficult questions about how accessible these meanings are to a researcher lacking much of their background knowledge, and about the 'commonsense' understandings of what classrooms are like on which that researcher at least implicitly relies in making sense of what is said. These questions may extend to the researcher's subsequent reliance on the reader's knowledge of classrooms to let the words exchanged by teacher and students 'speak for themselves.' They may entail some reference to 'respondent validation,' the confirmation of an account by the participants themselves (see Mehan 1979). Or, working in a different methodological tradition, the researcher may seek relatively unambiguous 'hard' indicators of meaning in, for example, the speakers' hesitations

and pauses, intonation, or apparent vulnerability to interruption (see *Observer's Paradox*).

4.2 Varieties of Transcription and Analysis

Different approaches to context will now be illustrated through transcript extracts which supply varying amounts of information around the words, and so lend themselves to different forms of analysis. The order in which they are presented reflects a continuum already described: from research which assumes that a verbal record can offer a relatively unproblematical 'window' on to events, through to studies which are more oriented towards exploration of linguistic patterning.

Underlying example (2) is the view that specific accounts of classroom talk are essentially illustrative. Their credibility, like that of commentaries made upon them, derives from professional experience shared between researcher and reader. It is assumed that a plain verbal record will be 'recognized' for what it is by those who possess the relevant situational competence. Little technical sophistication is required of such transcription; here not even pausing is indicated. Interest in the passage is mainly pedagogic, to do with the conflicting views of a pupil and her teacher. The commentator (Mercer 1995) provides some preliminary information concerning the setting: a 15-year-old pupil talking with her class tutor about recent work experience in an elderly persons' social club attached to the school. Assuming that the transcript speaks for itself, he concludes (p. 51) that 'Donna is clearly rejecting her teacher's attempt to "educationalize" her work experience, to treat it as a resource for conventional educational achievement.'

Teacher	Well, you've been working now, you've (1) been going to the frail elderly, helping them for nearly half a term now haven't you?
Donna	Yeh.
Teacher	So I was wondering about whether you might think now might perhaps be a good time to start to write something down about it.
Donna	Don't know, it would make it seem more like work than fun, wouldn't it? Make it more like a normal schoolday, because I enjoy it so much.
Teacher	But for your final folder, for social sciences, it would make a really good project wouldn't it? It would look pretty good in the folder if you could put something together like that.
Donna	I think it would change my attitude while I was there. It'd feel like I was interviewing them or something.

The transcription conventions here are broadly literary in character; like those of a play-script but with more open punctuation. This makes the transcript easy to read, but may lose information which the participants themselves used in interpreting what was said. It therefore carries the risk of making the talk seem simpler than it was. It is therefore more usual practice to combine such everyday features as capital letters and full stops (periods) with a range of symbols specific to the technical requirements of sociolinguistic research.

There are variations within this range, but some of those commonly used are found in (2) as follows:

(...)	Words undeciphered (2)
:	Discourse omitted as irrelevant to the issue discussed
/	Pause of less than 2 seconds
//	Pause of more than 2 seconds
bold	Emphatic speech
[	Simultaneous or interrupted speech
(&)	Continuing speech, separated in the transcript by an interrupting speaker

These are the conventions used by Edwards and Mercer (1987: ix–x), who describe their research purposes as being:

> ...not to produce an analysis of linguistic structure, but to provide the sort of information that is useful in analyzing how people reach common understanding with each other of what they are talking about.
>
> (Edwards and Mercer 1987: ix)

Pauses, interruptions, and the emphasizing of particular words are all well-suited to such a purpose. Indeed they can constitute valuable data for understanding various aspects of classroom talk. Whole-class teaching, for instance, tends to be fast-paced partly because teachers see pauses as entailing risks to their control of turn-taking. In a setting where teachers normally own exclusive rights over the allocation of turns at talk, interruptions are similarly exceptional. Indeed, just-perceptible pausing on the part of the teacher, in conjunction with other subtle changes of cadence and postural shifts, can function to signal a topic-boundary or a moment at which interruption becomes permissible (see Cazden (1998: 9–10) for a similar attention to pauses). Word-emphasis may also take on significance for conveying value attached to a technical term, or for identifying metastatements designed to encapsulate established knowledge. Such data can be seen to interact powerfully with pragmatic information, as in the extract (3) which comes from the first of a sequence of lessons on pendulums video-recorded in a class of 10- and 11-year-olds (see Edwards and Mercer 1987: 137–38). During this talk, the pauses appear to mark the speakers' reflection on what is being said, while the simultaneous utterances reflect their urgency. Moreover, a rhyming couplet—'The shorter the string, the faster the swing'—is given weight by the teacher is an important summarizing formula. This extract has to be lengthy because it also demonstrates the tying of meanings over extended sequences of talk.

Participants in talk may also rely heavily upon intonation to remove ambiguities in what they hear. Towards the more linguistic end of the theoretical continuum are found researchers who, in recognition of this fact, attempt to set down on paper all those perceptual cues that participants rely on in their on-line processing (Gumperz and Berenz 1993: 92). Notable among them are Wells and his associates, whose detailed description of language development from infancy through the early years of schooling included a range of prosodic features (see Wells 1985; also *Conversation Analysis; Discourse*).

The database for this project came from recordings using radio-microphones, talk being sampled by means of a time-switching device which functioned without speakers being aware of it. Insight into the processes whereby growth in structural and semantic control is 'negotiated' through interactive talk depended upon close scrutiny of the children's discourse and of the meanings exchanged. Transcripts were thus heavily analytical and noted a wealth of prosodic detail as well as text and pragmatics. The absence of such features in transcriptions of classroom interaction reflects difficulties posed by the greater complexity of such contexts. This is why it is a parent–child exchange (4) which is now used to illustrate the most technically detailed form of notation (Wells 1985: 38). J is playing with the laundry as her mother washes up. The transcript displays the talk in separate columns: J's on the left,

her mother's in the middle, with pragmatic notes on the right.

Although space prohibits reproduction of these transcription conventions in full, they are set out here in enough detail to raise questions about what would be gained in classroom transcriptions if similar information were included. The double-slash symbol (//) here marks the beginning or end of a 'tone-unit,' which itself may coincide with all or part of an utterance. Each tone-unit is numbered for ease of reference here, though numbering of utterances is a more common practice. A preliminary stress mark is used to denote both a prominent and a tonic syllable. Both types of syllable may also be shown in CAPS, being then preceded by two digits (1 to 5) each of which denotes a 'band' of pitch. The figure 1 marks a high, and 5 a low, pitch in relation to that speaker's normal range. Together, the two digits thus indicate the height, the direction, and the extent of pitch change for that element of the tone-unit. Upward or downward arrows show a pitch to be high or low against what is normal for the speaker; a double arrow shows extra high or low variance. Increasing speed is marked by ('accel.'), while a digit between two pairs of dots gives the length of a pause in seconds. Lastly, the symbol (v) indicates that 'the preceding word was used as a vocative, to call or hold the attention of the addressee' (Wells 1985: 177 gives the complete coding system). These details make it possible to recapture, for example, the intensifying

T:	(…) point seven three. So the shorter the string/what? What happens when you shorten the string?	T looking with Antony at his matrix of recorded timings. (3)

```

quality of J's mother's prohibitions which are revealed by the stress and fall–rise intonation in 6 and by the increasing speed and rising pitch of 7, with the downward sweep of its final 'no'. They also, of course, make the transcript very difficult to read.

A simpler system is briefly employed by Cazden (1998: 9), when she makes use of intonational data to identify a particular student strategy for avoiding potential interruption of an oral narrative by either teacher or peers. The strategy involves a 'sharing intonation' which is marked in the transcript by a rising arrow as, for example, (5):

Well when I slept' over my mother's/
  the cat/
  in the middle of the night she w – /   (5)
  she went under the covers/

Some forms of analytical transcription pay more attention to the structuring of lessons treated as speech events than to prosodic detail. The pioneering work of Sinclair and Coulthard (see Coulthard 1992) drew on speech act theory to investigate how things are done with words in classrooms. By revealing organizational principles operating at the supra-sentential level, and so throwing light on how cohesion is achieved in spoken texts, their analysis proved effective in highlighting the special character-istics of teacher-led discourse. Their methodology proceeds by assigning stretches of talk, from utter-ance upwards, to various categories defined by function, from Act 'upwards' through Moves, Exchanges, and Transactions to the complete lesson (for a fuller commentary, see Edwards and Westgate 1994: chap. 6).

This form of analysis has proved seminal in demonstrating the extent of teachers' dominance over the marking of various boundaries within the lesson, their management of turn-taking, and their control over content. Thus Mehan's comprehensive 'grammar' of lessons included a detailed account of how students' developing competence in finding 'the seams in the essentially teacher-controlled discourse' enabled them to take occasional ini-tiatives themselves (Mehan 1979: 139; see also Cazden 1988: 31–51). This is part of a wider competence required of students if they are to participate appropriately in classroom dis-course and to adjust to the largely reactive roles assigned to them by transmissional teaching. Discourse analysis also permits some numerical measurement; Wells, for instance, has been able to quantify initiating and responding moves within his data on home and school settings. Such data have thus provided powerful leverage in opening up alternative pedagogic strategies, especially in promoting peer-to-peer exploratory talk which was the focus of much research in the early 1990s (Wells 1999).

Similar coding of talk arising in other than whole-class contexts may enable researches and teachers to evaluate the pedagogic effectiveness of small-group settings. An important dimension of that task concerns associated cognitive activity, which remains at best indirectly accessible to research. Interest however has already been shown in the additional coding of cognition, an influential example being that of Barnes and Todd (1995). They focused upon the interplay between a verbal transcript and a simulta-neous commentary with 'interactional' and 'content' frames. At the level of performance, the talk was coded according to a set of 'discourse moves' (such as initiating, quantifying, contradicting, accepting) and a parallel set of 'logical processes' (to do with proposing a cause, categorizing, putting an alter-native view, etc.); at a second, competence-related level, the two frames corresponded on the one hand to 'social skills' (such a supportive behavior), and on the other to 'cognitive strategies' (setting up hypoth-esis, using evidence, etc.) and 'reflexivity' (monitoring one's own speech and thought, showing awareness of strategies, etc.). Importantly, Barnes and Todd found the relationship between spoken language and processes of thought to be highly problematical: it certainly could not be handled on any one-to-one form–function basis. Their work had thus to retain that interpretational quality which can never be quite

eradicated from even the most 'principled' and systematic of inquiries in this field. In this context, it will be interesting to follow the developing use of computers, not only as a stimulus to cooperative talk in class-rooms, but as a complementary tool for analyzing that talk (see Wegerif and Scrimshaw 1997).

4.3 Reporting Classroom Talk

At the reporting phase, similar considerations affect the amount and type of evidence to be displayed. Whether interpretation of recorded talk is considered to be self-evident to those who share the culture of the classroom, or whether the support of various transcriptional and analytical procedures is called upon, reporting has initially to be selective. Illustrative passages have to be chosen, and ways found of relating such extracts to the full range of data, so that readers can assess the validity of a given interpretation. However, even if (as Mehan insists) the entire data corpus is made potentially available for rescrutiny, problems persists concerning the extent and form of data to be provided. As at every other stage of classroom language research, there are no absolute solutions to these problems. The form of reporting adopted is similarly constrained by the form in which data were constituted, itself a response to the purposes of the research and the audience for which it is intended.

Reliability/Validity

E. Babbie

In social research, reliability and validity are two criteria for judging the quality of measurements. 'Validity' refers to whether the measurement technique captures the intended meaning of the variable. 'Reliability' refers to the dependability of the technique.

1. Measurement and Concepts

Measurement is a central issue in social research. Both description and explanation depend on the researcher's ability to devise and execute procedures for observing and classifying those observations in terms of variables. More specifically, this task involves the classifying of those being observed in terms of the 'attributes' comprising the 'variables' under study.

In a simple example, the gender of respondents might be measured in a survey: that is, each respondent would be identified with one of the attributes—male or female—comprising the variable, gender. The procedure for accomplishing this would be straightforward, perhaps by asking respondents to check one of two boxes: [ ] Male, [ ] Female. Because this item taps what is generally meant by the term 'gender,' it is probably a valid measure, and as such would be expected to be reliable as well.

To distinguish between validity and reliability further, consider this illustration. Imagine stepping on a bathroom scale that registered a weight of 130

809

pounds. Now imagine stepping repeatedly on the same scale, with the following results: 115, 140, 120, 190, etc. That scale would be judged an unreliable measuring device. By contrast, if it faithfully reported 130 every time the same person stepped on it, it would be judged reliable. Notice, however, that the scale's reliability does not guarantee its validity. If the person really weighed 110 or 210 pounds, the scale would be judged reliable but invalid.

The issues of reliability and validity apply to all social research measures. Unfortunately, most variables of interest are not as tidy as weight and gender, and thus the nature of social research variables must be examined. Most of the variables of interest to linguistics are themselves linguistic, for example, the various ways a word may be pronounced by different speakers, but many other variables may be associated with variations in language and thus be important for sociolinguistic studies.

All variables begin as 'concepts': ideas that represent experiences and thinking. Some common social science concepts would include social class, bureaucracy, alienation, kinship. Variables are concepts comprised of sets of mutually exhaustive attributes or characteristics. Thus, reviewing the list of concepts just presented, social class is a variable: comprised of attributes such as lower class, middle class, and upper class.

Bureaucracy is *not* a variable, however. It could, though, be seen as one of the attributes comprising Max Weber's variable, 'forms of social organization' (the other attributes being 'charismatic' and 'traditional').

Alienation is a variable, comprised of attributes such as low, medium, and high. Finally, kinship is not a variable per se, though 'type of kinship system' could be a variable used to describe societies; the attributes might include: patrilineal, matrilineal, egalitarian, for example.

From this perspective, measurement is a matter of identifying units of analysis with the attributes comprising the variables under study. In a linguistic survey of Canada, it might be required to measure the variable, 'language used at home,' with the attributes of that variable being 'English,' 'French,' and other languages.

The examples given above should illustrate that variables are constructed by the researcher rather than existing in nature. Consider the example of 'social class.' Though it might be comprised of the attributes, lower class, middle class, and upper class, this structure might be inappropriate to some research purposes. W. Lloyd Warner, in his examination of 'Jonesville,' distinguished lower-lower, upper-lower, lower-middle, upper-middle, lower-upper, and upper-upper classes. A Marxist analysis, on the other hand, might require attributes such as proletariat, bourgeoisie, etc.

The process of specifying the nature of variables prior to measurement is called 'conceptualization.' Choices are made among options and ambiguities are clarified.

'Operationalization,' the next step in this process, specifies the concrete procedures (operations) that will result in measurements of the variable in question. The statement of precisely how a variable will be measured and what observations will correspond to specific attributes on that variable is called the 'operational definition' of the variable.

Thus, in a survey of college students, the variable, grade point average, might be measured by asking respondents to answer the question: 'Approximately what was your grade point average as of the end of last term?' Or, alternatively, the researchers might be able to extract grade point averages from the registrar's files and add that information to the data collected by the questionnaire. The operational definition, in the latter instance, would be 'the grade point average recorded in the Registrar's student files.'

It is the operational definition of a variable—specifying what observations will be made and how those observations will be converted into attributes of the variable in question—that can be evaluated in terms of its validity and reliability. There are several aspects of each.

2. Validity

The validity of a measurement refers to the extent to which it measures what the researcher intends, or whether it actually measures something else. Asking students to report their own grade point averages, for example, might be criticized as possibly measuring what the respondents would like the researcher to think about them more than their actual scholastic achievement.

There is a basic, philosophical issue to be acknowledged before proceeding with this evaluation, however. Virtually all the variables studied by social scientists reflect concepts which were products of the mind. Their meanings are ultimately only what people agree they are. 'Social class,' for example, does not exist in nature, but only as a concept created for the purpose of organizing a set of observations regarding differential wealth, power, prestige, etc. Therefore the question of whether a particular operational definition of a variable really measures that variable rests on agreement as to the meaning of the variable in the first place, and people often differ in their use of such terms. This caveat notwithstanding, there are useful grounds upon which to judge the validity of measurements.

2.1 Face Validity

Despite some disagreements as to the meanings of concepts, there has to be some level of agreement or

else people could not communicate through the use of the terms that refer to those concepts. 'Face validity' refers to the extent of agreement between a measurement and the common consensus as to what the concept in question means. Thus, despite disagreements regarding the meaning of social class, few would deny the relevance of measuring annual income in that context.

It is worth noting that annual income is an imperfect measure of social class, even of wealth. Someone with a trillion dollars in their home safe yet earning no annual income is undeniably wealthy. Or conversely, imagine someone with a substantial income but even more substantial debts: such a person might be bankrupt on balance. Still, annual income has face validity as a measure of social class, whereas a measure of, say, height would not: being able to see over other people's heads is not what is commonly meant by 'upper class.'

2.2 Criterion-related Validity

Another standard of validity involves its predictive power. Often, variables are measured in order to estimate some future behavior. Thus, a test of 'marital compatibility' might be devised in the hope of predicting whether prospective marriages would be successful or not. A study examining the extent to which the test actually correlated with the subsequent success or failure of marriages would provide a standard by which to evaluate the adequacy of the test.

Other examples where 'criterion-related validity' might easily apply could include college entrance exams as predictors of college performance, drivers' tests as predictors of driver safety, measures of political attitudes as predictors of voting behavior, etc.

2.3 Content Validity

Given that social science variables typically reference a diversity of meanings, the measurement of a variable can also be judged on the extent to which it successfully captures the different aspects of that variable.

Thus, for example, Charles Glock (1965) delineated five major dimensions of 'religiosity': belief, ritual, cognitive (knowledge), experiential, and consequential (the impact of religion in a person's life). It would be reasonable to ask, therefore, which dimensions were tapped by a particular measurement of religiosity. If a measure of religiosity that used only church attendance and praying before meals was constructed, that measurement technique could be reasonably criticized as omitting several meanings commonly associated with the term. Of course, it might be appropriate to limit the measurement, in terms of the aims of the particular study; in such a situation, it might be wiser to relabel the measurement as 'religious ritual.'

By the same token, it might be asked whether a particular measure of 'prejudice' focuses on prejudice against one or a few groups or somehow captures the idea of prejudice in general. Measures of liberalism and conservatism may tap only domestic or foreign-policy dimensions or both; similarly, liberalism and conservatism can refer strictly to politics or to morality, lifestyle, and other social issues. As a criterion of quality, content validity asks that the label assigned to a measurement cover whatever breadth of meaning is commonly associated with that term.

2.4 Construct Validity

'Construct validity' refers to how well the measurement of a particular variable articulates the place of that variable within a network of causal relationships with other variables. Whereas criterion-related validity tests the extent to which a measurement relates to other measures of the variable in question, construct validity is a matter of the measurement relating to measurements of other variables as expected on logical, theoretical grounds.

Thus, for example, a measure of alienation might be developed, based on answers to a number of questionnaire items. On theoretical grounds, there may be a number of expectations about alienated people: they might be less likely to vote, less likely to marry, and more likely to contemplate suicide than would be the case for less alienated people.

It would be reasonable to expect therefore that the measure of alienation would be negatively correlated with voting and marrying and positively correlated with reports of contemplated suicide. The failure of any one of these correlations should give cause for questioning the validity of the theoretical expectations; the failure of all should also call into question the construct validity of the measure itself.

3. Reliability

Whereas validity is a matter of measuring what it is said is being measured, reliability merely asks whether the measuring has been carried out dependably. The basic metaphor for reliability is repeated measurements of the same thing—with the same result produced each time, for example, earlier in this article the example of the same bathroom scale repeatedly, getting the same weight each time was discussed.

Unfortunately, many social science measurements do not lend themselves to such straightforward reliability testing. In a survey, for example, the same question cannot be asked repeatedly. And even if it could be, the respondent would remember his or her earlier answer and simply give it again.

Despite these difficulties, there are techniques that provide tests of reliability in social research.

3.1 Test–Retest Method

Having said that the same question cannot be asked repeatedly of the same respondent, it is nonetheless sometimes possible to repeat questions to a more limited extent. In a lengthy questionnaire, for example, it might be possible to ask the same question in different locations without drawing the respondent's attention to what is being done.

In studies that involve data collection at more than one point in time, the same question can be asked at different times, allowing an evaluation of the consistency of responses. This practice sometimes produces surprising results, however.

When Sacks and Krushat (1980) asked many of the same health and demographic questions in two surveys, three months apart, they found that only 15 percent of the respondents gave exactly the same answers. Whereas all subjects were presumably three months older, one seemed to have become five years younger. One respondent's mother aged 20 years in three months. One woman reported a missing ovary in the first survey but had evidently found it by the time of the second survey.

3.2 Split–Half Method

The test–retest method can be approximated through a somewhat different technique, if the researcher has several indicators of the variable in question. If the several indicators offer *valid* measures of the variable, then they should be correlated highly with each other. Whether they do so in fact can be taken as a test of reliability.

To give a simple example, suppose it is required to measure how 'fat' respondents are: how wide they are in relation to their height. As measures of their width, they could be asked to report the size of their waists, chests, thighs, forearms, necks, and hips. It seems obvious that any of these measures, in relation to height, offers a valid measure of how fat respondents are. In practice, however, the reports might not correlate as well as would be expected, due to the fact that people may be aware of their waistline measurements but not know the other measurements. Many of their reports, then would be estimates of less than perfect reliability.

In testing the reliability of social science indicators, the several indicators might be randomly assigned to two subsets: each providing a valid measure of the variable. All the indicators would be included in a single questionnaire. Each set of indicators would then be used to classify respondents in terms of the variable, and the two classifications would be correlated.

3.3 Standardized Measures

Since science is a cumulative enterprise, with current research growing out of and beyond the past, it is sometimes possible to choose measures that have been developed, tested, and generally accepted as reliable measures of particular variables. The US Census Bureau, for example, has established numerous definitions and measurement techniques addressing a number of demographic concepts. In addition to profiting from previous reliability testing, it is possible to compare findings with those of other studies using the same measures.

Many measures are standardized informally, by the weight of repetition among researchers addressing a particular concept. The Srole Anomia Scale is an example of this.

3.4 Coder Reliability

The question of reliability is not limited to asking questions and getting answers from respondents. Sometimes the measurement process includes the coding of textual materials, such as answers given to open-ended questions (e.g., 'What do you consider the biggest problems facing the nation today?'). To support quantitative data analysis, such answers must be converted to standardized code categories (e.g., 'crime,' 'pollution,' 'recession,' etc.). This process has two stages: (a) establishing the set of appropriate codes and (b) actually assigning textual responses (e.g., 'It's not safe to walk the streets anymore') to the appropriate code category (e.g., 'crime').

The coding of textual materials involves subjective judgments on the part of the coder(s). When more than one person does the coding, there is a danger that they will have somewhat different interpretations of the code categories and will not make comparable assignments. The easiest method for checking against this possibility is to select some subset of the materials (40 or 50 questions, for example) and have all the coders process the selected materials. You can then determine the 'intercoder reliability.'

Even if all the coding was done by one person, it would be good practice to recode some of the materials, after a suitable passage of time, to see if the interpretation is consistent.

4. Tension Between Reliability and Validity

The best measurements are those ranking high in both validity and reliability. It is worth noting in conclusion, however, that a certain tension exists between the two qualities. Increasing one often reduces the other.

Imagine a study with the aim of classifying people in terms of their religiousness. A fairly reliable measure would be represented by asking the question, 'How many times, if any, did you attend worship services during the past week?' The number of times reported would then constitute a scale of religiousness. Names might even be given to levels on the scale: 'extremely religious' for attending worship

812

services seven or more times during the week, 'very religious' for 2 to 6 times, 'religious' for attending once, etc.

The above measure is probably a *reliable* one in that people should be able to recall accurately how many times they attended worship services during the past week. Its *validity* is subject to question, however, since attendance at worship services is only a small part of what would normally be meant by the term 'religiousness.' Moreover, one can think of reasons why a 'truly religious' person might not have attended worship services (e.g., hospitalized that week) or why nonreligious people might have attended (e.g., brought unwillingly by an insistent spouse or parents).

A more valid approach might involve unstructured, hour-long conversations with respondents, probing their beliefs about supernatural matters, their support of religious institutions, a wide range of religious practices, feelings, and behaviors regarding moral/ethical matters, etc. By the end of each interview, the researcher might be confident about gauging how religious that person really was. In any event, the interviewer would feel more confident of the judgment than if the only information available was the answers people gave to the simple question about worship services.

While the latter approach can offer more validity, it comes at a price in terms of reliability. Different interviewers, for example, might judge the same respondent differently. A respondent's inability to express complex ideas and feelings might lead to an inaccurate assessment. Many other factors conspire to make this more valid measurement technique potentially a less reliable one.

The solution to this dilemma is to use a variety of measurement techniques—varying in validity and reliability—whenever possible. These several indicators of a variable can be compared and perhaps combined in the analysis.

Salvage Work (Endangered Languages)
N. C. Dorian

1. Introduction

Linguistic salvage work deals, by definition, with endangered languages. The term itself indicates that the state of the language in question allows only limited opportunity to achieve a degree of documentation, that is, to 'salvage' some record of the structure of a distinctive language or dialect. General descriptive documentation goals are neatly summed up under the GDT acronym: a *g*rammar, a *d*ictionary, and a collection of *t*exts are considered (assuming a conscientious and competent researcher) to represent a language reasonably adequately in terms of the scholarly record. Sociolinguistic or anthropological linguistic documentation goals usually include, at a minimum, some account of the circumstances (in historical, political, social, and economic terms) which have made the speech variety in question precarious enough to call for salvage work.

2. Salvage Work in Descriptive Linguistics

Within descriptive linguistics a sense of the urgent need for salvage work emerged strongly, if belatedly, in areas of European settlement where indigenous peoples had been brought close to extinction by settlers' profoundly negative impact on indigenous health and subsistence modes. Many such areas were inhabited by a variety of distinctive peoples with small populations highly vulnerable to settlement pressures. Earliest settlement areas within a region suffered the worst losses (e.g., coastal eastern North America, coastal southeastern Australia). Recognition of the losses gave impetus to extensive fieldwork efforts on the part of linguistic fieldworkers. Locating last speakers of Native American languages and recording what he could of their languages occupied the American field linguist John Peabody Harrington (1884–1961) for an entire professional lifetime, for example. Few linguists have documented as many endangered languages as Harrington did, but some contemporary scholars have devoted years to documenting a variety of threatened languages in a region or a country, as have Bernd Heine in eastern Africa and R. M. W. Dixon in Australia.

3. The Evaluation Problem in Salvage Work

After locating speakers willing to serve as sources for an endangered language and beginning work, fieldworkers often face problems in evaluating the material obtained. If several speakers are available, their versions of traditional stories or their individual responses to questions can be compared, with some likelihood of identifying one or two speakers whose usage is particularly intact or conservative. If only one speaker is available, or only one proves healthy or receptive enough to take on the role of language consultant, the researcher necessarily falls back on more indirect indications of proficiency. Material gathered previously by another linguist working on the same language may provide a comparison with a current speaker's materials, though the value of this approach depends on the reliability of the predecessor's records and the proficiency and forthcomingness, in turn, of the source(s) on which he relied. In some cases there may be closely related speech forms with which the materials from the language under study can be compared. Apparent fluency is not necessarily a good indicator of an individual's usefulness as a native-speaker source. Long disuse of the language or reticence with strangers may make a proficient source hesitant in manner, while a desire to appear knowledgeable may cause an individual with very incomplete knowledge to adopt a manner of expertise and certainty. In particularly fortunate cases final speakers, who have not used their ancestral language for a long time, may begin work with poor recall but gain confidence and regain a measure of proficiency as work proceeds.

Even when final speakers prove thoroughly fluent, if no community of speakers making fairly regular use of the language remains, there is good reason to be cautious about the material obtained. The seasoned American fieldworker Mary Haas worked for example with an apparently fully fluent last speaker of the Native American language Tunica, but she took the material that she gathered from him to be only a remnant of what Tunica would have been like when it was the everyday means of communication for a community of speakers. The reasonable assumption behind her caution is that peoples' command and deployment of language resources is fundamentally social in nature and consequently maintains its full richness only in an interactive social context.

4. Sociolinguistic and Anthropological Linguistic Salvage Work

The methods and concerns of salvage work differ considerably according to whether the linguist undertaking the work has objectives primarily of a descriptive, typological, or historical sort or has, instead or as well, objectives of a sociolinguistic or anthropological linguistic sort. Descriptivists, typologists, and historical linguists work largely without reference to social context, whereas sociolinguists and anthropological linguists consider such a context an important element in their research.

4.1 Investigating Social Setting: Interplay of Language Ideologies and Language Behaviors

Anthropological linguist Lukas Tsitsipis studied imperfect renditions of the receding language Arvanitika, a form of Albanian enclaved in Greece for some 500 years, produced by terminal speakers in two communities. He found that these imperfect speakers tended to interrupt the Arvanitika narratives of older and more fluent speakers, often inserting oddly incongruent Arvanitika material such as list-like word sets or contextually inappropriate high-frequency formulaic phrases into their elders' narratives. Although it was true that the terminal speakers were not fully fluent in Arvanitika, focus on ideological and pragmatic features of the language setting revealed that it was not so much their lower proficiency as their ideological differences from their elders that led to the incoherent-seeming interruptions. In consciously disrupting fluent Arvanitika narratives, the imperfect younger speakers were reacting to the ideological and functional subordination of Arvanitika to Greek, and also to the political subordination of the Arvanitika speech communities to the surrounding Greek world. The terminal speakers had accepted a pragmatic worldview in which Greek was highly valued and Arvanitika was not, and their interruptions served to distance them both from the conservative worldview of older people who continued to use Arvanitika regularly and from the older speakers' linguistically subordinate position relative to Greek.

Tsitsipis' study of the way in which language ideology affected language use is a good example of the insistence on monitoring the interplay of language behavior and social context that informs sociolinguistic and anthropological linguistic salvage work. The process of shift from Arvanitika to Greek among younger people in the Arvanitika communities was reflected not just in the terminal speakers' lesser control of Arvanitika grammar, but also in the way they actively used what they knew of Arvanitika to disrupt the fluent language performance of their elders. Language ideology and cultural values are often implicated in choices about language transmission and acquisition, and therefore also in language maintenance and shift processes quite generally. In one village setting in Papua New Guinea, where the ancestral language had come to be associated in speakers' minds with childish, womanish, and heathenish ways, careful observational research indicated that parents were unconsciously promoting

their children's acquisition of the nationally current language Tok Pisin and discouraging the acquisition of the local vernacular, Taiap, even though those same parents claimed to be surprised and disappointed that their children were not speaking their own ancestral language (Kulick 1992). Among the children and grandchildren of Gaelic-speaking fisherfolk in East Sutherland, Scotland, moving away from the home community for the sake of job opportunities often had the effect of increasing the symbolic value of the home language that the exiles had regularly heard and irregularly spoken in childhood. The experience of exile, combined in a good many cases with strong affective ties to older-generation kinfolk in the home villages, prompted a number of returned exiles to emerge as adult Gaelic speakers, imperfect in their control of Gaelic structure but loyal to the language beyond the degree usual for their age-group (Dorian 1981) (see *Language Maintenance, Shift, and Death*).

4.2 Investigating the Deployment of Linguistic Contact Phenomena in Endangered Languages

Changes in the phonological and grammatical structure of languages passing out of use are of interest to linguists for the light that they throw on processes of convergence, simplification, reduction, and outright loss during contact between languages. Apart from such matters, sociolinguists are interested in the way linguistic phenomena characteristic of language-contact settings are deployed, e.g., code-switches, borrowings, coexisting discourse markers, or cross-linguistically quoted speech. To take code-switches as an example, switches have been found to have quite various motivations. Low proficiency on the part of a speaker can lead to code-switches, but so too can high proficiency when all parties to an interaction share knowledge of the same pair (or set) of languages. Furthermore, code-switching can be a useful social compromise when a speaker wishes to avoid identifying more strongly with one language than another or wishes to avoid the connotations that use of one or the other language might have among a particular group of people or in a particular setting. Community-wide attitudes towards code-switches can be equally diverse. Unremarkable in some speech communities or social networks, code-switches are strongly disapproved of in others. In endangered-language settings, an individual aware that she represents a rapidly receding language may self-consciously try to avoid code-switches in work with a language researcher. If switching nonetheless proves frequent, evaluation of this behavior may again be difficult, since comparisons across the usage of a community of speakers are needed in order to determine whether code-switches represent a widespread and commonplace practice or

whether they are appearing only late in some speakers' lives as a product of disuse of the receding language.

4.3 Sociolinguistic Salvage Work and the Speaker Community

Descriptive salvage work can sometimes be undertaken with moderate success when there is only a single source to work with, or a few scattered and isolated sources, but this is scarcely possible with sociolinguistic salvage work. The issues mentioned above, together with other context-related issues (e.g., the relative importance of topic, domain, and interlocutor in code selection; the differentiation and interplay of identities associated with the languages in a multilingual's repertory), are directly investigatable only when at least a small community of speakers continues to use the receding language. Last speakers' memories can be consulted but are seldom completely reliable on such socially sensitive matters. Sociolinguistic salvage work therefore needs to be undertaken before language shift is so far advanced as to leave only scattered elderly members of the ethnic population as speakers. Furthermore, because social context and social behaviors are humanly complex, fieldwork of this sort calls for fairly extensive familiarity with the language setting and with speakers' language behaviors. Relatively long periods of residence in the speakers' community, repeated field trips, or both, are often entailed.

Scholars disagree sharply about what the linguist's role can or should be where endangered-language research is concerned. According to one school of thought, linguists are professionally competent to document language structures but should refrain from involvement in any programs the community is undertaking to support its own language, since this lies outside their competence. Another school of thought contends that linguists assume obligations when they do research based entirely on other people's sharing of their knowledge, and that honoring such obligations makes it incumbent on linguists to acquire the skills necessary to honor community requests for language-related assistance, e.g., by producing teaching texts or user-friendly dictionaries.

Scaling

E. Babbie

Throughout the social sciences, it often becomes necessary to measure a variable through a combination of several pieces of information, and a variety of techniques have been developed outside linguistics that can be employed profitably in language studies. First, sociolinguists need scaling techniques in order to measure the social variables they correlate with variations in language. Second, language variations themselves may often be measured most accurately through scales, rather than by relying upon single bits of data or upon intuitive summary judgments. Finally, scaling techniques rest on the linguistically interesting observation that people can seldom if ever express their attitudes validly and reliably in a single utterance, but need several utterances such as the answers to an entire set of survey questions.

1. The Logic of Composite Measures

It could be said that all social research is about the description and interrelating of variables. For example, Basil Bernstein's famous research related the variable of social class to speech codes; and other researchers have compared the speech of women with that of men. In either case, *measurement* is a fundamental element in social research: the classification of individuals (or other units of analysis) in terms of the relevant variables. Sometimes, measurement is relatively simple and straightforward, as in the case of gender, which can be determined readily through a single question. Many of the variables that interest social researchers, such as social class, authoritarianism, alienation, prejudice are not so simply measured. Such variables call for a more sophisticated measurement strategy.

In those cases where no single piece of information will represent the meaning of a complex variable *reliably* and *validly*, the solution is to construct a measure from several independent pieces of information. This is especially appropriate when the purpose is to measure a variable comprised of several attributes, representing different levels of intensity of degree. Thus, prejudice might be represented by the attributes: Extremely Prejudiced, Very Prejudiced, Somewhat Prejudiced, Slightly Prejudiced, Unpreju-

diced. Or, intelligence, is sometimes represented by the scores of an IQ test: 100, 101, 102, 103, etc.

The construction of composite measures is based on two assumptions: (a) that the theoretical variable under study actually represents a dimension of variation among people and (b) that there are numerous indicators of that variation. In the case of prejudice, for example, it is assumed that some people are more prejudiced, in general, than others and that there are several pieces of information attainable about people that offer clues as to how prejudiced they are.

The first assumption should not be accepted as obvious. It is not necessarily the case that those prejudiced against Jews, for example, would also be prejudiced against Blacks, against women, or, particularly, prejudiced against Arabs. Variations in prejudice against Jews, then, may occur more consistently than variations in prejudice in general. Thus, if it can be said with greater certainty that Person X is more prejudiced than person Y then one can say that Person X is more prejudiced than person Y in general.

Once the assumption is made that people do vary on the variable under study, it can be assumed further that there are several indicators of that variation. Agreeing with the statement that 'Jews tend to cheat in business' would be one indicator of antisemitism. Similarly, agreeing with the statement that 'Jews are clannish' would be another. Another possible indicator would be agreement with the statement that 'The Jews are God's Chosen People,' in this case, representing the *opposite* of antisemitism. Both positive and negative indicators of variables can be appropriate to composite measures.

There are several techniques for combining indicators into composite measures.

2. Simple Cumulative Indexes

The simplest method for creating a composite measure of a variable is to identify some list of indicators of that variable and give each subject a score equal to the number of those indicators that apply to them.

To measure levels of political activity among a sample of people possible indicators might include answers to the questions, asked in a survey questionnaire:

'Did you vote in the last election?'
'Have you ever contributed money to a political campaign?'
'Have you ever volunteered to work on a political campaign?'

Primarily, such indicators are selected on a *prima facie* basis, though it is often a good idea to test the empirical relationships among indicators. If voting and contributing money are both indicators of political activism, for example, it would be reasonable to expect that voters would be more likely to give money than would the nonvoters—and vice versa.

Having asked these three questions, subjects could be given one point for each 'yes' answer. The result would be a simple index ranging in scores from 0 (said 'no' to all three questions) to 3 (said 'yes' to all three).

In creating a measure such as this, the resulting index will be assumed to have the quality of *ordinality*: that those with scores of 3 are more politically active than those with scores of 2, who are more politically active than those with scores of 1, who, in turn, are more politically active than those with scores of 0.

Index scores could then be used for purposes of determining the relationship between political activism and other variables. To determine whether men or women were the more politically active, the average index scores for men and women could be calculated: if men had an average score of 2.5 and women had average scores of 1.0, it would be concluded that men were more active than women. (In lieu of such an index, comparison could be made of the percentages of men and women who vote, who have contributed money, and who have volunteered.)

Similarly, a composite index would allow the exploration of the consequences of political activism. Table 1 would suggest that politically active people are less likely to attend church than the politically less active.

Simple indexes like this one have two major weaknesses. First, the several indicators of a given variable often represent different levels of intensity. For example, volunteering to work on a political campaign seems a stronger indicator of political activism than simply voting. Yet in the simple index

Table 1.

	Index of Political Activism			
	0	1	2	3
% who attended church during week ...	60	52	43	35

described above, all three indicators are treated equally. The scaling techniques to be discussed below take account of the differing intensities of indicators.

Second, while simple indexes usually represent *ordinal* measures of variables, some of the scales which will be examined seek to create *interval* measures: with equal increases of intensity separating the categories on the scale. In the political activism index above, for example, it is assumed that those with a score of 3 are more active than those scored 2; it cannot be assumed, however, that the *degree* of activism separating 3s from 2s is the same as that separating 2s from 1s and 1s from 0s. Some of the scaling techniques examined below seek to create equal-interval measures.

3. Bogardus Social Distance Scaling

E. S. Bogardus provides an excellent illustration of the different intensities represented by various indicators of a variable. Suppose that the degree to which people are willing to associate with ex-convicts is to be measured. Presumably some people would generally welcome ex-convicts back into society, perhaps feeling they had paid their debt to society, while others would be less forgiving and/or less trusting. This phenomenon is commonly referred to as the 'social distance' people desire with regard to ex-convicts.

A simple index of the social distance in this instance might be created by asking about relationships people would be willing to have with ex-convicts: buying shoes from them; sitting beside them on the subway, etc. We would simply add the number of such relationships a person would willingly accept.

It is possible, however, to create a list of relationships which, in themselves, represent differing social distances. Consider the following.

Would you be willing to have a convicted child-molester, who had served his time in prison and been released:

... live in your country?
... live in your city?
... live in your neighborhood?
... live on your block?
... live next door to you?
... marry into your immediate family?

Take a minute to answer these questions for yourself. How many did you answer 'yes.' If you answered 'yes' to at least one and fewer than all six, then you should be able to see an interesting pattern in your responses. If you said yes to only one, for example, it probably was the first one: letting the child-molester live in your country; if you said 'yes' to two, they were probably the first two items in the list. If you agreed to five of the six, on the other hand, you probably only objected to the last: marriage into your immediate family.

817

Imagine that these questions were asked among a sample of a thousand respondents. If each of them was assigned a score, representing the *number* of relationships agreed to, those numbers would also—in most if not all cases—reveal the answers given to each of the six questions. For example, the person with a score of 3 probably answered: yes, yes, yes, no, no, no. Such summary *scale scores*, then represent the relative *social distance* our respondents are willing to tolerate with convicted child-molesters. The same technique, of course, could be used to determine social distance with regard to groups based on religion, race, social class, nationality, etc.

The general principle illustrated in the Bogardus Social Distance Scale is that a set of attitudes may have a logical and/or empirical structure, which can be represented by a single number. This is the fundamental logic involved in all scaling.

The role of *pattern* is seen in the scoring of response patterns that seem illogical on their face. Suppose, a respondent was unwilling to let a convicted child-molester live in his or her country, city, neighborhood, block, and even next door—but agreed to have let one marry into the family. In terms of all but one of the indicators, the respondent appears to have extremely low tolerance for convicted child-molesters. Perhaps the respondent in question, however, has such an ideological commitment to letting one's children marry who they want that he or she would grimace and agree to letting the child-molester marry into the family. That response, then, would not represent tolerance toward child-molesters as much as commitment to freedom in mate-selection. In such a case, scoring the person 0 points—for no tolerance—rather than one point would seem a more accurate portrayal of their level of tolerance.

The Bogardus Social Distance scale has the quality of *ordinality*: a score of 2 represents more tolerance than a score of 1, and a score of 3 represents more tolerance than a score of 2. Ordinality is one goal of any index or scale, and the Bogardus Social Distance scale virtually assures the quality of ordinality.

Another goal—more difficult to achieve—is the creation of *equal intervals* between the scale positions. Thus it cannot be said that the distance between 0 and 1 on the Bogardus Social Distance scale is the same as the distance between 1 and 2. The achievement of equal intervals was addressed by L. L. Thurstone and his colleagues.

4. Thurstone Scaling

As seen in the case of the Bogardus Social Distance Scale, the indicators of a given variable can differ from one another in terms of *intensity*: some indicate a stronger degree than others. This phenomenon is not limited to social distance. For just about any variable, there are mild and extreme indicators of it. For example, the view that 'A woman should only be permitted to have an abortion in the case of rape or incest' represents a mild degree of anti-abortion sentiment in comparison with the view that, 'Physicians who perform abortions should be given the death penalty.'

L. L. Thurstone (1931) developed a technique for systematizing the differences in intensity that exist among the several indicators of a variable. His procedure began with the creation of a great many indicators (for example, 100), such as the two presented above. These were then presented to a panel of experts (e.g., PhD researchers specializing in studies of the variable in question) with instructions to score each item on a scale of, for example 1 to 11.

Once each panelist had scored each item, Thurstone then reviewed their scoring to identify items they had agreed on. Those items that produced disagreement among the panelists were discarded. Among those the panelists scored consistently, some were picked to represent each step on the scale: one or more items the panelists had agreed were 1s, items agreed to be 2s, etc. The resulting set of items were then administered to respondents.

Assume respondents were given a set of 11 items, one for each step in the intensity scale. Assume further that Respondent A agreed with all 11 items. In the creation of a simple index, such a person would receive a score of 11, representing an extreme case of whatever was being measured. If Respondent B disagreed with all 11, that person should receive a source of 0. Both respondents would receive those same scores on a Thurstone scale.

However, consider Respondent C, who agreed with 10 of the items, disagreeing only with the rather mild item rated 2 by the experts. In the creation of a simple index, such a respondent would receive a score of 10, representing the number of items agreed to. In Thurstone scaling, however, it would be reasoned that such a person must have idiosyncratic reasons for disagreeing with item 2, reasons that did not really reflect how they stood on the variable being measured, including misreading the item or checking the wrong box. In Thurstone scaling, Respondent C would be scored 11, based on the overall pattern of responses.

Or consider Respondent D, who agreed with only the most extreme item. Such a person would be judged to have reasons for that response that did not really reflect the variable in question—warranting a score of 0, based on the overall pattern of responses. Notice that this scoring procedure follows the same logic as discussed earlier in terms of Bogardus Social Distance scaling.

Thurstone scaling, like Bogardus scaling, results in the creation of *ordinal* scales: respondents scored 4 on the scale have a more extreme degree of the variable

in question than those scored 3. In addition, however, Thurstone scales may also qualify, arguably, as *interval* scales. A simple ruler illustrates this quality of equal intervals. The *difference* in length between an object two inches long and an object three inches long is the same (one inch) as the difference between an object thirteen inches long and one that is fourteen inches long.

An interval scale, then, is one which has a standard distance between adjacent positions on the scale. On an ordinal scale of prejudice, for example, a person scored 3 would be *more* prejudiced than one scored 2 and one scored 4 would be *more* prejudiced than one scored 3. On an interval scale, the prejudice of the person scored 3 would exceed that of the one scored 2 by the same *amount* as the prejudice of the person scored 4 would exceed that of the person scored 3. Because of the manner in which they were generated—asking expert judges to rate items along an interval scale and accepting only those items the judges agreed on—Thurstone scales are sometimes described as being comprised of 'equal-appearing intervals.'

Although Thurstone scaling nicely illustrates the logical purpose of scaling in general, it is seldom used. The reason for its disuse is logistical: it is too difficult and expensive to hire a large team of expert panelists to undertake the task of scoring hundreds of potential items. Moreover, once the task has been completed and items have been selected for a scale, the passage of time will cause a change in how certain of the items are regarded by people—and, hence, what agreement or disagreement with them implies. Thus, it is necessary to repeat the difficult and expensive procedure from time to time.

5. Likert Scaling

Rensis Likert is best known for creating a questionnaire format that remains very popular among survey researchers: illustrated most commonly by the response categories 'Strongly agree,' 'Agree,' 'Disagree,' and 'Strongly disagree.' There are three main appeals to such a format. First, it is convenient to present respondents with a number of statements on a variety of topics, following each with a set of boxes to check, labeling each column of boxes with one of the response categories listed above. Second, the set of responses can be remembered easily by respondents and they can easily understand how to record their responses to specific statements.

Finally, the Likert response categories have an undeniable *ordinality* 'strongly agreeing' clearly represents more agreement than simple 'agreeing,' which represents more agreement than 'disagreeing' which, in turn, contains at least more agreement than 'strongly disagreeing.' Notice, by contrast, that responses such as 'kind of agree,' 'more or less agree,' and 'agree to some extent' are ambiguous as

Table 2.

	Responses to Item 1			
	Strongly agree	Agree	Disagree	Strongly disagree
Average scores on the large index …	25	20	15	10

Table 3.

	Responses to Item 2			
	Strongly agree	Agree	Disagree	Strongly disagree
Average scores on the large index …	30	28	17	13

to the relative degree of agreement they represent. It would not be possible to arrange them in order of magnitude. And even if *you* have a clear view of how they differ, there is no assurance that all respondents in a survey would regard and use the terms in that same fashion.

Likert was interested in something more than just ordinality among response categories, however. Like Thurstone, he wanted to create *interval* measures. Rather than using expert judges, however, Likert looked for evidence of an interval quality among the patterns of responses given by respondents in a study.

Likert's *item-analysis* began in a similar fashion as the creation of a simple index. Items would be selected on the basis of face validity. Then respondents were given scores based on how they answered *all* those items. For simplicity's sake, assume that all the items were worded in the same direction: agreement meant prejudice and disagreement meant tolerance, for example. Respondents would be given 3 points for every 'strongly agree,' 2 points for each 'agree,' 1 point for each 'disagree,' and no points for 'strongly disagree.' If there were 10 items under consideration, this procedure would produce an index with scores ranging from 0 to 30.

The potential interval quality of each item was assessed by calculating the average scores (on the large index) for those who strongly agreed with the item in question, those who agreed, and so forth. Consider the case in Table 2.

In this example, the 'distance' between 'strongly agree' and 'agree' would appear—at least in terms of the simple index scores—to be the same as between 'agree' and 'disagree' and so forth.

By contrast, consider the possibility in Table 3. Here, there does not appear to be much difference in the overall views of those who strongly agreed and those who agreed, nor between those who disagreed or strongly disagreed—but there is a substantial difference between agreeing and disagreeing overall. Given the fact that responses to Item 2 do not correlate well with scores on the index overall, the conclusion must be that Item 2, despite its face

validity, does not provide a good measure of the variable in question.

Following a Likert item analysis, a scale might be constructed from among those items which appeared to have the quality of equal-appearing intervals. There are a number of specific techniques that might be used in the actual construction of such a scale.

6. Guttman Scaling

Guttman scaling, created by Louis Guttman, was probably the most common scaling technique used at the beginning of the 1990s. It has been widely used in sociolinguistics, especially in studies of language choice and shift, as well as of the creole continuum (see *DeCamp, David*). Like Likert scaling, it is based on an analysis of the empirical patterns to be observed in responses to items. It is more general than Likert scaling, since it can be applied to a variety of item formats—including Likert-type items.

To begin, the items considered for a Guttman scale are evaluated for intensity on the basis of how people responded. Consider two indicators of prejudice toward child-molesters: 'Do you think that child-molesters are different from other people?' and 'Do you think that all child-molesters should be executed?' Surely, more people would say yes to the first item than to the second. This is due to the fact that the first statement would have to be regarded as representing a very low level (if any) of prejudice, whereas the second is pretty extreme. Anyone who agreed to the second item would surely agree to the first as well, hence more would agree to the first one overall than to the second.

Guttman scaling would begin by examining the apparent degree of prejudice, for example, represented by each item—based only on the number who would be judged prejudiced by responses to that item. Next, responses to *pairs* of items are examined to determine whether those who agree to the harder one always (or almost always) agree to the easier one. In this fashion, a set of items would be selected appropriate to the creation of the scale.

A key to Guttman scaling lies in the scoring of response patterns. Scale scores are assigned in such a fashion as to permit the most faithful reproduction of original responses, called the *coefficient of reproducibility*. This is illustrated in Table 4.

Notice that patterns 1 through 5 are scored just as they would be in a simple cumulative index: one point for each indicator of the variable. More important, by knowing the scale score, all the specific responses could be faithfully reproduced. Knowing that a person was scored 3 for example, a '−' on Item 1 and a '+' on Items 2–4 could be predicted.

Look at Pattern 6, however. The only '+' is for Item 1, presumably the *hardest* item. In a simple index, such people would be scored 1, leading to the assumption that such people were '+' on Item 4 and

Table 4.

Item 1	Item 2	Item 3	Item 4	Pattern	Score
+	+	+	+	1	4
−	+	+	+	2	3
−	−	+	+	3	2
−	−	−	+	4	1
−	−	−	−	5	0
+	−	−	−	6	0
+	+	+	−	7	4
+	+	−	+	8	4
−	+	+	−	9	3
−	−	+	−	10	0 or 2

'−' on the rest. In each such case, then, two errors (Items 1 and 4) would arise if an attempt were made to reproduce the specific responses given by such people. By assigning a scale score of 0 in this instance, only one error would arise in reproducing the responses: guessing a '−' for Item 1.

A similar situation applies to Pattern 7. If such people were scored as 3, two errors would be made in reproducing the responses of each. Instead, by scoring them 4, only one error would be made for each such person. Patterns 8, 9, and 10 present other response patterns, indicating how each might be scored, so as to produce the fewest errors in reproducing the specific responses. Notice that in Pattern 10, either a score of 0 or 2 would produce the same number of errors (1), whereas an index score of 1 would produce two errors.

The *scalability* of a set of items is determined by calculating the *coefficient of reproducibility*. The total number of predictions that would be made (the number of cases times the number of items) is divided into the number of correct predictions that could be made on the basis of the scale scores. As a rough rule of thumb, a coefficient of 80 percent or higher is generally considered sufficient to justify the use of Guttman scale scoring instead of simple index scores.

There are numerous other techniques for creating composite measures, such as scales based on factor analysis or other such multivariate techniques. The foregoing examples should illustrate the logic of scaling techniques, however.

Small Group Research

W. S. Bainbridge

At the dawn of human history, before agriculture had made large societies possible, every human being lived within a small group of people that hunted and gathered together, sharing all aspects of their lives. Citizens of modern societies tend to belong to several small groups simultaneously, of different kinds and with different memberships, most making only slight demands upon the individuals who comprise them. The characteristic of small groups most important for the study of language is 'solidarity,' the extent to which the individuals who belong are bound tightly together into a social unit, and modern groups tend to be much lower in solidarity than the prehistoric hunting band. Stephen Wilson identified six dimensions of solidarity that together provide a useful rubric for considering linguistic aspects of small groups: interactions, norms, status structure, goals, cohesiveness, and awareness of membership.

1. Interaction

'Interaction' is defined as the process of mutual communication between individuals, often leading to interdependence between them. Among sociologists, there is some disagreement about the way that interaction creates a social bond. Members of the school of thought called 'symbolic interactionism' believe that humans have a natural hunger for language-encoded meaning, and that this alone is sufficient to explain why individuals who have communicated extensively with each other will tend to orient themselves toward each other's perceptions and desires. Scholars in the 'exchange theory' tradition consider the words exchanged between people less important than the rewards, and they hold that a person becomes bonded to another as a result of the valuable things (including verbally communicated information as well as material goods) that have been received. Certainly, individuals who do not interact cannot be said to be members of the same small group.

'Interaction process analysis', devised by Robert F. Bales in the late 1940s, is one of a number of techniques for studying interaction rates and patterns in small groups, employing highly trained observers who identify the smallest atoms of communication, 'unit acts,' and assign them to one of a set of 12 categories (Hare 1976). The simplest of the many other such techniques is that developed by Eliot D. Chapple around 1940, who divided all interaction into just two categories, action and silence. Using a device called the 'interaction chronograph' to help with the timing and data recording, Chapple would observe two-person interactions, focusing on when each person spoke.

Bales's system of categories inspired other researchers to invent their own schemes for identifying types of communication, based either on theories or on statistical analysis of data. Timothy Leary proposed a set of 16 psychological mechanisms that could be seen in interaction, including narcissistic reflexes (boast, act proud, narcissistically exhibitionistic) and docile reflexes (act in an over-respecting manner, docilely conform). Richard D. Mann's system of 16 categories was designed to analyze 'communicative acts,' defined as single speeches or bursts of sentences within which the expressed feelings are uniform, directed by a member of the group to its leader. Three of these are in the area of authority relations: showing dependency, showing independence, and showing counterdependency.

A vast body of research has been done with these social–psychological schemes for categorizing communicative acts, much employing Bales's system or adaptations of it. One can focus either on the kinds of unit acts the group primarily produces, for example, expressing solidarity versus hostility, or on the distribution of unit acts across the individual members. Then one can study such things as the way in which a group accomplishes a set task, the balance between task accomplishment and emotional gratification, the emergence of leadership, and the processes that establish norms.

2. Norms

'Norms' are authoritative standards of behavior, principles of right action binding upon the members of a group, including rules governing proper speech. As defined by George Homans (1950: 123), a norm 'is an idea in the minds of the members of a group, an idea that can be put in the form of a statement specifying what the members or other men should do, ought to do, are expected to do, under given circumstances.' The fact that a norm can be expressed as a statement does not mean that norms are learned primarily as statements communicated verbally, nor that they are encoded in memory as strings of words. In exchange theory, norms are learned through experiencing contingencies of reward and punishment, a process that can take place without use of language, as it does among pigeons and mice in psychological experiments. The extent to which all human norms are linguistic phenomena, not those concerning speech alone, remains an open question deserving scientific attention.

821

Some norms are very general, established by the society as a whole to cover a wide range of circumstances. An example is the biblical commandment, 'Thou shalt not take the name of the Lord thy God in vain.' Others are very specific, belonging to only a small group of people and concerning a limited range of circumstances. As reported by Homans, a particular group of nine factory workers attaching wires to telephone switching equipment had established a norm to call a man who made more than 825 connections an hour a 'rate-buster,' and someone who made less than 825, a 'chiseler.'

2.1 Norm Standardization

Among the most enduring themes of small group research is the way an individual's behavior changes as the result of belonging to a group, which can be conceptualized as the emergence and acceptance of norms. In the 1920s, Floyd Allport did many experiments on how people performed language-related tasks, to study 'social facilitation,' an increase in performance caused by the mere presence of other people. For example, research subjects were given a piece of paper with a single word written at the top and were asked to write as many disconnected words below it as they could in the time allotted. Most of them wrote more words while working in the presence of others, but they were judged to write words of a more personal nature while alone.

In another of Allport's experiments, subjects were given either mechanical tasks (such as crossing out vowels in newspaper stories), problem-solving tasks (writing statements disproving didactic passages from ancient philosophers), and judgment tasks (such as judging the relative pleasantness of a series of odors). For part of the time they did these jobs alone, and the rest of the time they were working in the presence of other research subjects. Interestingly, results depended upon the nature of the task. Subjects crossed out vowels more rapidly when working with others than when alone, and they wrote longer arguments in the group situation. However, arguments written while alone were deemed to be of higher quality. Judgments of the pleasantness of odors were less extreme when made in a group than when alone.

The most famous experiment in this tradition was done in the 1950s by Solomon Asch. Each research subject was placed in a group of six people, unaware that the other five were confederates of the experimenter. They were shown a series of cards, each with lines drawn on it, and asked to say which of three lines was the same length as a fourth. As the session progressed the confederates began unanimously giving the wrong answer, and the real research subjects, whose turn came last, were left in the quandary whether to accede to the judgment of the majority or to disagree. Much of the time, they expressed agreement with the confederates, but interviews with the subjects revealed that they often harbored private disagreements but conformed in what they said because they wanted to avoid appearing different from the rest of the group.

When participation in a group tends to reduce the extremes of individual speech or action, processes of standardization are at work. Homans noted that individuals who interact frequently tend to become similar to each other in their behavior and attitudes. Among the examples he offered, linking speech and action, was research done in a special test room at the Western Electric Company, where women were rapidly assembling electrical relays. The work required such concentration that the women could converse with only their nearest neighbors. Analysis of output rates showed that women working next to each other had unconsciously learned to work at almost identical rates. In this case, conversation had unintentionally standardized work patterns, but frequent interaction also has the power to standardize speech itself.

In the early 1960s, social psychology experimenters reported a phenomenon they called the 'risky shift,' in which research subjects accepted greater risks when they were making decisions in groups than when they were deciding alone. Later research found that some decisions were made more cautiously by groups than by individuals. This led to the realization that a group's norms are not simply the average or sum of the wishes of the individuals who constitute the group. Under a variety of circumstances, extreme norms of one kind or another may emerge from the complex web of social interaction in groups of high solidarity.

When a group of people who work closely together is under great stress, extreme pressures toward uniformity of opinion may arise. Irving Janis has called this 'groupthink' and argued that it often leads to very bad decisions. Members limit their discussion to but a few of the many alternatives open to them, fail to admit disadvantages of the course they have chosen or advantages of courses they have not initially considered, and avoid obtaining information that might provide a more realistic basis for evaluation. They show great interest in facts and opinions that appear to support their plans, and they ignore contrary data. They fail to deliberate possible barriers to success and are unprepared to deal with them when they arise. Individuals within the group who disagree are either excluded from the discussion or voluntarily suppress their own reservations. Among the examples of groupthink analyzed by Janis are the discussions in the advisory cabinets of American presidents Kennedy and Johnson that led to an abortive invasion of Cuba and to costly prolongation of the Vietnam War.

2.2 Communication Norms

Susan Shimanoff has suggested that there are seven types of communication rules established by small groups, each specifying desired behavior for one part of the following: (a) who says; (b) what; (c) to whom; (d) when; (e) with what duration and frequency; (f) through what medium; and (g) by what decision procedure. Formally constituted committees often have elaborate rules concerning who is 'speaker' or who 'has the floor,' but almost all groups possess habits and expectations about who will speak under a specified set of circumstances. Other norms define the limits of what shall be spoken about, for example, whether obscenities are prohibited or encouraged. In a weight-control group, Overeaters Anonymous, members may talk about food in generic terms ('refined carbohydrates,' 'junk food') but are enjoined from naming particular foods ('pizza,' 'twinkies'). The person to whom an utterance is usually addressed may be the designated leader, someone who has been temporarily recognized as having the floor, an individual member with a personal interest in the topic, or the membership as a whole. Groups differ in their preferences for each of these alternatives.

Some group norms concern who speaks when and what is said when. Groups may even differ in how they talk about these timing norms. Legend has it that a joint British–American committee of the military high command in World War II fell into deadlock because their dialects of English had opposite meanings for the term to *table* a topic. For the British, *table* meant to place a topic on the agenda, while for the Americans it meant to remove it from consideration indefinitely. Groups vary in the standards they set for duration and frequency of speech. Many legislatures follow elaborate procedures for allocating debating time, and even highly informal groups discourage individuals from 'hogging the floor' or 'talking out of turn.'

Although talking is the typical medium of communication in small groups, many in business and government also employ memos or even lengthy documents, perhaps to lay the basis for oral discussion or to provide a record of positions taken and decisions made. Norms concerning the proper medium may punish persons who write their messages in an oral group, or persons who fail to write when they are expected to. Norms concerning decision procedures are the political culture of the group, specifying whether a vote should be taken and how, informally conferring decision power on a few individuals, or requiring consensus of the entire group. Decision-procedure rules may exist to modify the six other types of communication rules, for example, requiring a two-thirds vote to end a filibuster. While it is easiest to illustrate communica-tion norms with examples from deliberative bodies that possess written rules, presumably every small group with some measure of solidarity possesses all seven kinds.

3. Status Structure

The word 'status' is often used to refer to a rank in a hierarchy, but in sociology it has a more general meaning, referring to any position in a social structure which defines a set of expectations for a person occupying it. In the USA the status of Supreme Court Judge is different from that of Senator, because they play very different roles in writing and interpreting legislation and they gain their positions through very different social processes, but the two may be of equal rank. Each status has certain rights and obligations, and satisfying the obligations attendant on a particular status is equivalent to playing the social role associated with it (see *Role Theory*). Informal small groups often lack explicit statuses, but as a group grows, a set of statuses tends to crystallize out while power differentials and division of labor become institutionalized. In modern bureaucracies, a formal structure of statuses is often outlined in an organizational chart and spelled out in detailed documents. But even in casual groups lacking any written records, members can usually say who occupies the leadership positions.

Among the most active fields for research on leadership in small groups is 'administrative science,' the study of effective and efficient management of businesses and other formal organizations. Like many other applied fields which lack clear criteria for evaluating the truth of ideas, administrative science is highly susceptible to fads, and many of its most popular notions about language and communication are based on rather shaky scientific foundations. One of the hottest continuing debates is the degree to which managers should share information and decision-making responsibilities with subordinates.

In 1960, Douglas McGregor distinguished two management philosophies he called 'theory X' and 'theory Y.' Theory X managers believe people are not to be trusted, so they keep close watch on their subordinates, avoid sharing responsibility and information with them, and are traditional authoritarian bosses. This means they tend to give detailed and complete instructions to their subordinates, setting explicit standards for performance in achieving the management-defined goals which they monitor with formal statistics. Theory Y managers, in contrast, believe their underlings can generally be trusted with responsibility, so they share more information and create a work environment in which people can best meet their own personal goals by working hard for

the goals of the organization. Thus they give only general instructions, depending upon the subordinates to work out details, employing group discussion and informal verbal feedback to maintain work momentum.

Clearly, these are two competing quasipolitical ideologies—authoritarianism vs. egalitarianism—and McGregor was probably asserting his own values rather than reporting scientific findings when he claimed that theory Y was more effective. In recent years, this belief has resurfaced many times with many labels (Tubbs 1988). David Bradford and Allan R. Cohen urge managers to be 'developers,' that is, to assist their subordinates in growing as human beings and to give them considerable freedom to solve problems in their own way. Among the paradoxes of the developer approach is the belief that managers increase their own power by giving subordinates greater powers.

Theory X is comparable to Machiavellianism, the philosophy of Niccolo Machiavelli, and some researchers have used a Machiavellianism scale developed by Richard Christie to measure this untrusting style of management. Among the scale's items are several maxims concerning speech: 'Never tell anyone the real reason you did something unless it is useful to do so.' 'It is wise to flatter important people.' Machiavellians are expected to agree with these two statements, and to disagree with the proposition, 'There is no excuse for lying to someone else.' The theory X manager may not be a liar, but he does not expect other people to do what they say, and he monitors their actual behavior closely rather than trusting their words.

In contrast to these one-sided analyses, 'contingency theories' note that different styles of leadership are effective under different conditions. Paul Hersey and Kenneth Blanchard stress the importance of the degree of maturity of the followers in determining which of four kinds of management is appropriate: telling, selling, participating, and delegating. People who are both unable and unwilling to take responsibility must simply be *told* what to do. Subordinates of slightly greater maturity must be *sold*; they still need directive management but will be more fully committed to the task if they can be convinced to 'buy into' desired behaviors by the explanations of their boss. A nondirective 'participating' style will help motivate persons of moderate to high maturity, through effective two-way communication with the leader. Finally, tasks can simply be 'delegated' to fully mature subordinates who can be trusted to accomplish them without much direction, explanation, or two-way communication with the manager. This analytic scheme expands the two categories of McGregor's analysis into four, and avoids the unwarranted assumption that one is best under all conditions.

John Kotter, Leonard Schlesinger, and Vijay Sathe note that management occasionally need to change the organization they direct in a significant way, and that several tactics may be used to overcome employees' resistance, depending upon a variety of factors. When speed is essential and the managers possess considerable power, the right tactic may be coercion, but this can leave a residue of anger. Education/communication may be the right approach when resistance to change is based on lack of correct information, and once persuaded, people may actively help implementation of the change; however, this tactic is typically quite slow. Negotiation is best in situations where one group is bound to lose as a result of the change, and where they have power to resist. Tactical schemes like this are Machiavellianism of a higher order, because communication rules are treated as contingent upon the manager's analysis of the most effective way to control subordinates, not determined by invariant norms. Honesty is treated as only one of a number of good policies, the best only under certain circumstances.

4. Goals

In many cases, a group is a set of people with a common goal, but other groups may never have defined a goal, and the members of many groups may have personal goals that conflict with those of other members. Goals vary from the most specific, to the most general, what are often called values. High-solidarity groups tend to have many defined goals rather than just a few, a consensus on what the goals are rather than a disagreement, cooperative rather than competitive goals, and motives oriented toward their group rather than each member being concerned only with himself or herself. Many groups define their goals at the moment they come into being, for example, business and special interest clubs, but others experience a sometimes lengthy process of searching for goals.

Albert K. Cohen has analyzed the way 'mutual conversion' can create a group and give it distinctive goals, if a number of individuals with similar problems of social adjustment come into communication with one another. This takes place in tiny, even imperceptible steps, as one individual expresses a hope or plan and receives positive feedback in the form of similar hopes and plans from the others. Cohen believed that all human action is an ongoing series of efforts to solve problems, but he focused on the specific frustrations of lower-class adolescent boys who experienced repeated failures to meet the standards of middle-class culture, especially in school where particular kinds of verbal facility are demanded. Unable initially to express their frustrations

to each other, these boys will congregate in groups and begin to share various escapades in which they explore alternative, even deviant patterns of behavior. Together, they gradually redefine conventional standards as bad and erect a new set of standards which they can successfully meet. The result is a delinquent gang (see *Subcultures and Countercultures*). Mutual conversion can occur with many other kinds of group, and Cohen's analysis sensitively describes how tentatively the parties may grope their way to a consensus.

Similarly, Richard Cloward and Lloyd Ohlin argued that youth whose attempts to achieve the goals valued by society have been thwarted may collect into delinquent gangs that seek these or other goals by deviant means. In theft or vice can provide the money and status desired by these adolescents, they will create a 'criminal' gang. But for many of them, success will be as hard to attain through crime as it was through attending school, and they will be forced to set new goals, such as violent defense of their city block against other gangs, and they will become a 'conflict' gang. If beaten in this attempt, or if the members of the adolescent group lack the strength and skill for fighting, they will become a 'retreatist' gang, descending into drug addiction or losing a sense of personal and collective goals altogether.

George Homans explained that groups exist as a means by which members can cooperatively extract resources from the environment and defend against threats. In meeting these goals, the members develop what Homans called the 'external system,' a set of social relations that allows the group to survive in its environment. As members interact, however, they come to value each other not merely as means for coping with the environment, but for their own sakes and for the social and emotional rewards they can provide each other. Thus arises the 'internal system' of the group, social relations not primarily conditioned by the external environment, often purely verbal in nature, such as pleasant conversation and joking. While the internal system can take on a life of its own, it will eventually die if the external system fails to achieve its goals.

Parallel to the different goals that groups may have are the various goals researchers pursue in studying them. Sociologists by the score have examined delinquent gangs, both because deviant behavior provides a certain journalistic excitement and because the conventional society feels gangs are a serious problem. Those who have studied psychotherapy groups typically had the goal of evaluating or promoting the particular brand of therapy, and research in business and industry sought information about how to increase profitability. The artificial groups created in social psychology laboratories contributed to the development and testing of often rather narrow theories about group dynamics.

5. Cohesiveness

'Cohesiveness' is sometimes defined as the degree to which members are attracted to their group, but a definition that has been especially productive for research is the degree to which members are tied to each other by social bonds. Sociometry (see *Sociometry*) is a set of methods for measuring the social bonds within a group, whether by simply asking each individual which others he or she especially likes or by observing which persons tend to interact most with each other. If a group is high in solidarity, its members will be connected by strong social bonds, and many researchers have used cohesiveness as a synonym for solidarity.

One language-related field of research that has made especially good use of analysis in terms of social bonds is the sociology of religion (Stark and Bainbridge 1985). A popular slogan holds that 'the family that prays together stays together,' and many studies have shown that religious belief and practice are powerfully connected to the strength and structure of social relationships. Kevin Welch assessed the role of interpersonal bonds in sustaining commitment to orthodox beliefs among members of mainline denominations in the United States, finding strong positive correlations between various measures of orthodoxy and the proportion of one's best friends who are members of one's own religious congregation. Also, the greater the number of nonchurch organizations and clubs the person belonged to, the lower his or her orthodoxy.

Members of highly cohesive religious groups are more likely than others to proselytize, to pray, and to profess their faith with confidence. Rodney Stark examined the effects social context had on religious experiences, moments when the individual believed he or she had a personal encounter with the supernatural, finding that people who had such experiences were highly concentrated among those whose closest friends were members of the same religious group. Thus, conversations with God are facilitated by communication with fellow believers; or, unusual psychological states are more likely to be defined as religious in nature if the person belongs to a cohesive group that wants to interpret them that way. But it is also true that religious groups that provide many shared spiritual experiences, whether formal rituals or informal gatherings, tend thereby to create a sense of communion and thus cohesiveness between members.

Among the best explanations of conversion to small, radical religious groups—'sects' and 'cults'—is the process of recruitment through social bonds. The model that has received the most attention was

proposed by John Lofland and Rodney Stark, and it has guided many subsequent research studies. Combining social bond analysis with other factors, it has seven steps.

(a) The person must suffer enduring, acutely-felt tensions which derive from a discrepancy between the person's current life conditions and those he deeply desires.

(b) The person possesses a religious problem-solving perspective, a way of understanding life events that defines their causes in supernatural terms.

(c) Dissatisfied with the help received from a current religious group, the person defines himself as a religious seeker on a quest for a new religious group.

(d) The person encounters the sect or cult at a turning point, which may combine a period of weak social attachments with the termination of old lines of action, as may come with divorce, school graduation, or a new job.

(e) A strong emotional social bond develops with members of the radical religious group.

(f) Emotional social bonds with nonmembers are lost, weakened, or neutralized by being defined as irrelevant to the person's needs at the moment.

(g) Intensive interaction with members of the group inculcates its beliefs and turns the person into a committed member ready to recruit others to the new faith.

This analysis places great emphasis on social interaction with members of the group. An alternative theory, which has been used to explain conversion to various political creeds as well as religious faiths, postulates that converts are emotionally vulnerable to ideological appeals, because they suffer intense personal deprivations, causing unendurable frustration. The person will then encounter an ideology that explains this suffering in ways flattering to the sufferer and offers an apparent solution to the person's problems. The Lofland–Stark theory incorporates these ideas, but argues that they are not enough, and subsequent research has supported this assertion. Apparently it is not sufficient to hear 'the word.' Rather, one must develop social bonds with current believers who draw one into a small, like-minded group, and only then does one listen receptively to the word and eventually accept it. In general, membership in a group precedes acceptance of its beliefs and practices.

6. Awareness of Membership

Charles Horton Cooley wrote on *primary groups*, those characterized by intimate face-to-face association, and said membership in one 'involves the sort of sympathy and mutual identification for which *we* is the natural expression.' The 'sense of we-ness' or 'we-feeling,' as it has been called by sociologists, is a variable that is strong in some small groups but weak in others, measurable in part by members' use of the first person plural in talking about it. Another marker of significant we-feeling is the possession of a name for the group.

Names, of course, tell us much about the image members have of their own group and how they want outsiders to regard them. 'Hell's Angels' must be both terrifying and important. Members of the 'Cornbelt Lapidary and Geological Society' profess a rather specialized set of harmless interests and live in an informally defined region notable for growing corn. Churches that call themselves 'Christian Science,' 'Divine Science,' or 'Religious Science' are apparently modern creations that seek some of the prestige that science has had in recent years.

Rodney Stark studied the names adopted by novel American religious cults in different periods, finding that the proportion with innocuous, Christian-sounding names was nearly twice as high early in the century as it was after 1950. Among some of the older names that apparently provided camouflage to protect the cults from public outrage were Universal Christ Church, Liberal Catholic Church, and Congregational Church of Practical Theology, actually deviant cults in the spiritualist, theosophical, and psychic traditions, respectively. More recently, cults have been happy to be known publicly by names such as Enchanted Moon Coven or Church of Satanic Brotherhood, a sign that society is far more tolerant of religious deviance than formerly.

As Stephen Wilson explains, many social psychologists have equated awareness of membership in a group with morale, but morale has proven very difficult to measure. If one simply asks people whether they belong to a highly prestigious group, many will profess membership who do not seem really to belong. A group toward which people orient their action and which sets standards for their behavior, even if they are not in all the senses discussed here members of the group, is a 'reference group.' Actual membership in a small group involves all six of the dimensions of solidarity, not awareness alone. Calling oneself a member is not enough.

The research on small groups is vast; A. Paul Hare's 1976 bibliography lists fully 6037 publications, but he ignores most of those done by sociologists and others on natural groups in the field, concentrating instead on laboratory experimental studies. A considerable fraction of this scholarship concerns language, but few of the authors have an awareness of membership in the profession of linguistics. Nonetheless, students of language would have much to learn from examination of small group research; many of these studies should be renamed linguistic, and small group researchers would benefit from realization of the contributions that linguistics could make to their work.

Sociometry
W. S. Bainbridge

Research frequently compares features of language in such social groups as socioeconomic classes, ethnic subcultures, and political–geographic units, yet in the modern world few social barriers are linguistically impermeable, and there is good reason to doubt the logic of dividing human beings into separate speech communities. An alternate research strategy is to map the network of social relations and communication channels that link individuals, and to measure the degrees of linguistic difference that occur at various distances across the social structure that they define. The classic method of sociometry was developed by Jacob Moreno, and a host of related techniques for measuring social relationships have been developed in recent years.

1. Measuring Social Structure

Moreno's method was designed to chart relationships in an identifiable small group, for example, the children in a particular schoolroom or the workers in a particular industrial team. The researcher might ask each of the children to write his or her name at the top of a piece of paper, and to put the numbers 1 through 4 in a column. After the number 1, the child was supposed to put the name of his or her favorite playmate among the other children in the room. After the number 2 would come the second-favorite playmate and so on until the name of four other children were listed in order of descending preference.

Research on adults typically employs several such 'sociometric' questions. The members of a work group might be asked to make one list of the fellow members they would seek out for advice on their work, and a second list of the members they most enjoy spending social time with away from work. The classical method for analyzing and displaying the data from a sociometric question is to draw a 'sociogram,'

a diagram in which people are represented as dots and sociometric choices as lines connecting them. A pair of such sociograms can be seen in Figure 1, based on actual research on a small printing company, but giving pseudonyms to the seven persons whose first two sociometric choices are charted.

The actual set of social relationships represented by the sociogram is a 'social network.' A person chosen by none of the others in the group is called a 'social isolate,' while a subgroup who name each other but are not strongly connected to others in the total group constitute a 'clique.' Divisions between cliques, crossed by relatively few lines in the sociogram, are 'cleavages.' In terms of work-related advice, there are three social isolates at the printing company: Dora (secretary), Gary (pressman), and Frank (apprentice pressman), but no complete social isolates emerge in the analysis of social relations away from work. The owner, Albert, is central to communication patterns in both diagrams, as are Bob, the head pressman, Edgar, a pressman, and Connie, one of the two secretaries. A moderate cleavage appears for social relations, and the group of seven is centered on a *triad* (Albert, Bob, and Connie) and a *dyad* (Frank and Gary). During the 1980s, a host of mathematical procedures have been developed for systematically measuring these and other features of sociometric data.

2. Research Approaches

When employed in linguistic research, sociometry provides information about social structure that must be coordinated with some features of language. In principle, different features of language may be associated with different kinds of social relations. At the printing company, it would be expected that the 'mutual pairs' who choose each other for

work-related advice to be very similar in their use of work-related language, such as printer's jargon. However, mutual pairs in the diagram for social relations away from work might be more similar in their use of terminology for leisure activities.

Harry Crockett and Lewis Levine used sociometry to understand variations of pronunciation of postvocalic *r* and the present participle ending *-ing*, in a small community in the Southern United States. Pairs of friends tended to be similar in their pronunciations, when compared with pairs of individuals chosen randomly from the respondents to an extensive survey. One limitation of Moreno's original methods is that they ideally require complete data from all the individuals in the group, a criterion that is very difficult to achieve with anything but the smallest groups and impossible with a random sample of a large population. By focusing on pairs of individuals, the researcher may get very much the same results as if working with a far more costly complete sociogram.

Theories can be tested with even more fragmentary sociometric data, based on individuals' replies to questions about their social relations but not attempting to coordinate data from different respondents. In a study of vernacular language loyalty in working-class sections of Belfast, Lesley Milroy and Sue Margrain (1980) were interested primarily in whether the respondent belonged to a closed, cohesive, local network, or possessed social relationships that spread out more widely both socially and geographically. Questions about the residential proximity of relatives, sharing social time with work mates, and having work mates who lived nearby distinguished persons who were tightly bound into local networks from persons more cosmopolitan in their social relations, and substantial differences of pronunciation were found between these two groups.

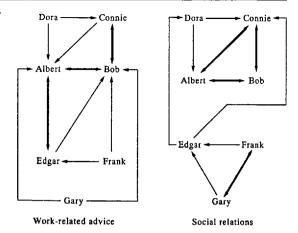
Potentially, any feature of language can be studied sociometrically. One of the more ambitious methodological developments is Kathleen Carley's (1986) 'frame technology' for comparing individuals' definitions of concepts. Rejecting the notion that individual differences in definitions can be captured adequately through synonym lists or other traditional methods, Carley has relied on expert systems


Figure 1. Sociograms of a small printing company.

techniques from the field of artificial intelligence. First, she conducted interviews with respondents, getting them to associate numerous qualities with the concept in question. The data were then put into a set of special computer programs that charted respondents' conceptual 'frames' as networks of definitional connections. Finally, measures of the similarity of respondents' frames were compared with sociometric data. In such research, the concept of network is central to all parts of the analysis, because definitions are seen as networks of concepts, shaped by the social networks revealed through sociometry.

Statistics in Sociolinguistics
D. Sankoff

1. Introduction

Many areas connected with sociolinguistics in which quantitative data play a role, have seen the application of statistical methods, both traditional (experimental design, sampling, estimation, hypothesis testing) and heuristic (clustering, scaling). Some of these are discussed in other entries (see *Social Psychology; Sociometry; Attitude Surveys: Question–Answer*

Process; Scaling; Multidimensional Scaling). It is within variation theory, however, where social considerations are most intimately connected to grammatical questions, that a specifically sociolinguistic protocol for statistical analysis has been developed and widely adopted. This article will survey the justifications for this approach and sketch how it has been applied to various types of linguistic problems.

2. Epistemological Concerns

Linguistics is unique among scientific disciplines in that its practitioners generally do not require statistical methodology and are not constrained by statistical criteria of validity. Linguists traditionally agreed that the grammatical structure of a language consisted, in large measure, of discrete entities or categories whose relationships and co-occurrence constraints were qualitative in nature and shared by all speakers in the speech community. These structures could then be deduced by analyzing and comparing test utterances elicited from, or intuited by, any native speaker of the language (e.g., linguists serving as their own data source), without need for any statistical apparatus.

It is only since the groundbreaking work of William Labov (see *Labov, William*) in the late 1960s that any concerted attempt has been made to investigate questions of central interest to linguistic theory using statistics (Labov 1969). He made credible to many linguists the idea that two or more different articulations of a given phonological form may occur in the same word or affix, in the same contexts, without affecting the denotational value (referential meaning) of a lexical item, or the syntactic function of an affix or particle. Which form will occur at a given point in time can only be predicted in terms of a probabilistic model, whereby the effects of the linguistic and extra-linguistic context can be ascertained with accuracy, but where the output of the analysis remains just a probability. The choice of form always contains a component of pure chance, though this is precisely delimited.

Alternation among forms also occurs at the syntactic and lexical levels, though the scope of syntactic equivalence and lexical synonymy are the subject of much debate. The distributionalist tradition of linguistics is based on the uniqueness of the form-function relationship, something variationism rejects as an unwarranted assumption. Analysts may well identify, *upon reflection*, differences in connotation among synonyms or among competing syntactic constructions, whether in isolation or in context, but there is no reason to expect these differences to be pertinent every time one of the variant forms is used. Indeed, underlying the study of syntactic variation within a framework similar to that of phonological variation is the hypothesis that for certain identifiable sets of alternations, these distinctions come into play

neither in the intentions of the speaker nor in the interpretation of the interlocutor. We say that 'distinctions in referential value or grammatical function among different surface forms can be neutralized in discourse' (Sankoff 1988). This is the source of the phenomenon of 'equivalence' and the justification of the syntactic variable that have so preoccupied sociolinguists. It is the fundamental mechanism of non-phonological variation and change.

The formal models of grammatical theory have discrete structures of an algebraic, algorithmic, and/or logical nature. Such structures often involve sets of two or more alternate components, such as synonyms, paraphrases or allophones, which the analyst may determine to be carrying out identical or similar linguistic functions. By allowing a degree of randomness into the choice between such alternates, the grammatical formalisms are converted into probabilistic models of linguistic performance susceptible to statistical study (Cedergren and Sankoff 1974).

3. The Sample

Language modeled as generated by probabilistic grammars is most appropriately studied by the data of natural discourse: sustained fluent sequences of connected utterances. The construction of a sample of natural speech is very different from sampling for sociological questionnaire administration, for psychological experimentation, or for educational testing, since one generally cannot predict when or how often the linguistic phenomenon under study will occur in the flow of conversation. Hence the sample usually involves relatively few speakers (20 to 120), carefully chosen to represent the diversity of linguistic behavior within the community being studied, with a large volume of material tape-recorded from each speaker. This material is transcribed in computer-accessible form, and is systematically scanned for occurrences of the words, sounds, or grammatical structures of interest. Usually, the same data set (the 'corpus') can be used for many different studies, since it is representative of all the structures and usage of natural speech (Sankoff and Sankoff 1973).

4. The Research Question

Corpus research (see *Corpus Linguistics and Sociolinguistics*) may provide examples or counter-examples as an adjunct to theoretical arguments. But what is equally important, and often more so, are quantitative patterns of occurrence relatively inaccessible to introspection or even testing methodology. Regular, complex relationships may exist at the quantitative level among a number of structures, but upon introspection, all we can say is that they are all simply 'grammatical.' Quantitative regularities

829

may be vaguely guessed at through introspection, but may not be characterized with anything like the precision with which intuition-based methods can establish categorical relationships.

The quantitative facts are not minor details of linguistic behavior. Universal hierarchies and co-occurrence constraints not manifested in terms of grammaticality versus ungrammaticality for a given language are nonetheless often present in clear and well-developed form in usage frequencies. The classical examples are constraint hierarchies for the expression of certain allophones (or the application of optional phonological and morphophonological rules), but it is also true of syntax, in the study of variable rule order, optional movement or deletion rules, and in preferences among semantically or functionally equivalent phrase structures.

Moreover, it is these variable aspects of grammatical structure which are always the locus of linguistic change (see *Sociolinguistics and Language Change*). Change virtually always requires a transitional period, often very lengthy, of variability, competition among structures and divergence within the speech community. The detailed nature of linguistic change and of its synchronic reflex—dialect differentiation—cannot be understood without coming to grips with quantitative relationships.

The tools for studying these relationships are necessarily very different from those used in theoretical linguistics. Frequency counts of forms in contexts are not just quantitative refinements of judgments of grammaticality and have even less to do with acceptability. Counts of 0 percent are analogous to judgments of ungrammaticality, but not identical to them. Non-occurrence does not necessarily indicate a prohibited form. It may simply be the result of a complex combination of features, which could be perfectly grammatical but unlikely to appear in any reasonably sized corpus. Conversely, intuitively ungrammatical forms may appear systematically and at a non-negligible rate in spontaneous speech through the interaction of the grammatical facility with processing constraints.

5. The Linguistic Variable

The key concept underlying variationist sociolinguistics is the 'linguistic variable.' A well-studied example is the pronunciation or deletion of syllable-final /s/ that characterizes most varieties of Caribbean Spanish. Another example, from spoken English, is the copular verb *be*, which occurs as the contracted variant (*John's a doctor, we're coming, I'm at home*) or the full variant (*John is ... we are ... I am ...*). A third example involves *th*, as in *this* and *think*, which usually have an interdental fricative pronunciation, but which are also pronounced at least occasionally by speakers of most varieties of English as stops (*dis, tink*). A fourth example is the alternation of future

and periphrastic future tenses (*You will hear about it* versus *You are going to hear about it*).

6. The Model

The choice of one variant or another of a binary linguistic variable can be heavily influenced by a wide range of factors, including the phonological and syntactic context in which it occurs, the topic of conversation, the degree of situational or contextual formality, idiosyncratic tendencies of the speaker, and the identity of the hearer(s). These factors, however, usually cannot account for all the variability in the data, and so a probabilistic model is set up to evaluate their influence:

$$\log p/(1-p) = a_i + a_j + \cdots + a_k \qquad (1)$$

where p is the probability that a particular one of the two variants will be chosen and $1-p$ the probability of the other, in the context containing linguistic or extralinguistic features labeled $i, j, \ldots, k$. In this 'logistic-linear' model a_i represents the effects on the choice of variant of feature i in the context of the variable. If p represents the probability of contraction in the example of copula given above, and if feature 1 and feature 2 indicate that the sound preceding the copula is a vowel or consonant, respectively, while feature 3 and feature 4 indicate that the grammatical category following the copula is an adjective or a noun phrase, and feature 5 and feature 6 indicate informal and formal speaking styles, then a_1, a_3, and a_5 will be high (each ca. 1.0) while a_2, a_4, and a_6 will be low (each ca. -1.0). Thus the *is* in *John is the leader*, as uttered in a formal context is far less susceptible to contraction ($p = 0.05$) than the *are* in *You are bad*, spoken informally ($p = 0.95$).

With sociolinguistic data, it is conventional to include one feature, called the mean or corrected mean, in formula (1) for all contexts. The other features fall into disjoint 'factor groups.' Usually one or another feature from each factor group appears in every context, and no two features from the same factor group can co-occur. The mathematical structure of (1) requires us to impose some constraint on the feature effects within each factor group, such as that the sum of the effects be zero. Without this the mean cannot be estimated uniquely.

7. The Data

For statistical analysis, the speech sample is scanned for occurrences of one or the other variant of a variable, and each occurrence is recorded along with the features (or factors) present in the context. Each observed combination of contextual features is considered to define a data cell for the analysis, where the number r of occurrences of one of the variants, compared with the total occurrences n in the

cell, is assumed to be a binomial random variable with parameters n and p.

Because the distribution of the data among the cells cannot be controlled when a natural speech sample is used, and because many different factors may influence the probability p, the final 'design' is often a high-dimensional array with many or even most of the possible cells empty ($n = 0$), and the data is distributed very unevenly among the others. Estimation methods based on sum-of-squares approximations such as multiple regression and analysis of variance are thus inappropriate and the parameters must be estimated using exact maximum likelihood methods. Many statistical computing packages have the capability of carrying out this type of analysis, although most of the linguistic work has made use of one or other version of the 'variable rule' program (Rand and Sankoff 1990, Robinson et al. 2001). Elimination of statistically irrelevant influences can be assured by a multiple regression type of analysis with a stepwise selection of significant factors. For example, in expressing future time in the French spoken in Montreal, if a verb is negated, this has a statistically very significant effect in reducing the use of the periphrastic future. Elevated socioeconomic status of the speaker is also a significant factor, while neither the nature of the subject of the verb nor the age of the speaker has a significant effect.

8. Detecting Heterogeneity

A major preoccupation in sociolinguistics is the degree of homogeneity of the speech community. Do all speakers in the community share a common model of type (1)—possibly involving a single parameter to account for individual differences—or might different individuals or different segments of the community each have a substantively different model of type (1)? A way of answering this question is based on a dynamic clustering procedure. An initial (random) partition into k groups of the speakers in the speech sample is made, followed by an estimation of the parameters in k versions of model (1), a separate model for each group. Speakers are then reassigned to groups according to which model they 'fit' best, using the likelihood criterion. Further iterations are carried out on the estimation and reassignment procedures until they converge. The significance of the analyses for each of $k = 2, 3 \ldots$ can be tested based on the increase in likelihood with the increase in k, compared with the number of additional parameters estimated.

Thus, in expressing an indefinite referent, Montreal French speakers fall into two groups according to how they vary between *on* 'one' and *tu* 'you.' In one group, speakers have a high rate of *on* usage in conveying proverb-like sentiments and in a certain class of syntactic construction while the other group

shares the former but not the latter (syntactic) effect (Rousseau and Sankoff 1978a).

9. Implicational Scales

Data on a linguistic variable are sometimes given as a two-dimensional array, where each row represents a different speaker or speech variety and each column represents a different linguistic or sociolinguistic context. In the simplest version, each cell of the table contains a 0 or a 1, indicating which of two variants of a linguistic variable is expressed by the given speaker in the given context. The problem is to re-order the rows and columns so that every row consists of a series of 0s to the left followed by a series of 1s to the right (i.e., no 0 is to the right of a 1 in a row) and every column consists of a series of 0s at the top followed by a series of 1's on the bottom (i.e., no 0 is below a 1 in a column), as in Table 1.

If an implicational scale can be established, it represents a highly economical representation of the how the set of speakers and the set of contexts are organized in terms of this linguistic variable.

It is not always possible to arrange data into an implicational scale, so various somewhat arbitrary measures of scaling have been proposed, to assess to what extent a data set is 'scalable,' based on the minimum possible number of 'scaling errors.'

In the general case, instead of 0s and 1s, each cell contains a fraction r/n, representing the successes divided by the total trials of a binomial experiment (or the uses of one of the variants divided by the total occurrences of the variable). The problem is then to find row and column permutations (or relabelings) such that in the relabeled matrix, r/n is nondecreasing along both rows and columns, as in Table 2. This type of analysis is of interest when in most cells $r/n = 0$ or $r/n = 1$, so that all except a few 'transitional' cells correspond to the 0s and 1s of the basic analysis.

It might seem that a logistic-linear model such as (2) would not seem capable of accounting for data which form an implicational scale since p could not be 0 or 1 for any cell as long as the speaker effect a and the row effect b are finite.

$$\log p/(1 - p) = a + b \qquad (2)$$

In other words, model (2) could only give an approximate account for nonvariable behavior (i.e., when $r/n = 1$ or $r/n = 0$). In properly defined maximum likelihood estimation for data such as those in Table 2, however, the estimates for a and b in (2) remain undefined, but the estimates of p in each cell are well defined, and can take on values 0 and 1 where the data predicts nonvariable behavior (Rousseau and Sankoff 1978b). This forms the basis for an integrated logistic-linear/implicational scale analysis, including a principled basis for

Table 1. Simple implicational scale depicting variant use (0 versus 1) in 5 contexts by 6 speakers.

	context 1	context 2	context 3	context 4	context 5
speaker 1	0	0	0	0	1
speaker 2	0	0	0	0	1
speaker 3	0	0	0	1	1
speaker 4	0	0	0	1	1
speaker 5	0	1	1	1	1
speaker 6	1	1	1	1	1

Table 2. General implicational scale depicting one variant's frequency r divided by total occurrences n of the variable.

	context 1	context 2	context 3	context 4	context 5
speaker 1	0/3 = 0	0/1 = 0	0/5 = 0	1/6	2/4
speaker 2	0/10 = 0	0/3 = 0	0/3 = 0	5/12	8/9
speaker 3	0/2 = 0	0/1 = 0	0/1 = 0	6/6 = 1	10/10 = 1
speaker 4	0/7 = 0	0/4 = 0	0/2 = 0	2/2 = 1	3/3 = 1
speaker 5	0/6 = 0	3/4	8/10	6/6 = 1	6/6 = 1
speaker 6	2/7	7/8	8/9	1/1 = 1	9/9 = 1

rejecting data which cause 'scaling errors,' since these data turn out to be outliers in terms of their extremely low likelihood under a maximum likelihood analysis of the data set (Sankoff and Rousseau 1979).

10. Rare Variants

Variation theory sometimes encounters a situation, especially in syntax, where one of the two variants is extremely rare, and may not even occur once in the entire corpus at hand. This variant may well represent an important phenomenon, however, such as an incipient change or a necessary condition of some other rare contextual feature. Examples of the rare variant may only be collected through what is effectively participant observation, writing down sentences as they are heard in daily conversation, on the radio or television, or read in the written media.

We then effectively have two corpora, the conventional one containing no examples of the rare variant but sufficient examples of the usual variant distributed among a sample of contexts, and the new corpus containing exclusively examples of the rare variant, presumably in a representative sample of the contexts in which it occurs. Though it may seem somewhat counterintuitive, variable rule analysis based on formula (1) can be carried out as normal on the combined data set, as if all the occurrences originated in the same corpus (cf. Bishop 1969). The only difference is that the estimate of mean or corrected mean has no meaningful interpretation, since this would depend strongly on the (unknown) total amount of conversation from which the rare variant examples were extracted. The feature effect estimates, however, have their normal interpretation and are not affected by the dual origin of the data.

11. Multiple Variants and Rule Order

In the preceding sections, we have only discussed choice variables, which are dichotomous, although the factor groups could contain any number of factors. There are many cases, however, where a linguistic choice may be perceived as involving three or more alternatives simultaneously. Generalization of the mathematical treatment to this context offers no conceptual difficulty, only a number of complications in the formulae.

For example, consider the case of three variants A, B, and C, with probabilities p, q, and r in a given context. The logistic-linear model becomes:

$$\log(p/q) = a_i + a_j + \cdots + a_k$$
$$\log(q/r) = b_i + b_j + \cdots + b_k \qquad (3)$$
$$\log(r/p) = c_i + c_j + \cdots + c_k$$

Actually, the third equation is equivalent to the sum of the other two, and hence is redundant. In general, if there are n variants, then $n - 1$ equations suffice to define the model.

When there are multiple variants, it is not always clear whether they should be considered as having been generated simultaneously, or whether certain distinctions among the variants are decided before others. This part of the classical problem of rule ordering can be studied through variable rule analysis. The other part of the problem, the question of what forms underlie what others, cannot be approached through statistical analysis of conditioned choice data.

For example, consider a hypothetical variable with four surface forms (variants 1 through 4). Mathematically speaking, there are 184 ways of generating these by different rule order schemes from a common underlying form, though many of these may be implausible. Two schemes are depicted in Fig. 1.

The first rule in scheme (a) can be analyzed by a two-variant variable rule, since we know how many times in each context the choice was made to rewrite (the number of surface occurrences of variants 2, 3, and 4) and how many times it was not (the number of occurrences of variant 1). Similarly, the choices represented by the second rule can be analyzed using the number of variant 2 versus the number of 3 and 4. And the third rule is based simply on the number of 3 versus the number of 4. In scheme (b), the two-pronged rule represents a simultaneous three-way choice between variants 1, 2, and 3, and can be analyzed using the number of variant 1 versus (2 and 4) versus 3.

The likelihood of each of the 184 schemes can be calculated as the product of the maximum likelihoods of the individual choice processes represented by its rules. We can then invoke the principle of maximum likelihood to infer the best scheme. Suppose that analysis of data showed that (b) in Fig. 1 is the most likely scheme. Then there would be at least five other schemes, such as the two in Fig. 2, which must have exactly the same likelihood, since they imply exactly the same choice processes. They differ only according to which forms underlie which others.

The implication of this equivalence for the problem of rule ordering is that this problem can be decomposed into two aspects. One is the identity of the underlying form or, more generally, which variants give rise to which other, and the second aspect is the most likely arrangement of the variants into a treelike, or hierarchical classification, of which there are only 26 different possibilities compared to the 184 schemata in the example. The data on variant occurrences in context do not bear at all on the first aspect, but do allow us to use statistical means, namely the comparison of the likelihoods of the different schemata, to infer the hierarchy. Thus only the order in which the distinctions among subsets of variants are drawn can be studied statistically, and not the question of underlying forms.

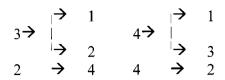
Figure 1. Rule order schemes: (a) some occurrences of underlying variant 1 rewritten as 2, then some of these 2 rewritten as 3, then some 3 rewritten as 4; (b) some 1 rewritten as either 2 or 3, then some 2 rewritten as 4.


Figure 2. Two schemes with the same likelihood as scheme (b) in Fig. 1.

This methodology has been used most extensively in analyzing the variation in the pronunciation of the word-final consonants /s/, /n/, and /r/ that characterize most varieties of Caribbean Spanish (Sankoff and Rousseau 1989).

12. Discussion

Much of this article has been phrased in terms of alternations between forms that are related in some theoretical account of phonology or syntax. However, where statistical regularities are found in linguistic performance, they are important as properties of language independent of whether they are consequences of:

(a) the physiology of articulation, in phonology;
(b) processing considerations in syntax;
(c) social or biological universals, as in the competition of tense and aspect inflections with periphrastic constructions based on verbs for standing, sitting, going, etc., or in the competition of modals with verbs for volition, ability, desire, etc.;
(d) panlinguistic typological tendencies ('parameters') which may or may not be coded in some innate form on the individual level; or
(e) some punctual actualization of the individual's grammatical facility.

There are many types of causes of statistical regularity, and which one or ones are pertinent to a given linguistic pattern remains an empirical question.

Institutions and Resources

Endangered Languages Projects (An Inventory)
L. A. Grenoble and L. J. Whaley

Predictions for language loss this century range from 30–90 percent of all living languages. Alarmed by these estimates, concerned individuals and communities have responded in a variety of ways. The type of response is determined by the status of a particular endangered language (as measured in terms of number of speakers, age of speakers, existence of support materials, and so on). Of equal relevance are factors of the local-level situation, such as size and sense of community, religious and cultural traditions, and levels and amount of contact with other languages, together with the importance of government support (or lack thereof), education policies, and so on.

1. Educational Projects

Language revitalization projects are connected to formal education in a number of ways. At one end of the spectrum are those programs which teach the endangered language, to varying degrees, as a secondary subject, much the way that a foreign language is taught. The most basic programs may teach only songs, chants, or proverbs in the language so that at least some knowledge of language and culture is maintained. At the other end are total immersion programs where children are taught exclusively in the heritage language (see *Heritage Languages*). Often these programs evolve from the lower grades, where they are first implemented, to the higher grades, developing as the children themselves pass from grade to grade.

1.1 Immersion Schools

Immersion schools are possible when a language is still widely used in a speech community. In the immersion school system, primary subjects are taught in the native language. One of the most ambitious programs, the Mohawk Kahnawake Survival School (Quebec), has been in operation since 1978. The school was established by community members and directly involves parents and elders in the classroom.

Navajo, a Native American language which is still used over a wide area in the United States, is another example of an endangered language taught on an immersion basis. In the Rock Point Community School in Arizona, reading and writing are first taught in Navajo, and then in English. In the elementary school, much of the primary curriculum is taught in Navajo, with English gradually introduced as the child progresses through the school system. By the seventh and eighth grades children receive a full year of Navajo cultural instruction in Navajo, along with a quarter term's worth of writing in Navajo.

1.2 Bilingual Education Programs

In communities where the native language is no longer the dominant language, immersion school systems are often difficult to implement. Many such communities opt for teaching the native language as a second language.

For some languages, combinations of total immersion and bilingual education models are appropriate. An example is provided by Central Yup'ik, which is taught in 22 Alaskan village schools as well as three more urban schools. Where English is the dominant language, Central Yup'ik is taught for one period a day. Where Yup'ik is still dominant, it is the primary language of instruction in kindergarten through second grade. English instruction is gradually phased in, beginning with 30 minutes of instruction per day in kindergarten and building to 90 minutes per day. By the third grade, English is the main language of instruction, but Central Yup'ik language classes continue on a daily basis.

1.3 Higher Education

There are very few institutions of higher education specifically dedicated to the promotion of endangered languages. In the US, the tribal college movement began with the foundation of the Navajo Community College in 1968. The program has developed and grown so that the American Indian

835

Higher Education Consortium (AIHEC) lists 31 members.

Another type of program is exemplified by the Gertsen Institute, which was established in the early years of the Soviet Union in St. Petersburg (then Leningrad) as a teacher-training center for indigenous minorities of the North. Subsequently, some teacher-training has been established in Moscow and in Siberian cities (such as Yakutsk). Their efforts focus on training native speakers to return to their villages to teach in local schools. A similar effort occurs at the Central Institute of Indian Languages in Mysore, India.

2. Learning Models

2.1 The Language Nest Model

The language nest model finds its origins with the Maori of New Zealand. When, in the 1960s, the Maori realized that their children were speaking English not Maori, they began a system of language 'nests' (or Te Kohanga Reo): preschool daycare centers where Maori elders worked to create a total immersion environment in Maori language and culture for the children. The success of these daycare centers led to a demand for Maori immersion elementary and then secondary schools. The model was adopted by the Hawaiian language revitalization movement (Punana Lao) in the 1980s where it has been relatively successful.

2.2 Master–Apprentice Language Learning Program

For many seriously endangered languages, there is no longer a speaker community *per se* and creating a total immersion program is impossible. The native Californian languages provide examples, as only a handful of elders still speak each language. This prompted the master–apprentice language learning program, which aims to teach individual adult students, rather than to revitalize a large speaker base. It is based on the premise that adults can learn language informally, in much the way that children do, through listening and practicing with a native speaker. This program matches teams of one master-teacher/native speaker with an individual student; they commit to working together for approximately 20 hours per week for four months, creating an intensive learning environment. When available linguistic resources are minimal (such as having only a few native speakers), the master-apprentice language learning program has proven to be one of the most effective ways of passing on some knowledge of the language.

2.3 Higher Education

A number of programs for the study of endangered languages exist at the level of higher education. Beyond language courses affiliated with linguistics departments, some institutions specialize in the education and promotion of specific endangered languages and cultures. For example, *Studienzentrum für Keltische Sprachen und Kulturen* (the Study Center for Celtic Languages and Cultures at http://www.sksk.de/) offers courses in modern Celtic (Irish, Welsh, Breton, and Scottish Gaelish). Celtic studies are also widely taught at the universities in their own territories (e.g., Aberdeen, Belfast, Dublin, and Wales, to name just a few).

2.4 Cultural Programs

Some groups have taken a different approach and consciously rejected formal education programs. In a few cases this decision comes from a lack of resources (be it financial, linguistic, or human), but some groups argue against formal education on the grounds that it will fundamentally change the language and culture. The Tohono O'odham (in Northern Mexico and Southern Arizona in the US), for example, are committed to language use in traditional ways, such as in song, dance, and oral literature.

3. Resource Development

One of the greatest challenges facing revitalization programs is the development of pedagogical and other materials for teaching or in some way using the endangered language. Educational programs are often implemented to revitalize and preserve languages, and these require a broad range of pedagogical materials, ranging from dictionaries and reference grammars to textbooks written in the endangered language. Recent technological advances support the development of relatively inexpensive language materials for groups which have computers and Internet access. Some tools for resource development (such as fonts and software, as well as some links to support organizations) can be found at the Endangered Languages Homepage of the Linguistics Society of America. A large number of online language courses are offered; the Gaelic languages can all be studied online through a variety of programs, a possibility for a number of Native American languages as well.

The creation of resources often first requires the development of a written language. Determining the dialect upon which to base the standardized language is far from trivial. Ideally, the standardized variety will be one that is readily comprehensible to all speakers of all dialects, but when dialect variation is extensive, this may be impossible. Language planners often opt to make standard the dialect which has the greatest speaker base, or is centrally located, or has some particular historical or social prominence. The role of the linguist here is crucial, as the linguist is often in a position to answer questions of linguistic accuracy, typological consistency, or diachronic validity.

The development of orthographies (see *Orthography*) can be equally problematic. A group may turn to the alphabet used by a national language, but often this alphabet may either lack sufficient symbols to represent the endangered language's phonemes, or may have too many (or redundant) symbols. A given orthographic system may also create access to the written form of the majority language (thereby facilitating language shift).

4. Organizations

Many organizations have been developed to address issues of language documentation, revitalization, and retention. Some operate on a local level only, such as the Shuar Federation in the lowlands of Ecuador, which has been working to preserve use of the Shuar language since the 1970s. Some are more broadly based, such as the Native American Language Center, which is concerned with all of the indigenous languages of California. A number of international organizations work to support research or community language preservation efforts, or to collect and disseminate information on the status of endangered languages. In addition to these, there are a great many language-specific and regional foundations that are not listed here.

4.1 Foundation for Endangered Languages

The Foundation for Endangered Languages has specific educational and scholarly goals, seeking to raise awareness of the plight of endangered languages; to support the use of languages, through community-based programs and the monitoring of policies and political structures; to support research and education programs; and to fund the dissemination of information.

4.2 International Clearing House of Endangered Languages (ICHEL) and the UNESCO Red Book on Endangered Languages

This international organization acts as a clearing house for information on the status of endangered languages and descriptive information of many of the world's languages. The ICHEL works in conjunction with the UNESCO Red Book project; the primary goals of these projects are to conduct field work, and to create electronic corpora of published and unpublished materials (e.g., texts, word lists, and phonetic data).

4.3 Gesellschaft für bedrohte Sprachen (Society for Endangered Languages)

The society was founded in 1977 by a group of German linguists, together with linguists from the 'Endangered languages' research group of the German Society for Linguistics in Cologne. This is a non-profit organization which aims to promote the use, preservation, and documentation of endangered languages by supporting research, field work, and community efforts; by taking a proactive stance in promoting national and international cooperation between researchers; and by informing scientific and public communities about the issues of language endangerment.

4.4 Endangered Language Fund

The Endangered Language Fund, based at Yale University, provides research grants for the study of endangered languages. The fund also supports community-based efforts to preserve minority languages and supports the dissemination of information to the native communities and the scholarly world.

4.5 Terralingua

Terralingua is an internationally-based non-profit organization which is concerned with the status of minority languages in terms of not only linguistic, but also cultural and biological diversity. It is an advocacy group which supports research and the continued development of linguistic diversity, as well as studies of the interrelations between linguistic, cultural, and biological diversity.

4.6 The Native American Language Issues Institute (NALI)

NALI is a non-profit organization which was established in 1980. Its primary goals are to strengthen Native American languages and cultures while functioning as a language institute, training future educators and offering university credit for this training. It sponsors an annual institute, which aims to facilitate interaction between language practitioners and language professionals.

4.7 Aboriginal Languages of Australia

A large number of organizations in Australia are devoted to the documentation and development of the aboriginal languages. At the national level are such organizations as the Aboriginal and Torres Strait Islander Corporation of Languages (FATSIL), the Australian Indigenous Languages Framework (AILF), and Language Australia (formerly NLLIA), which is based at the Australian National University in Canberra. In addition, there are many smaller organizations, which operate on a more local level.

4.8 The Mercator Project

Mercator was established by the European Commission in 1987 to meet the address issues of minority and regional languages in the European context. Mercator is a network of three research centers, which each have related missions: the Mercator Education at the Fryske Akademy in The Netherlands studies education at all levels; Mercator Legislation at the CEIMEN foundation, Barcelona, focuses on language legislation and language in

837

public administration; and Mercator Media at the University of Wales, Aberystwyth, works with the press and the media, including the new media.

4.9 European Bureau for Lesser-used Languages

Based in Brussels, this Bureau works to achieve the best European policies for lesser-used languages. Its goals to protect and promote the use of minority languages are achieved through linking linguistic communities with local and regional authorities in the member states of the European Union to promote the implementation of fair policies for these communities, and to increase awareness of relevant linguistic issues.

Internet Resources for Sociolinguistics

A. Deumert

The rise of the Internet in the early 1990s opened up new ways of exchanging scientific information, and today the Internet provides sociolinguistic researchers with a wealth of language-related material. There are three main types of resources available: (a) mailing lists, which constitute informal channels for scientific communication; (b) websites of individuals, research institutes, academic departments, and professional associations, offering access to data bases as well as information about specific languages or areas of linguistic research; and (c) electronic journals.

1. Mailing Lists

Mailing lists enable e-mail users to broadcast (via a central list-server) e-mails to groups of other e-mail users. These lists serve as forums for questions and answers. They distribute relevant information and allow for on-line discussions of specific topics. The Linguist List (founded in 1990, http://www.linguistlist.org/) is the chief mailing list for linguists, covering all areas of linguistic research. A group of moderators ensures the academic standard of list postings. More specialized mailing lists are the CreoList (http://www.su.se/Creole/) which is dedicated to the discussion of pidgin/creole studies, and the multi-disciplinary Language-Culture List (http://www.language-culture.org/). Other mailing lists, which are of interest to sociolinguists are, for example, the Discourse Studies List (DISCOURS), the endangered languages list (ENDANGERED-LANGUAGES-L), the ethics list (ETHICS), the heritage language education list (HERITAGE), and the linguistic anthropology discussion group (LIN-GANTH). A register of mailing lists can be found on the Linguist List website, which also offers on-line access to the list's archives, information about the profession, conference announcements, dissertation abstracts, and bibliographies. Valuable links to linguistic Internet resources can be found at the Virtual Library of Linguistics (http://www.cog.brown.edu/pointers/linguistics.html).

2. Websites

2.1 Diversity on the Internet: Languages and Dialects of the World

Web-based language documentation is particularly useful for smaller, less-studied languages where the target audiences are small and conventional means of publication would have been costly. The American Indian Resources page, for example, provides access to on-line dictionaries and linguistic descriptions of American Indian languages, as well as cultural and educational material (http://www.lang.osaka-u.ac.jp/~krkvls/lang.html).

An emphasis on linguistic diversity, minority language rights, and language documentation is also characteristic of the following sites.

(a) ERIC Clearinghouse on Language and Linguistics (ERIC-CLL, http://www.cal.org/ericcll/): services and materials with a focus on language and education, including a large bibliographic database. It is operated by the Center for Applied Linguistics, Washington, USA.

(b) International Clearing House for Endangered Languages (Department of Asian and Pacific Linguistics, University of Tokyo, Japan, http://www.tooyoo.l.u-tokyo.ac.jp): databases, resources, and bibliographies on minority and endangered languages, on-line access to the UNESCO Red Book of Endangered Languages.

(c) Language Varieties Network (http://une.edu.au/langnet, University of New England, Australia): sociolinguistic descriptions of

non-standard varieties such as, for example, Geordie (Newcastle upon Tyne), Kamtok (Cameroon Pidgin English), Singlish (Singapore Colloquial English), and Aboriginal English (Australia).

(d) Rosetta Project (http://www.rosettaproject. org): publicly accessible, full-text archives of 1000 + languages. Languages are documented as follows: description (typology, history, and current status), genesis translation, glossed vernacular texts, orthographical system, Swadesh word list, phonemic inventory, and audio files. The information is collected through an open contribution model.

(e) SIL International (The Summer Institute of Linguistics, http://www.sil.org): from this page one can link to the Ethnologue, an electronic database of the world's languages. It includes information on the status of languages (official language, medium of instruction, etc.) speaker numbers, location, dialects, speaker bilingualism, linguistic affiliation, literacy, Bible translations, and alternate language names. The Ethnologue provides information about more than 6700 languages in over 200 countries.

(f) Gay language research (http://www.msu.edu/ ˜greenm14/outil/gaybib.html). This site contains a regularly updated bibliography of sources relevant to gay language research.

Urban and regional dialectologists in North America and Europe have also begun to make use of the Internet for publication of their research, including maps and (written or acoustic) samples of the language data. Detailed background information and data files are available for the North American Linguistic Atlases (http://us.english.uga.edu). Some of the maps of the Phonological Atlas of North America (see *The Atlas of North American English*), which was produced under the leadership of William Labov, are also available on-line (http://www.ling. upenn.edu/phono_atlas/home.html). In Europe, the research institute *Deutscher Sprachatlas* (http:// www.uni-marburg.de/dsa/) allows on-line access to its digitalized German dialect maps.

2.2 Corpus Linguistics and the Internet

Electronic linguistic corpora are available via the Internet for research purposes. The language data is either presented in its raw form or annotated (i.e., tagged for grammar or semantics). Michael Barlow's Corpus Linguistics page at Rice University (http://www.ruf.rice.edu/˜barlow/corpus.html) provides links to corpora in several languages (including, for example, Chinese, Gaelic, Malay, Russian, etc.), as well as links to sites providing parsing software. Linguistic databases and parsing software can also be found at the Linguistic Data Consortium (http:// ldc.upenn.edu). The Child Language Data Exchange

System (CHILDES, http://childes.psy.cmu.edu/) gives access to its database of transcripts of first and second language learners, as well as to software for data analysis. There also exist corpora of lesser used languages such as the databases of Maori newspapers (1842–1933, http://www.nzdl.org/cgi-bin/ niupepalibrary?a = p&p = about) and Hawaiian newspapers (1834–1927, http://128.171.57.100/hnp/index. shtml). The Archive of the Indigenous Languages of Latin America (AILLA, University of Texas, USA, http://www.ailla.org) holds an electronic data base of audio files and texts. The archive's focus is on naturally occurring discourse. An extensive corpus of literary texts can be found at the Project Gutenberg (http://www.gutenberg.net).

3. Electronic Journals

The advent of the Internet has changed the face of academic publishing. Many traditional journals have begun to provide electronic versions of their texts, which can be accessed with personal identification via university libraries. There also exist a number of electronic journals, which do not have a printed version, and many of these are available free of charge. An example of such an electronic journal is the *Journal for Computer Mediated Communication* (http://www.ascusc.org.jcmc/) which publishes sociolinguistically oriented articles on Internet language use. Other electronic publications of interest for sociolinguists are:

(a) *The Web Journal of Modern Language Linguistics* (http://wjmll.ncl.ac.uk).

(b) *Historical Sociolinguistics and Sociohistorical Linguistics* (http://www.leidenuniv.nl/English/ staff/tieken/Internet%20journal/).

(c) *Linguistik-Online* (http://linguistik-online.com).

(d) *Electronic Journal of Communication* (http:// www.cios.org/www/ejcmain.htm).

(f) *Marges Linguistiques* (http://www.marges-linguistiques.com).

4. Envoi

The network of linguistic Internet resources is continuously growing and changing. Some of the resources listed here might thus change their locations (i.e., their URLs, uniform resource locators) in the foreseeable future and new material will become available. Internet search engines, such as Google, Lycos, or Yahoo, can help to locate up-to-date mailing lists, web pages, and journals. The conventions for citing Internet sources can be found at http://www.linguistlist.org/citing.html.

Professional Associations

R. Mesthrie

This section lists some of the main sociolinguistic organizations involved in the presentation and evaluation of research via regular conferences and publications. The list is by no means exhaustive. It is better seen as a starting point.

1. American Association for Applied Linguistics (AAAL)

Many papers in the area of sociolinguistics and education are presented at AAAL. Its annual conference is held in the northern hemisphere in spring. AAAL is the largest affiliate of the *Association Internationale de Linguistique Appliquee* (AILA). Its website is: www.aaal.org

2. American Dialect Society

This society was started in 1889. Its original publication was *Dialect Notes*, now a monograph series retitled *Publications of the American Dialect Society*. It publishes the journal *American Speech* (volume 76 in 2001). Its website is: www.americandialect.org

3. Association Internationale de Linguistique Appliquee (AILA)

This is an international federation of about 35 national associations of applied linguistics founded in 1964. It hosts the World Congress of Applied Linguistics, which is organized by an affiliated member every three years. It publishes a newsletter, *AILA News*, and the journal *AILA Review* (volume 15 in 2001). Its website is: www.aila.ac

4. British Association of Applied Linguistics (BAAL)

Started in 1967, the association organizes an annual conference, at which many sociolinguistic papers are presented. It publishes a newsletter and conference proceedings. Together with AILA (of which it is an affiliate) and AAAL, the association produces the journal *Applied Linguistics* (published by Oxford University Press; volume 22 in 2001). Its website is: www.baal.org.uk

5. International Association for World Englishes (IAWE)

This society, which held its first conference in 1992, is concerned with the sociolinguistic and applied sociolinguistic aspects of the spread of English. It hosts annual conferences in different parts of the world and is associated with the journal *World Englishes* (published by Blackwell; volume 20 in 2001). Its website is: http://we.pdx.edu

6. International Pragmatics Association (IPrA)

This association covers some aspects of interest to sociolinguistics, especially intercultural communication. Based in Belgium, the association organises the International Pragmatics Conference and publishes the journal *Pragmatics*. Its website is: http://ipra-www.uia.ac.be/ipra/

7. New Ways of Analyzing Variation (in English and other languages) (NWAV(E))

This society, founded in 1971, is concerned specifically with sociolinguistic variation as studied within the quantitative paradigm. Its main focus is on North American research. The society meets annually at a North American university. It produces the journal *Language Variation and Change* (published by Cambridge University Press; volume 13 in 2001).

8. Society for Pidgin and Creole Languages (SPCL)

The society, which was started in 1989, hosts an annual conference, which coincides with the winter meetings of the Linguistic Society of America. It is associated with the *Journal of Pidgin and Creole Languages* (published by Benjamins; volume 16 in 2001).

9. Sociolinguistic Symposium (SS)

This is a loosely structured association started by British sociolinguists in 1976. It hosts a biennial conference usually held in the United Kingdom, though for the first time in 2002 the conference is being in continental Europe. All aspects of sociolinguistics are covered, with an emphasis on linguistic variation in the British context. Its website is: www.uwe.ac.uk/facults/les/research/sociling2000.html

10. International Association for Forensic Phonetics (IAFP)

This association was established in 1991 to regulate and assist the practice of speech analysis for legal purposes. It aims to ensure that practitioners are suitably qualified, to fix ethical and practical guidelines for analysis, and to promote research. It is associated with the journal *Forensic Linguistics*. Its website is: www.iafp.net

11. International Association for Language and Social Psychology

Although conferences of this group go back to 1979, the association was formally instituted in 1997. It has close links with the *Journal of Language and Social Psychology* (published by Sage; volume 20 in 2001).

12. International Association of Intercultural Communication Studies (IAICS)

The association was founded in 1991, after a series of Asian–USA conferences. Conferences are held biennially in Asian and US centers. The association's headquarters are at the Institute for Cross-Cultural Research at Trinity University in San Antonio, Texas. It runs the journal *Intercultural Communication Studies*. Its website is: www.louisville.edu/~rnstcl01/IAICS-ICS.htm

13. International Gender and Language Association (IGALA)

This association developed out of the graduate-student run Berkeley Women and Language Group into an international association in 1999. It is an interdisciplinary organization that promotes and supports research on language, gender, and sexuality. The organization hosts a biennial conference: IGALA 1 was held at Stanford University in 2000. GALA-L is the official electronic list of the association.

14. International Society for Dialectology and Geolinguistics (SIDG)

The society is concerned with the study of dialectology and geolinguistics in the international context as well as the study of minority languages and dialects. Its executive members are drawn mainly from continental Europe. The society publishes the journal *Dialectologia et Geolinguistica* (published by Edizioni dell'Orso; volume 9 in 2001) and the SIDG bulletin. It organizes an international congress of dialectology and geolinguistics at least once every three years. Its website is: www.uni-bamberg.de/~ba4es1/sidg.html

15. Societies for Endangered Languages

Many countries do not have specifically sociolinguistic associations: rather their national linguistics associations carry a heavy emphasis on sociolinguistics. This is true, for example, of the *Society for Caribbean Linguistics*; the *Linguistics Society of Southern Africa* (http://www.puk.ac.za/lssa/index.html) and the *Linguistics Society of India*. (See: *Endangered Language Projects: An Inventory*).

Likewise research centers in sociolinguistics are too numerous and scattered to be covered adequately here. However, mention must be made of a few centers and institutes that have had a major influence in sociolinguistics and applied sociolinguistics.

16. Le Centre Internationale de Recherche sur le Bilingualisme

Established in the 1960s at the University of Laval, Quebec, and re-established with a change of name (*Le Centre Internationale de Recherche en Aménagement Linguistique*), this center is a pioneer in the field of language policy and educational linguistics. It maintains a web database on language policy in countries throughout the world. Its website is: http://www.ciral.ulaval.ca

17. The Center for Applied Linguistics

This center was established in Washington, DC, in 1959 and has been closely associated with the rise of sociolinguistics and applied linguistics in the United States. It deals with a variety of issues including language policy, English as a second language, foreign language education and testing, immigrant education, and refugee affairs. Its website is: http://www.cal.org

18. The Center for Research and Documentation on World Language Problems

Based in New York, this center produces the journal *Language Problems and Language Planning* and the newsletter *Informilo por interlingvistoj*. It organizes conferences on language and communication in conjunction with the United Nations Translation Service.

19. Summer Institute of Linguistics (SIL)

This institute began in 1934 with a summer school to teach young people indigenous languages. Since then it has grown into a major organization that has come to be known for its work in Bible translation. Notwithstanding this proselytizing function, the organization has been involved in inculcating literacy, cultural awareness, teacher training, developing field methods, and theories of linguistic description. One of the most widely used books published by SIL is the *Ethnologue*, edited by Barbara F. Grimes, which is a comprehensive listing of the languages of the world country by country, with details about demographics, dialects, extent of bilingualism, and the state of Bible translation. Its website is: www.sil.org

A useful reference work on sociolinguistic and language planning organizations throughout the world is Domínguez and López (1995).

Sociolinguistics Journals: A Critical Survey
N. Coupland

Reviewing the journals of any discipline is tricky territory, especially for a partisan journal editor. Listing journals as lying 'inside' or 'outside' Sociolinguistics will highlight boundary disputes, although to air these is probably the most useful ambition for this entry. Recklessly therefore, over-reliant on 12 as a conventionally round number, here is a subjective list of 'core' international sociolinguistic journals, alphabetically by title, with their 2001 volume or issue numbers and publishers:

(a) *Discourse and Society* (12), Sage
(b) *International Journal of Bilingualism* (4), Kingston Press
(c) *International Journal of the Sociology of Language* (issue 148), Mouton de Gruyter
(d) *Journal of Language and Social Psychology* (20), Sage
(e) *Journal of Multilingual and Multicultural Development* (21), Multilingual Matters
(f) *Journal of Pidgin and Creole Languages* (16), Benjamins
(g) *Journal of Sociolinguistics* (5), Blackwell Publishers
(h) *Language in Society* (30), Cambridge University Press
(i) *Language Variation and Change* (13), Cambridge University Press
(j) *Multilingua* (20), Mouton de Gruyter
(k) *Pragmatics* (11), International Pragmatics Association
(l) *Research on Language and Social Interaction* (34), Lawrence Erlbaum Associates

Of these, *Journal of Sociolinguistics* and *Language in Society* are most comprehensive in their coverage of the field, with others in the list tending towards specialist sub-fields. A secondary list comprises an array of important journals, which are listed separately for the reasons specified below:

(a) smaller scale, avowedly sociolinguistic journals such as *Current Issues in Language and Society, Current Issues in Language Planning* and *Sociolinguistica*;
(b) non-primarily-English language journals, such as the *Japanese Journal of Language and Society* and *Estudios de Sociolingüística* which publishes in English and Spanish, although Sociolinguistics needs to be more multilingual in its publishing;
(c) exclusively English-focused journals, such as *English World-Wide, World Englishes, American Speech*, and the more 'popular' *English Today*;
(d) general journals in Linguistics, such as *Journal of Linguistics, Language, Language Sciences, Lingua, Linguistics* and *Word*;
(e) journals in the field of Communication, such as *Human Communication Research, Journal of Communication, Language and Communication, Semiotica* and *Social Semiotics*;
(f) journals mainly focusing on language education or in some other sense Applied Linguistics, such as *Applied Linguistics, Forensic Linguistics, International Journal of Applied Linguistics, International Review of Applied Linguistics, Language Awareness, TESOL Quarterly*, and *Written Language and Literacy*;
(g) sociological, social psychological and anthropological journals, like *Anthropological Linguistics* (which would be 'core' Sociolinguistics for many), and *Annual Review of Anthropology, Journal of Social Issues, European Journal of Social Psychology* and *Sociological Inquiry*;
(h) psycholinguistic journals such as *Journal of Child Language* and *Language Learning*;

(i) nationally focused journals, such as New Zealand's *Te Reo* and *Southern African Linguistics and Applied Language Studies*;

(j) university working papers, including the University of Liverpool's very sociolinguistic *Language and Discourse*;

(k) journals in the field of discourse analysis, such as *Discourse Processes, Discourse Studies, Journal of Pragmatics* and *Text*;

(l) new journals like *Language Policy* whose first issue is due 2002;

(m) the new Internet journal *Marges Linguistiques*.

These lists point to the vast multidisciplinarity and, in many instances, genuine interdisciplinarity of Sociolinguistics. Many of the journals in the secondary list sustain much of the critical qualitative research that is becoming central to Sociolinguistics. Sociolinguistics might reasonably be characterized as 'the study of language in society and of society through linguistics.' But in that formulation 'society' is obviously shorthand for a complex, interlocking set of socio-structural, cultural, contextual, relational, and human developmental processes. Some specialist journals pick up on language as it relates to specific domains of such processes—like forensic science, aging, adolescence, health or teaching, and learning. Scholarship at these and similar interfaces is focally, not at all peripherally, sociolinguistic.

What justification is there, then, for identifying a 'core' constituency of sociolinguistic journals at all? Although not watertight, the main one is historical/institutional, in that these journals have been and are now particularly influential in giving Sociolinguistics its shape and status. More than any other journal, *Language in Society* has consolidated Sociolinguistics as a centered, coherent discipline. While it has remained open to work of many denominations, it has majored on anthropological and cultural research. It has carried analyses of minority cultural styles, texts, and events, more qualitative and interactionally focused research than quantitative surveys, and integrative theoretical work. Macro-sociological research on language has been the main domain of the *International Journal of the Sociology of Language*. It is an invaluable, substantial archive of empirical studies, often surveys, themed around specific sociolinguistic communities or languages. This is where Sociolinguistics' prioritization of global linguistic diversity is most apparent. More recently, quantitative, variationist research has *Language Variation and Change* as its home base, and variationism remains the most rigorous empirical tradition in Sociolinguistics, particularly in the United States. These three journals have gained their reputations under the guidance of some of Sociolinguistics' most inspira-tional figures—William Labov, Dell Hymes, and Joshua Fishman.

Other journals in the 'core' list have similarly promoted distinctive sociolinguistic traditions. For example, *Journal of Language and Social Psychology* has contributed much-needed cognitive emphases, strong empirical (often experimental) procedures, and cumulative theory-building. *Discourse and Society* is explicitly committed to ideological, socio-political, critical, and qualitative approaches to language. *Research on Language and Social Interaction* has supported Conversation Analysis research, extending the general traditions of Ethnmethodology and Symbolic Interactionism. *Journal of Multilingual and Multicultural Development* and *Multilingua*, self-evidently in their titles, promote multilingualism studies as well as more general Sociolinguistics. *Pragmatics* makes the 'core' list because, possibly more extensively than other journals in the wide territory of text, discourse, and social interaction, it works to integrate cognitive, social, and cultural approaches to language.

The glib but true generalization behind the list is that Sociolinguistics is admirably served by high-quality and diverse international journals. There is a clear tendency across the set towards specialization or, in the commercialist discourse, niche marketing. This is both a strength and a weakness. Any discipline will thrive on robust competition between its schools and traditions. Individual research initiatives need, at least to some extent, to fit into an architecture of pre-existing assumptions and established knowledge. Specialist journals constitute the architecture for research in their own traditions. The downside, of course, is a propensity towards insularity and dogma, and Sociolinguistics is at risk from these tendencies. Let me briefly itemize some arenas where more boundary crossing and debate is needed.

The hoary contrast between quantitative, empiricist, objectivist, survey-based research and qualitative, interpretive, insider-perspective research is all too much alive in Sociolinguistics. One unfortunate consequence is that sociolinguists interested in quantifying dialect variation and change rarely entertain discursive, richly contextualized data. Correspondingly, interactionists rarely attend to phonological nuance or to trend data across large samples. Pre-defined socio-structural categories are the *modus vivendi* for urban variationists but are targeted as naïve essentializing by constructivist discourse analysts. There are important arguments on both sides (if indeed there are only two sides here), but there is little dialog encompassing them. Similarly, cognition provides the starting point for social psychological accounts of sociolinguistic motivations, attitudes, and stereotyping. Yet Discursive Psychology, in the manner of Conversation

Analysis, is resolutely anti-cognitivist. Anthropological work, which is currently developing rich and challenging theories of performance and cultural reproduction, has little exposure in other sociolinguistic areas. A wider problem is that sociolinguistic theory is generally built in small pockets, to sub-disciplinary tolerances (see Figueroa 1994). The general, urgent point is that we need more inclusive theoretical debate within Sociolinguistics, across its own sub-traditions, and then more confident engagement by Sociolinguistics as a whole with social theory (see Coupland et al. 2001).

A forum is therefore needed where the multiple sub-traditions of Sociolinguistics can be seen, re-assessed, and perhaps realigned—where new 'cores' can be bred. This was my own and Allan Bell's objective in founding the *Journal of Sociolinguistics*. Any journal's primary ambition has to be to publish work of the best quality in its field, but the *Journal of Sociolinguistics* also endeavors to sustain a metatheoretical and reflexive debate on the nature, boundaries, and future of Sociolinguistics. One element of this is a series of Dialogue contributions on 'Sociolinguistics and the community,' asking, not least, why such a vibrant, innovative and radical discipline has had so little impact to date on the communities it researches (see *Fieldwork Ethics and Community Responsibility*). Probably the greatest challenge for *all* Sociolinguistics journals, and for the discipline as a whole, is to critically monitor and then to seek to reduce the boundaries between academic Sociolinguistics and the divided worlds of language users.

Profiles of Sociolinguists

Ammon, Ulrich (1943–)

A. Deumert

Ulrich Ammon is a central figure in German and European sociolinguistics. His work includes research on dialect and sociolinguistic disadvantage in the classroom, language planning, standardization, international languages, and communication (see *International Languages*), and the variety spectrum of the German language.

Born in 1943 in Backnang, Swabia, Germany, Ammon studied German, English, and cultural anthropology at the universities of Tübingen, Göttingen, and Frankfurt and at Wesleyan University (Connecticut, USA). He completed his studies in 1971 with the state examination for teachers, and received his PhD at Tübingen in 1972. In 1971 he was appointed head of the research project 'School difficulties of dialect speakers' at the University of Tübingen, where he also worked as a lecturer until 1974. He then took up an appointment at the University of Duisburg. Since 1980 he has been professor for German linguistics at Duisburg.

Ammon's early sociolinguistic work (cf. Ammon 1973) was broadly based on Bernstein's theories of social inequality and language barriers in education (see *Bernstein, Basil*). Ammon's research showed a strong interaction of social class membership, dialect usage, and knowledge of the German standard variety in southwest Germany. The higher speakers were situated on the social scale, the better was their knowledge of the German standard language; speakers who occupied lower social positions, on the other hand, spoke the local dialect and had only limited knowledge of the (structurally dissimilar) standard variety. In the educational system, which relies on the standard language as a medium of instruction, dialect-speaking children were found to underperform when compared to their peers.

Ammon also contributed to the study of language norms, language planning, and language standardization, with a focus on the description of the national varieties of German (which as a pluricentric language has different centers of standardization; i.e., Austria, Germany, and Switzerland, cf. Ammon 1995), and the status changes of European standard languages (in particular German) vis-à-vis English. In his monograph *Die internationale Stellung der deutschen Sprache* ('The international status of the German language,' 1991a) Ammon traces the history of the demise of German as an international language of scientific communication in detail. Some years later he approached the subject once more in the book *Ist Deutsch noch internationale Wissenschaftssprache?* ('Is German still an international language of science

and research?' 1998), where he discusses the impact of this development on the future educational policies in tertiary institutions.

Together with Norbert Dittmar (see *Dittmar, Norbert*) and Klaus J. Mattheier, Ammon edited the comprehensive bilingual (English-German) handbook *Sociolinguistics/Soziolinguistik* (1987/1988). He is one of the editors of the Yearbook of European Sociolinguistics, *Sociolinguistica*, which publishes papers in German, English, and French (founded 1987; co-editors of *Sociolinguistica* are Klaus J. Mattheier and Peter H. Nelde). He is (1998–2002) vice-president of the research committee on sociolinguistics, which has been established by the International Sociological Association (ISA).

Bakhtin, Mikhail M. (1895–1975)

J. M. Weir

Bakhtin was born on November 16, 1895 in Orel, a provincial town south of Moscow. Although his family belonged to the nobility, Bakhtin's father owned no property and worked as a state employee in various banks. Bakhtin completed the gymnasium in Odessa, and entered the philological faculty of the city's university. In 1914 he transferred to St. Petersburg University, where he stayed until 1918. Three years later Bakhtin married Elena Okolovich while living in Vitebsk, a cultural center outside of the capital during the Civil War; husband and wife remained together until her death in 1971. From the mid-1920s Bakhtin lived in Leningrad until his arrest in 1929 on charges related to his intellectual and religious affiliations. He was subsequently exiled to a small city in Kazakhstan and, with the exception of a couple of years, he remained in the provinces until 1969 when he moved to Moscow from Saransk, where he had been teaching in the pedagogical institute. He died in Moscow on March 7, 1975.

Because the majority of his written work was not published until after 1970, and much of the earliest of that not until the latter half of the 1980s, Bakhtin's intellectual biography and reception have only recently begun to take clear shape, culminating in an international centennial conference in 1995 devoted to his life and work. Four more or less distinct periods describe the range and development of Bakhtin's thought (Clark and Holquist 1984, Morson and Emerson 1990).

His earliest and most philosophical period includes the substantial essays 'Toward a philosophy of the act,' 'Author and hero in esthetic activity,' 'The problem of content, material, and form in verbal art,' and the brief 'Art and answerability' (Bakhtin's first publication), all of which were written before 1925. These essays reflect Bakhtin's interest in Marburg neo-Kantianism and describe the ethical act and its subsequent aestheticization in terms influenced by the phenomenology of vision.

Bakhtin's second period was from 1925 to 1929 and ended with *Problems of Dostoevsky's Creative Art* (1929), a monograph proclaiming Dostoevsky inventor of a new kind of novel, the 'polyphonic' novel, in which the author grants his heroes consciousnesses liberated from authorial control. Bakhtin's well-known concept of dialogue is located in this book, but the give and take of semantic authority suggested by the term probably also emerges from the nature of Bakhtin's close relationship with other scholars (the Bakhtin circle), most notably Valentin Voloshinov (see *Voloshinov,*

Valentin Nikolavic) and Pavel Medvedev. Scholars have disputed whether the books published by Voloshinov and Medvedev in 1927–29 were not in fact the work of Bakhtin himself, though there is scant evidence to support such a contention.

The writings of the third period stretch through the 1930s and 1940s and constitute the body of texts most familiar to Western readers. Bakhtin's essays translated in *The Dialogic Imagination* (Bakhtin 1981), including 'Epic and novel,' 'Discourse in the novel,' 'Toward a prehistory of the Bildungsroman,' and 'Forms of time and chronotope,' all belong to this period. Bakhtin defended his doctoral dissertation in 1946, receiving the penultimate 'Candidate' degree after much heated debate, and the dissertation was later published as *Rabelais and His World* (Bakhtin 1968). His essay on methodology in the humanities and his reworking of the Dostoevsky monograph belong, by contrast, to the fourth and final period, when Bakhtin was in Moscow working with students devoted to his ideas, and when he finally achieved the professional recognition that had eluded him (or that he himself eluded) for the previous 35 years.

In general, Bakhtin rejects the Saussurean notion that the locus of meaning ultimately belongs to the abstract system ('langue') of language rather than to the agent's highly contextualized, historicized use of it as 'utterance.' Meaning is, thus, to be found in neither 'langue' nor 'parole,' which Bakhtin viewed as merely the cited instance of an underlying rule. He formulates his objection more provocatively: 'A code is only a technical means of transmitting information; it does not have cognitive, creative significance. A code is deliberately established, killed context' (Bakhtin 1986: 147). This is the first way that Bakhtin uses dialogue: every (spoken) utterance is by its very nature dialogic, and meaning is established through the utterance's intrinsic orientation toward other concrete utterances. Unlike the (written) sentence, an utterance can never mean the same thing twice; it is always a rejoinder to what has previously been said and an anticipation of the response it will in turn demand.

Bamgbose, Ayo (1932–)

R. Mesthrie

Ayo Bamgbose is one of Africa's foremost sociolinguists. He was born in Nigeria and did his schooling there. He attended St. Andrews College in Oyo and later proceeded to the University College, Ibadan. Links between this university and the University of London enabled him to study for an honours degree in English in London. Between 1960 and 1963 he studied at the University of Edinburgh, where he completed his PhD on Yoruba grammar. He studied under, *inter alia*, Michael Halliday (see *Halliday, Michael Alexander Kirkwood*) and was part of the 'Edinburgh group' made up of students like Braj Kachru (see *Kachru, Braj B.*), Ruqaiya Hasan, Rodney Huddlestone, John Mountford, together with John Sinclair (on the faculty) and Robert W. Dixon (research fellow).

He taught in primary and secondary schools in Nigeria before assuming a lectureship at the University of Ibadan, rising to professor in 1968. Bamgbose's research interests are wide, spanning theoretical linguistics (the syntax and phonology of Yoruba); sociolinguistics (language, literature, and oral culture); and, necessarily in his context, attention to applied linguistics (language planning; language

medium in schools; orthography; curriculum development). Amongst his many publications in these three fields, one can cite *A Grammar of Yoruba* (1966), which was the first grammar of the language based on modern linguistic theory; *Language and the Nation* (1991), which drew attention to language in the broad context of socioeconomic and political problems with particular reference to sub-Saharan Africa; and *The Novels of D.O. Fagunwa* (1974), which was the first full-length critical work on any author writing in Yoruba.

Inevitably Bamgbose has been frequently invited to lecture abroad, doing several stints as a visiting professor in the US and Germany in particular. He has nevertheless continued to develop scholarship in West Africa, by serving on a number of editorial boards of local and international journals; by holding office in important societies (e.g., West African Linguistics Society) and journals (e.g., *Journal of African Languages*); and by doing research on behalf of UNESCO. He was invited as an expert to 14 UNESCO conferences between 1971 and 1998. He was the editor-in-chief of the journal *Education and Development* between 1985 and 1987; president of the West African Linguistic Society between 1976 and 1982; the first president of the Nigerian Academy of Letters (1998); and president of the International Association of World Englishes (1999).

A full appreciation of Bamgbose's personal and scholarly qualities can be seen in this tribute from his former fellow student, Braj Kachru, in the preface to Bamgbose, Banjo and Thomas (eds.) (1995: v):

> ... over the past three decades, Ayo Bamgbose has become a guru of African linguistics, an African presence in international conferences of our profession,

and a voice of wisdom and experience. He has indeed made ground-breaking contributions to diverse academic areas in his chosen discipline. These contributions have rightly been recognized by the profession nationally and internationally. While engaged in all these activities, Bamgbose has not shirked from doing equally demanding things for his continent and for all of us working in relating linguistics to the real world. In his own way, he has brought social realism and social concern to the profession to which he has devoted over four decades as a teacher, researcher, and academic administrator.

In 1990 Bamgbose was awarded the Nigerian National Order of Merit, the country's highest award for intellectual and academic achievement. He gave his valedictory lecture 'A view from the Ivory Tower' at the University of Ibadan in 1991, but remains active as a researcher, visiting lecturer and editor.

Baugh, John (1949–)
R. Mesthrie

John Baugh was born in New York and grew up in Los Angeles. He graduated with a BA from Temple University, where he majored in Speech and Rhetoric. He received his MA and PhD from the University of Pennsylvania with a dissertation on 'Linguistic Style Shifting in Black English,' supervised by William Labov (see *Labov, William*). At Penn he also came under the influence of John Fought, Dell Hymes (see *Hymes, Dell Hathaway*) and Erving Goffman (see *Goffman, Erving*). Since then, Baugh has become one of the leading scholars of African American Vernacular English (AAVE), paying attention to matters of linguistic structure, ethnography,

applied linguistics, and issues of power, equity and access in US society.

One of his early contributions was 'A re-examination of the Black English copula' (1980) in which he revisited Labov's famous analysis of 1969. Baugh used an extension of Labov's original database (utilizing the data from the Harlem adolescent groups in full) and an update of the Cedergren and Sankoff (1974) program in his re-examination. With the resulting extra tokens, he was able to separate two environments that Labov had conflated out of procedural necessity, the original number of tokens for locative and adjective environments being too

847

small for reliable statistical analysis. Baugh showed that these two environments had a differential effect: for locatives, contraction was favored over deletion; for adjectives, the reverse held. He concluded that it was more feasible to posit a zero copula in adjectival environments than a contraction rule followed by deletion. The re-analysis thus illuminates a fundamental similarity with Caribbean English Creoles and a significant difference from other American English dialects.

Baugh's teaching career began in 1975 as Lecturer in Black Studies, Linguistics, Sociology, and Anthropology at Swarthmore College. He was appointed assistant professor at the University of Texas (Austin) in 1979, being chosen to strengthen the discipline of Sociolinguistics in what was then the second most highly-rated Linguistics department in the USA. There he teamed up with the anthropologist Joel Sherzer, to produce the edited volume *Language in Use* (1984).

Baugh joined Stanford in 1990, where he holds a joint appointment as Professor of Education and Linguistics. He was director of Stanford's Teacher Education program between 1994 and 1996. The term 'Educational Linguistics' aptly sums up Baugh's commitment to applying the insights of modern Linguistics and Sociolinguistics in educational and other societal contexts with methodological rigor. He has been a vocal yet sensitive participant in the Ebonics debate (see *Ebonics and African American Vernacular English*) bringing to bear his objective knowledge of social dialectology with a commitment to understanding the viewpoint of those most in need of help within the American schooling system. Out of this concern have come two books *Out of the Mouths of Slaves: African American Language and Educational Malpractice* (1999) and *Beyond Ebonics: Linguistic Pride and Racial Prejudice* (2000a). In the latter, Baugh sifts through the volatile circumstances and evidence that triggered the debate, including the origin of Ebonics. He also considers the legal, educational, and theoretical issues that still linger as part of the quest for racial reconciliation. In related work, Baugh examines policy related to the analyses

of the language of minority students, language equity and environmental change, and housing discrimination based on speech.

Baugh is a gifted lecturer, winning awards for teaching excellence at Texas and Stanford. He is a past president of the American Dialect Society (1992–4), and a past vice chair of the board of trustees for the Center for Applied Linguistics in Washington DC (1983–9), and an elected representative to the executive committee of the Linguistics Society of America (1998–).

Bernstein, Basil (1924–)

K. Rajagopalan

Basil Bernstein is a retired British sociologist with a brilliant academic career spanning several decades at the University of London. His ideas have had an impact not only on sociology but also on other areas,

such as linguistics and educational theory (see *Code, Sociolinguistic*). He is best known for his distinction between 'restricted code' and 'elaborated code,' proposed in order to explain the observed linguistic

differences between children of lower and middle classes. This distinction has come under scathing attack, (see *Social Class*) (often bordering on vilification) from several quarters.

1. Restricted vs. Elaborated Code

It is not at all easy to summarize Bernstein's distinction between restricted code and elaborated code for the simple reason that his ideas have evolved substantially over the years, sometimes resulting in terminological revisions. The two were initially referred to, respectively, as 'public language' and 'formal language' (Bernstein 1959). The key idea was that the children of socioeconomically underprivileged classes tend to speak in a way dependent on, and complementary to, the actual set of physical circumstances attending on the given communicative situation (public language), whereas the children of middle and upper classes had at their disposal a language (formal language) that was relatively free of the context of situation. It was argued that, since the formal language closely approximated the language privileged by the schools, these children had a head start right from the beginning (see *Home Language and School Language*).

By the mid-1960s, however, the new terminology, restricted code vs. elaborated code, replaced the old one. What had lent itself to being interpreted as a qualitative distinction between two varieties of a given language, all of a sudden seemed to point to a quantitative distinction between different manifestations of one and the same language. This gave rise to the perfectly understandable suspicion that Bernstein in effect endorsed a difference in the inherent capacities with which the children are endowed to begin with.

2. Major Influences

Bernstein's thoughts were, as he has himself acknowledged, influenced by Whorf, Sapir, Durkheim, Marx, Malinowski, Weber, Mead, Piaget, Luria, and Vygotsky, among others.

3. The Controversy in Retrospect

It seems important to register, in Bernstein's defense, that a good deal of the furore over his distinction most probably had to do with the unfortunate choice of the word 'code.' Although long familiar to sociologists, semioticians, and communication theorists, code was a fairly new term in linguistics where, thanks to the influence of Chomsky in the 1960s, the term had come to acquire the sense of a system of rules innately shared by all members of a speech community as part of their biological endowment. No wonder, then, that some of the sharpest criticisms of Bernstein's theory came from linguists of a Chomskyan persuasion.

Bickerton, Derek (1926–)

G. G. Gilbert

Derek Bickerton was born in Cheshire, UK. 'His father was an estate agent for Lord Leverhume and his mother was a teacher. His wife, Yvonne, who he met in Madrid where they were both living during the 1950s, is a psychologist specializing in marriage and family therapy. They have three children ...' (Byrne 1991). As well as gaining an MA in English literature in 1967 from Cambridge University and PhD from Cambridge in 1976 in linguistics, Bickerton has had a distinguished career as a writer (four novels, among many other works), journalist, EFL and linguistics professor, and creolist. Living and working for extended periods in Spain, Barbados, Ghana, Guyana, Lancaster, and Hawaii, he has also been a visiting professor and researcher at the University of Michigan, SUNY at Stony Brook, Universidade de Campinas (Brazil), Universidade Católica in São Paulo, Universidade Federale (Rio de Janeiro), University of Texas at Austin, Universiteit van Amsterdam, and the Université de Provence. In the early 1990s, he was professor of linguistics at the University of Hawaii.

In the field of creolistics, Bickerton is a skilled writer, an able linguist, and a proponent of important new ideas which convey strong claims about the nature of creole languages, first language acquisition, and the development of language over the entire historical span of the human race and its precursors. He is best known for his Language Bioprogram Hypothesis (which makes stronger and more specific claims than does Chomsky) about the nature of Universal Grammar, in its manifestation as a neurological structure, a product of biological evolution, genetically inherited, and forming an integral part of the human brain. Bickerton views creolization as the learning of a pidgin as a native language by children; the attendant extremely defective language input necessarily undergoes supplementation by the bioprogram, which is ordinarily suppressed during the course of normal (noncreole) first language acquisition. This suggests that researchers bent on linking the biological and structural (achronic) aspects of language turn their attention to creole languages. Bickerton thinks that it is the nature of the bioprogram that explains why certain creole structures (such as free morphemes, preposed to the verb, marking tense, modality, and aspect) recur so frequently, and why pidgins, which are not subject to the bioprogram, differ from each other so widely. The controversial and wide-ranging nature of claims such as these has drawn the attention of a large, general audience to Bickerton's writings. *Roots of Language* (1981) is 'the most widely cited and reviewed creole work yet produced ... [it] has received more than 200 reviews, three of which were in *Newsweek*, *The New York Times Review of Books* [*The New York Review of Books*], and *Discover'* (Byrne 1991: 3). Bickerton was the key figure in the rapid movement of creolistics to centerstage within general linguistics in the 1980s.

Blommaert, Jan (1961–)

K. Maryns

Jan Blommaert is, in the first place, a multifaceted researcher. The versatility which characterizes his work manifests itself in his varied interests: through his research in the domains of language, identity, and diversity, Blommaert has come to play a key role in the current fields of pragmatics, sociolinguistics, and ethnography.

Blommaert was born in Dendermonde, Belgium on November 4, 1961. He specialized in African studies at Ghent University (1979–1983) and linguistics at the universities of Antwerp and Amsterdam (1984–1986). He received his PhD from Ghent University in 1989 with a dissertation in African studies on Kiswahili political style. From 1988 until 1991 he worked as an assistant at Ghent University and he spent the following six years of his career as research director at the Pragmatics Research Center of the University of Antwerp. In 1997, he was appointed as a professor of African linguistics and sociolinguistics at Ghent University.

Blommaert's initial work was closely tied to relations between language policy and planning in Tanzania on the one hand, and grassroots language behavior on the other. Through his concern with Kiswahili political discourse, language mixing, diversification and its impact on modern African political style, Blommaert developed an interest in the pragmatics of intercultural communication. It is in this context that Blommaert widened his concern with language politics in Africa to the pragmatics of minority politics in Belgium. Together with Jef Verschueren, Blommaert has done significant work on immigration, nationalism, and racism in Belgium, as well as on the impact of ideology in the

field of migration. Blommaert is co-editor of the *Handbook of Pragmatics* (Benjamins, since 1995). A theoretical spin-off of these concerns with language politics in Africa and Belgium is his research interest in language ideologies. In 1997 *Political Linguistics* was published (co-edited with Chris Bulcaen) and in 1999 Blommaert edited a series of studies on 'Language Ideological Debates' (Mouton de Gruyter) in an attempt to formulate some ways in which sociolinguistics and history could be blended in the analysis of language-ideological processes.

Blommaert's linguistic work is deeply interlaced with ethnographic, anthropological, and sociological concerns. In fact the motivation behind most of his projects can be traced back to a longstanding interest in linguistic diversity or even 'impurity' of languages. The connection between linguistic diversity and inequality develops itself as a thread throughout Blommaert's work, one of the central objectives of which is to arrive at a better theoretical and empirical understanding of language in social life, investigating inequality as it is reflected in a materialistic view of language as a resource in people's lives. In this context Blommaert continued work on linguistic resources and inequality in narrative, as reflected in his current concerns with grassroots literacy in the Congo and narratives of African asylum seekers in Belgium. Blommaert founded an international research group sponsored by the Belgian National Science Foundation on 'Language, Power, and Identity' in which these concerns with linguistic inequality are further explored.

Boas, Franz (1858–1942)
R. Darnell

Franz Boas was the founder of North American anthropology as it is known in the late twentieth century. He insisted on a scope which included ethnology, linguistics, archaeology, and physical anthropology and contributed seriously to each of these subdisciplines. In practice, however, his emphasis was on the urgent salvage task of recording the languages and cultures of native North America. He eschewed the premature theoretical speculations of the classical evolutionists in favor of a diffusionist historical anthropology with a strong empiricist component.

Boas was born in Minden, Westphalia, Germany on July 9, 1858. He received his PhD from the University of Kiel in 1881 with a dissertation in physics on the color of sea water. During a year of Eskimo fieldwork in Baffin Island, his interests shifted from geography to culture. After a year at the University of Berlin, he moved to the USA. He served as associate editor of *Science*, taught at Clark University, organized anthropology exhibits at the Chicago World's Fair from 1892–95, and began a lifelong study of the Indians of the northwest coast, particularly the Kwakiutl and Tsimshian.

In 1899, he joined the faculty of Columbia University which he built into the primary center in the USA for the training of professional anthropologists. By about 1920, his first generation of students held the major positions in the discipline, which was becoming increasingly academic in its institutional base. Boas became Professor Emeritus in 1937 but continued to be active in Columbia anthropology until his death in 1942.

Boas edited the *Handbook of American Indian Languages* for the Bureau of American Ethnology. His introduction to the first volume (1911) emphasized the analytical discreteness of race, language, and culture as classificatory variables in anthropology and insisted upon deriving grammatical categories from the languages studied rather than from Indo–European theories of grammar. The *Handbook* contained brief grammatical sketches intended to be comparable in format and illustrative of methods of linguistic description.

Boas's own linguistic work was closely tied to ethnology. He proposed a shared database for linguistics and ethnology of texts in the words of native speakers. Linguistic analysis would produce texts, grammars, and dictionaries. Cultural content of the texts would be mined in relation to data observed in the field. Boas's own work, particularly on Kwakiutl and Tsimshian, exemplified the method. Generations of ethnologists trained by Boas combined linguistic work with their cultural analyses.

851

Boas's contributions to historical linguistics were less significant. He taught himself linguistics in order to use it in his fieldwork and never studied comparative philology in any formal way. He was ultraconservative about the demonstration of genetic relationship because he believed its effects could not be distinguished from those of borrowing. His model was historical reconstruction based on borrowing of folklore elements on the northwest coast. Consequently, he opposed the genetic reconstructions of Edward Sapir (see *Sapir, Edward*) and others of his former students.

More than any other single person, Boas was responsible for the corpus of descriptive material on native American languages and for the inclusion of linguistics within North American anthropology.

Bourdieu, Pierre (1930–)

C. B. Vigouroux

Pierre Bourdieu belongs to the generation of French intellectuals—including Barthes, Foucault, Lacan, Levi-Strauss, and Derrida—who were greatly interested in the structuralist thought of the 1960s. He seeks to bring together different disciplines in order to explain diverse aspects of society. The aim of his work on a range of issues such as fashion, consumer practices, museum going, the student world, etc., is to unveil the logic of domination within these social practices. Three key axes run through Bourdieu's work: theory, practice, and reflections on his own discipline.

Born in 1930 in the southern French town of Denguin (Pyrénées-Atlantiques), Bourdieu entered the prestigious *Ecole normale supérieure* at the age of 21. Having passed the agrégation (the highest competitive academic examination in France) in philosophy in 1955, he left for Algeria where he worked as an assistant lecturer at the University of Algiers. His first publications were concerned with the social transformation of Algeria (e.g., *Sociologie de l'Algérie*, 1958). Back in France he taught at the Sorbonne and for some time at the University of Lille (1961). In 1964 he was named *Directeur d'Etudes* at the *Ecole Pratique des Hautes Etudes* (now the *EHESS*). His first works on the French education system (*The Inheritors, French Students and Their Relation to Culture*, 1964 with J. C. Passeron) and on cultural practices in France (*Un art moyen*, 1965) date from this period. Bourdieu shows how the school system produces social inequalities and reproduces cultural privileges. Later, the French philosopher and sociologist Raymond Aron offered him the post of codirector of the *Centre Européen de Sociologie Historique*. Following a breakdown in relations between these two in 1968, Bourdieu set up his own research center and duly founded his own school of sociological thought. It is within this perspective that he launched his review *Actes de la recherche en sciences sociales*, in 1975, in which he wrote an impressive number of articles on various topics. In 1979 he published a major work, *La distinction*, in which he analyses the historical and social genesis of esthetic taste. Two years later he was rewarded for his work by being offered the post of chair in sociology at the highest French academic institution, the *Collège de France*. Having built up a reputation in France, Bourdieu turned his mind to the international intellectual scene (in collaboration with the Universities of Princeton and Pennsylvania in the USA). In 1981 he grouped together a collection of articles on language (*Ce que parler veut dire*), some of which had previously been published, in an original approach aiming to uncover the hidden structures of society via language.

The 1990s mark a turning point in Bourdieu's works, as social theory is transformed into social action. *La misère du monde* (1993) (a series of interviews with underprivileged groups of French society conducted by Bourdieu's team) demonstrates his desire to bring sociology to the heart of political struggles. He has been involved with numerous social causes (successive strikes in December 1995, protests by the jobless in January 1998 or support for Algerian intellectuals) and created the association 'Raisons d'agir,' along with the review 'Liber,' with the intention of opening up the social sciences to a larger public, publishing short works on diverse

topics, such as the media, the intellectual world, etc.

Pierre Bourdieu's last lecture at the *Collège de France* (Spring 2001) was a personal account of his own sociological work and intellectual journey. His overall contribution, far from being restricted to the social sciences, invites us to rethink the world in which we live: whether one agrees or disagrees with Bourdieu, he remains a key intellectual figure.

Bright, William (1928–)

B. B. Kachru

William Bright was born in Oxnard, California. He received an AB in linguistics from the University of California at Berkeley in 1949 and a PhD in linguistics in 1955 for his study of the Karok language (published in 1957, *A Grammar of the Karok Language*). At Berkeley, Bright was initiated into the 'spirit of the Sapir tradition' (see *Sapir, Edward*) by Emeneau (see *Emeneau, Murray Barnson*) and Mary R. Haas, and later by his colleague Harry Hoijer. A Rockefeller Foundation Fellowship (1955–57) took Bright to India for teaching and research at Deccan College, Poona (now Pune). In confronting South Asia's sociolinguistic realities, Bright (1976: 271) observes that it 'was an area where the phenomena of language contact and linguistic area... and the sociolinguistic phenomena of language variation were impossible to ignore.' In India, Bright's interaction with Gumperz (see *Gumperz, John J.*) inspired him to explore the role of these sociolinguistic phenomena in language history.

Bright started his teaching career at the University of California at Los Angeles in 1959 as Assistant Professor, then Associate Professor in 1962 and Professor in 1966. He is an inspiring educator, who has trained many distinguished scholars in sociolinguistics and other branches of the linguistic sciences from Asia, Africa, Europe, and the United States. He retired to become Emeritus Professor of Linguistics and Anthropology in 1988 and is now Professor Adjoint of Linguistics in the Department of Linguistics, University of Colorado, Boulder.

Bright has held a variety of editorial positions in scholarly journals and reference volumes, including, *International Journal of American Linguistics* (1963); *Handbook of Latin American Studies* (1963–66); *Language* (1965–87); *International Encyclopedia of Linguistics* (1992); *Language in Society* (1992–99); founder-editor, *Written Languages and Literacy* (1997–); founder-editor, *Oxford Studies in Anthropological Linguistics* (1992).

Bright's peers in the profession have honored him in many ways: as the president of the Linguistic Society of America (1989), of the Society for the Study of the Indigenous Languages of the Americas (1995), and of the Dravidian Linguistic Association (1996), and as a recipient of important Fellowships (American Council of Learned Societies (1964–65) and the Guggenheim Foundation (1972)). A festschrift, *The Life of Language: Papers in Honor of William Bright* was edited by Jane H. Hill, P. J. Mistry and Lyle Campbell (1998).

Bright's scholarly work has contributed insights and fresh cross-cultural and cross-linguistic data (Amerindian and South Asian languages) to theoretical, methodological, and descriptive studies in a variety of fields: language variation; American Indian languages; language and culture; onomastics; Dravidian studies; and lexicography. Bright's other interests include writing poetry, e.g., 'Eight poems' in *Linguistic Muse* (Napoli and Rando (eds.) 1979). He also edited *Word Formations: Poems by Linguists*. A few of his many publications are cited in the bibliography.

Cameron, Deborah (1958–)

S. S. McRae

Deborah Cameron is currently Professor of Languages in Education at the Institute of Education, University of London, where she teaches MA modules on linguistic description, and on discourse and culture. Her academic career began in London in 1983, teaching English language and linguistics at what was then the Roehampton Institute. Before taking her current position at the University of London, Cameron spent eight years in the English department of Strathclyde University in Glasgow, Scotland. She started as a Senior Lecturer in their program in Literary Linguistics; in 1997 she became Professor of English Language.

Cameron's research interests are wide, and include sociolinguistics, discourse analysis, educational linguistics, media and cultural studies, language ideologies, feminist theory, and language and gender. It is for her work in the latter two areas, language and gender and feminist theory, that Cameron is best known. Among her many publications in these fields is her seminal book *Feminism and Linguistic Theory* (1992), in which she provides a critical introduction to developments in the study of language and gender. This theme is continued in *The Feminist Critique of Language* (1998), a collection of papers edited by Cameron. This collection, as well as serving as an introduction to directions and debates in feminist thinking, also looks at the historical background of feminist ideas about language. Cameron has also contributed to several collections concerned with current preoccupations in language and gender research (see Cameron 1996).

Although primarily associated with language, gender, and feminist linguistics, Cameron is also widely published in other areas. For example, in her popular book *Verbal Hygiene* (1995) she looks at attitudes towards language and the attempts made to regulate its use. More recently, Cameron has become interested in the discourse about 'communication skills.' In *Good to Talk? Living and Working in a Communication Culture* (2000) she explores the social and political implications of communication training. Cameron's most recent book, *Working with Spoken Discourse* (2001), reflects her continued interest in the analysis of talk, an area covered in an earlier publication, *Analysing Conversation*, co-authored with Talbot Taylor (1987).

Coates, Jennifer (1942–)
S. S. McRae

Jennifer Coates is currently Professor in English Language and Linguistics at the University of Surrey, Roehampton, London. Her academic career began in 1969, as a Research Assistant at University College, London, working on the Survey of English Usage. Following this, she was a Research Fellow in the Department of Linguistics at the University of Lancaster. In 1980 she was awarded a PhD from Lancaster for her research on the semantics of the modal auxiliaries. Three years later, Coates' thesis was published in book form, the first of many publications.

It was Coates' subsequent book, *Women, Men, and Language* (1st edn. 1986, 2nd edn. 1993), which reflected a shift towards a more sociolinguistic perspective. More specifically, it signaled the beginnings of her renowned work on language and gender. At that time, the relationship between language and gender was of minority interest. Coates carried out pioneering work in the area, focusing initially on the particularly neglected area of all-women talk. She investigated linguistic strategies used by women in their friendship groups, and found that women's communicative style tended to be cooperative, typified by solidarity-building interactive support and collaboration. A recurrent theme of Coates' work is her concern that this preference by women for a cooperative discourse style reinforces unequal power divisions between women and men, given men's apparent preference for a more competitive discourse style.

In line with current preoccupations in language and gender research, Coates' more recent work emphasizes the variable nature of masculine and feminine identities. Coates' abiding interest in narrative practices explores the role of talk in the construction of these identities, and she is currently extending the focus of this interest to include work on story-telling in men's, as well as women's, conversation. Coates' more recent work also reflects her continued interest in the cooperative nature of women's talk (see in particular Coates 1997b), and she is at present involved with Bristol University in ground-breaking research into the collaborative talk of deaf women friends.

Cooper, Robert Leon (1931–)
B. Spolsky

Trained originally as an educational psychologist, Cooper has essentially mapped the sociolinguistic aspects of educational linguistics, showing the need to incorporate social dimensions in the notion of language ability, and spelling out the place of language educational policy (which he labeled

'language acquisition planning') as a critical element in the social changes associated with language planning.

After undergraduate training at Harvard and graduate study at the University of Pennsylvania, he studied educational psychology with Thorndike and MacGinitie at Teachers College and Columbia, respectively. From 1966 to 1968, he worked with Joshua Fishman (see *Fishman, Joshua*) on the epoch-making study of bilingualism in the New Jersey *barrio*. His seminal paper 'An elaborated language testing model' drew on that experience. It was the first clear statement that language testing and teaching needed to take into account the communicative competence proposed by Dell Hymes (see *Hymes, Dell Hathaway*) rather than the rigorous but more narrowly focused notion of linguistic competence being espoused by Noam Chomsky and his followers.

Cooper then spent a year working with the pioneering Ford Foundation sponsored study of language in Ethiopia. There, alone with Charles Ferguson (see *Ferguson, Charles A.*), J. Donald Bowen and M. L. Bender, he helped trace the goals for language policy and language education in a complex multilingual society.

After teaching at Yeshiva University, Stanford University, and California State University, Cooper moved to Israel in 1972 to join Fishman again for the first major study of the spread of English. He remained in Israel, and for the rest of his academic career, he was a professor in both education and sociology at the Hebrew University, where he trained students and carried out sociolinguistic research that helped bridge the fields of sociolinguistics and education.

He coedited two key collections of papers on bilingual education in the late 1970s. In the late 1980s, he codirected a sociolinguistic survey of the Old City of Jerusalem. His magisterial *Language Planning and Social Change* (Oxford University Press) 1989 rounded out a career of research and publications that have established the key relationships between sociolinguistics and educational linguistics.

Since retirement, Cooper has been traveling and writing about travel, with a special interest in Mark Twain and the South Pacific.

Cummins, Jim (1949–)

C. Baker

James (Jim) Patrick Cummins was born on July 3, 1949 in Dublin, Ireland, encountering bilingual education at an Irish Gaelsciol at the age of seven. After graduating in Psychology from University College Dublin in 1970, he completed his PhD at the University at Edmonton. He then held posts at St. Patrick's College, Dublin, and the Center for the Study of Mental Retardation at the University of Alberta included investigating special needs education for bilingual children—a theme that produced an influential book in 1984 entitled *Bilingualism and Special Education: Issues in Assess-*

ment and Pedagogy. Since 1978, he has been a Professor in the Modern Language Center at the Ontario Institute for Studies in Education in Toronto, Canada.

His voluminous writing addresses many interdisciplinary topics including cognition, cultural diversity and multiculturalism, bilingual education, the theory of bilingualism, empowering minority language children through information and communication technology (ICT), language assessment, reading instruction, immersion education, reading difficulties, mother tongue maintenance, metalinguistic

awareness, immigrant children, language proficiency, special needs children, the Ireland and Canada context, and the relationship between anglophone and francophone communities in Canada. He is particularly noted for the following:

(a) making a distinction between Basic Interpersonal Communicative Skills and Cognitive Academic Language Proficiency (BICS and CALP);

(b) the Separate Underlying Proficiency (SUP) model of bilingualism and the Common Underlying Proficiency (CUP) model of bilingualism;

(c) the Thresholds Theory which posits levels of linguistic competence that a bilingual child must attain both to avoid cognitive deficits and allow the potentially beneficial aspects of becoming bilingual to influence cognitive functioning;

(d) the Developmental Interdependence Theory which suggests that growth in a second language is much dependent on a well-developed first language;

(e) the linguistic mismatch hypothesis;

(f) the 'time on task' hypothesis;

(g) the iceberg representation of language proficiency with the fusion of two languages in the cognitive systems of a child 'beneath the surface';

(h) two dimensions of communication: cognitive demanding/undemanding; context reduced/embedded;

(i) a theoretical framework for the empowerment of minority language students that accounts for dominant/dominated power relationships, culture, community, pedagogy, and assessment; and

(j) the embeddedness of academic language development, and schooling generally, in a nexus of societal power relations that provides a strong argument for developing critical language awareness among students, and for minority language students to explore issues of cultural identity, critical enquiry, and knowledge generation.

Over three decades, there has been a progression from early interests in psychology, cognitive development, assessment, and psychometrics to more sociopolitical ideas. There has also grown a realization that to effect change among policy makers and politicians, among teachers and school districts, both understanding and addressing those politics is essential. Thus there has been a considerable personal involvement with policy makers and practitioners. His long association with the Californian State Education Department and the California Association for Bilingual Education (CABE) symbolizes this leadership in political activism. The involvement with CABE has meant valuable interaction with practitioners and crucial political issues such as equity, tolerance, empowerment, collaborative relationships, and critical pedagogy.

Das Gupta, Jyotirindra (1933–)

L. M. Khubchandani

Jyotirindra Das Gupta (b. 1933), Professor Emeritus of Political Science, University of California, Berkeley, has worked extensively on the issues of language development and ethnicity, particularly in the context of multicultural federal polities.

Originally from East Bengal (now Bangladesh), his early education was in Calcutta; he graduated from Calcutta University in 1955. As a student activist he edited a journal, *Anvil*. Since the early 1960s, Das Gupta has been associated with the Center for South and East Asia Studies, University of California; he received his doctorate from the University of California in 1966, and retired from the same University in 1995.

Das Gupta's studies extend over nearly four decades and are wide-ranging, making a significant contribution to the field of language politics and national reconstruction. In particular they bring under a close purview the issues of languages rivalries and political integration (1970), language as a 'societal resource' and the 'decision-making' models in language planning (1972), relation of language and ethnicity in a democracy (1991), community's autonomy and institutional development in a

857

multicultural state (1997), and India's federal design contributing to pluralism (in press).

As a member of the international project sponsored by the Ford Foundation during the late 1960s, Das Gupta worked extensively on language problems and language policies in developing countries; he jointly edited two volumes on the processes of language planning (1968, 1977). Later his focus shifted to the study of ethnicity in multicultural societies, particularly in the context of India's northeast parts.

Language plays a crucial role in the reorganization of institutions; it is inseparable from such activities as planning, propaganda, and evaluation. Das Gupta's studies have amply succeeded in dispelling the myth that language politics belongs to the realm of 'uncivil' politics. His systematic appraisal of the empirical evidence concerning decision-systems developing in the federal set-up in India convincingly shows that democratic institutions make it possible to work out language policies that contribute to pluralism—an alternative model of integration. This assessment conclusively rejects the despairing view prevailing among many political observers such as Gunnar Mrydal and Selig Harrison about the futility of democratic operations in the development of a multicultural nation.

Upholding the basic premise in Sociolinguistics that *variation* pervades all nature, including human nature, Das Gupta assumes basic compatibility between language differences and multicultural nationalism: '(these) contribute in promoting a form of nationalism that is different from the West.' He also challenges another assumption when language is usually dismissed as a 'primordial' question; primordial groups are considered to be retarding political modernization. Das Gupta argues that the very nature of language politics permits a special degree of flexibility: 'These conflicts, more often than not, have proved to be the schools of bargaining and negotiation' (1970: 269).

Das Gupta provides a wealth of material on language as an 'institution' when discussing, at length, the issues of the Assamese language policy and its conflict with tribal languages in north-east

India (1997). He supports the conviction that *particularistic* loyalties (on ethnic, religious, and language issues) are not necessarily inconsistent with *national* loyalties.

Many studies in language policy-making and language planning seem to imply the *handicap* model in pursuit of development (Khubchandani 1997). Das Gupta's pathbreaking explorations in India's northeast draw our attention to the language *assets* in traditional speech communities representing rich oral cultures. This can have a significant bearing on a long-term view of the issues concerning the *quality* of human communication in a changing society.

DeCamp, David (1927–79)

R. Le Page

David DeCamp was born in Michigan, USA. He completed his MA in 1949 at the University of New Mexico and his PhD in 1953 at Berkeley. An abridged version of his dissertation *The Pronuncia-*

tion of English in San Francisco was published in Orbis in 1958–59. DeCamp went to Jamaica in 1957 with his wife, Sally and three small children as Fullbright Senior Research Fellow working under

Le Page (see *Le Page, Robert*) on The Linguistic Survey of the Caribbean. DeCamp took to Jamaica like a duck to water and had two fruitful years of collaboration with Le Page, Beryl Bailey and Frederick Cassidy. He helped organize the first International Conference on Creole Language Studies at UCWI (University College, West Indies). He then joined the University of Texas at Austin in 1959, teaching in the English department. He continued to work on the recordings he had made in Jamaica for the rest of his relatively short life. From this data base came a number of papers of the Creole language of Jamaica, none perhaps better known than *Towards a Generative Analysis of a Post-Creole Continuum*. He was one of the first to apply the term 'post-creole continuum' to the language situation of Jamaica; and certainly the first to propose the adaptation of the Guttman implicational scalogram (see *Scaling*) to cope with the description of such situations in dynamic terms, providing an alternative to Labov's variable rules (see *Sociolinguistic Variation*). He labored to apply his polylectal model to his own data, working always with meticulous care, but wrote to Le Page not long before his death that he was sorry that the idea had been taken up so avidly as he had never been able to scale more than 30 percent of his Jamaica data. Nevertheless his paper has spawned legitimate work not only in creolistics but in the study of second language acquisition too (Dittmar 1980).

DeCamp was responsible for attracting other distinguished creole scholars to Texas. He was one of the co-editors of the *Bibliography of Pidgin and Creole Languages* (1975) working under Reinecke (see *Reinecke, John*) to produce the major reference work in the field. He was also an early member of the Society for Caribbean Linguistics and a regular attendee at its meetings. From 1974-76 he was Associate Director for International Programs at the Center for Applied Linguistics, and from 1973–79 had a favorite summer connection as lecturer in Linguistics at the Middle East Linguistics Institute in Tunis, while continuing to serve as professor of English, Linguistics, and Education at the University of Texas at Austin.

DeCamp's contributions were not only in Creole Studies and variation theory, but also in English, Chinese, and the teaching of English as a Second Language (TESL). In addition to a variety of Linguistics courses, he taught courses in such diverse areas as Creative Writing, Mandarin Chinese, TESL, the History of the English Language, and English Literature. In 1964 he was a Senior Linguistic Specialist in Taipei, Taiwan, advising the Chinese Ministry of Education and assisting in the preparation of materials for the teaching of English in Chinese secondary school. Between 1964 and 1966 he was Director for courses in Chinese and Japanese at Texas, and was also Principal Investigator for a research project in Chinese-English lexicography. Beginning in 1961, he also served as lecturer and linguistic consultant to 13 Peace Corps Training Projects.

When he died on October 17, 1979, DeCamp left a wife and four children, and a wealth of scholarly ideas and insights. His untimely death, I am sure, robbed us of some major published work.

Dittmar, Norbert (1943–)

P. Schlobinski

Norbert Dittmar is the most well known German sociolinguist, who renewed traditional German dialectology by integrating it with the variationist work of William Labov. In his work, he combines different fields of linguistics and sociology, such as formal grammar, language acquisition, rhetoric, social

psychology, ethnomethodology, and discourse analysis. In practice, however, he focuses on empirical linguistics, focusing on urban varieties, second language acquisition, and German as a spoken language.

Dittmar was born in Bielefeld, Westphalia, on March 4, 1943. He studied philosophy and German as well as Slavic and Romance languages and received his PhD from the University of Konstanz with a dissertation on sociolinguistics, published in 1973 (English 1976). From 1974 to 1978 he worked at the University of Heidelberg on a research project known as 'The Heidelberg Project on Pidgin German of Foreign Workers' together with Wolfgang Klein. Since 1979 he has been a professor at the German Department of the Free University of Berlin.

During his work at the Heidelberg project he applied the so-called 'variety grammar' (which was developed by Wolfgang Klein) on syntactic features of the German language as spoken by Spanish and Italian migrants. The results were published in 1979 and have very much influenced subsequent studies on syntactic variation within the Labovian framework. Shortly after Dittmar became professor at the Free University of Berlin he started his work on the Berlin urban vernacular together with Peter Schlobinski and Inge Wachs. The project focused (a) on the description and explanation of the Berlin dialect, in particular the effect of the division of the speech community has for the socially and politically distinct subcommunities; (b) on language attitudes; and (c) on the description of the stylistic and rhetorical devices of the Berlin vernacular register which is called *Berliner Schnauze*. After the Berlin Wall was torn down, Dittmar did research in Berlin and Brandenburg regarding the question how the Berlin dialect in East and West will merge. For this research he expanded correlative sociolinguistic approaches into functional approaches. Apart from his sociolinguistic research, Dittmar has been in charge of projects on intercultural communication, second language acquisition, learner varieties, and therapeutic discourse since the beginning of the 1980s. Today, his main interest lies in the field of syntax and semantics of spoken language. Dittmar is responsible for the database of German as a spoken language at the Free University of Berlin. This database includes corpus description as well as analysis.

Dittmar's work was published in different languages. He was editor of the series *Sociolinguistics and Language Contact* (Walter de Gruyter) and is a member of the editorial board of *Linguistics* and *Linguistische Berichte*. Together with Ulrich Ammon and Klaus Mattheier he is editor of the *Handbook of Sociolinguistics* (Walter de Gruyter).

Dorian, Nancy (1936–)

S. Romaine

Nancy Dorian graduated from Connecticut College for Women in 1958 with a major in German. After completing her PhD in Linguistics at the University of Michigan in 1965, she joined the German Department at Bryn Mawr College in Bryn Mawr, Pennsylvania.

Her dissertation fieldwork on the Scottish Gaelic dialects spoken in the East Sutherland villages of Brora, Golspie, and Embo, ultimately led to her pioneering work on language obsolescence. In the course of conducting what she had anticipated to be a rather routine traditional dialect study under the auspices of the Gaelic Division of the Linguistic Survey of Scotland at the University of Edinburgh, Dorian was confronted with a complicated picture of variability and on-going change. Realizing that the uniqueness of the varieties of Gaelic and knowledge of the fisherfolk who spoke them were soon to disappear as the language was no longer being transmitted, she made the documentation of the dialects and local lifeways her life's work. Her 1981 monograph detailed the changes occurring in East Sutherland Gaelic in sociohistorical perspective at the same time as it laid the theoretical foundations for the study of language obsolescence. A subsequent edited volume (Dorian 1989) brought together a collection of papers from researchers working in a variety of language shift settings around the world, with invited commentaries from specialists in related fields such as creolistics, historical linguistics, and

860

second language acquisition, to address issues from a comparative perspective.

In addition to the work in East Sutherland, Dorian also conducted fieldwork on the variety of Pennsylvania German spoken in Berks County, Pennsylvania. After disability rendered her unable to do field-work *in situ*, she continued to carry out her investigations through taped correspondence, recorded telephone conversations, and personal visits from villagers to her home in the US.

Within the field of language obsolescence Dorian is especially known for her notion of 'tip' in which language transmission abruptly ceases in seemingly sudden fashion, as well as the problem of 'personal pattern variation,' i.e., a high degree of individual variability unaccountable for in terms of the usual social factors like class, sex, region, network, etc. invoked by sociolinguistics to explain variation (Dorian 1986, 1994). Other papers have addressed a variety of methodological and theoretical issues concerning endangered languages. Since 1987 she has edited a section of the *International Journal of the Sociology of Language* entitled 'Small languages and small language communities.'

Edwards, John Robert (1947–)

W. F. Mackey

John Robert Edwards (born in Southampton, UK, on December 3, 1947) studied in Canada at the University of Western Ontario and at McGill University (PhD in Psychology, 1974). From his basis in social psychology, he has investigated the many unexplored facets of plurilingualism, especially as they relate to ethnicity, education, identity, and nationalism. His best work is based on broad comparative studies with evident cross-disciplinary expertise. Notably, he addresses questions hitherto unheeded in the field of social psychology, as, for example, the psychological basis of the prescriptive urge, leading to a theoretical framework on which to attach the phenomenon of prescription. This has enriched his work on language academies, which may well be regarded as unique, since it constitutes an overall, interdisciplinary, descriptive, historical, and theory-oriented study.

Edwards has shown that, through group markedness, all varieties of language can possess solidarity value. The use of these varieties (including social dialects) in education can lead to a desire to purify them. Purism can become a social impulse. It promotes the acquisition of knowledge about the language, which in turns strengthens and refines attitudes toward it.

Placing himself at the intersection of social psychology and studies on nationalism, Edwards has been able to describe the mechanisms used in the construction of national identity. Appeals to the imagination engender changes in the perception of language within group identity triggering feelings of belonging. Much of the logic of language planning is calculated to touch the emotions through the promotion of value-laden opinions. Such language promotion can be a reflexion of political power.

To arrive at conclusions of such depth and scope, Edwards had to become familiar with a number of other language-related disciplines, like political philosophy, sociology, education, and linguistics for, as his work well demonstrates, language-phenomena cannot be comprehended within the paradigms of a single discipline.

That is why his publications have been able to embrace such issues as diverse as language policy, language identity, language revival, ethnicity, nationalism, prestige, and pluralism—all of which can be found within the pages of more than a dozen of his books. Notable among these are: *Multilingualism* (1994), *Language, Society, and Identity* (1985), and *Language and Disadvantage* (1979).

Much of Edwards' thought can also be found in his introductions to the many important books he has edited, like: *Language in Canada* (1998), *The Irish Language: An annotated Bibliography of Sociolinguistic Works (1772–1982)* (1983).

His skilled editorship of the Multilingual Matters Book Series has also contributed to the propagation of new knowledge in language identity, language insecurity, language planning, minority, and aboriginal languages.

Yet to appreciate the scope of his contribution to these important language-related issues one must turn to the content of more than 100 of the articles and invited lectures on sovereignty, separatism, parochialism, language stigma, sex-traits, language prestige, elaborated and restrictive codes, constructed languages, ethnic salience, Irish speakers, cross-national stereotypes, to name just these.

John Edwards is editor of the *Journal of Multilingual and Multicultural Development*, editorial advisor to a number of academic journals, a member of a dozen learned societies and a fellow of The Royal Society of Canada.

Emeneau, Murray Barnson (1904–)
W. Bright

Born in Lunenburg, Nova Scotia, on February 28, 1904, Emeneau is well known as an anthropologist and Indologist as well as a linguist. His doctoral degree from Yale, in 1931, was in Classics and Sanskrit; however, his postdoctoral studies with Edward Sapir (see *Sapir, Edward*) involved him in what was to become known as 'linguistic anthropology.' After carrying out three years of fieldwork with the Toda, Kota, and other Dravidian tribal peoples of south India (1935–38), he became one of the most eminent participants in the Sapirian tradition. As professor of Sanskrit and general linguistics at the University of California, Berkeley, he was founder–chair of the Department of Linguistics at that institution in 1953; since 1971, as Emeritus Professor, he has continued to work and publish prolifically.

Emeneau is famous for the breadth of his interests, which include ethnography, descriptive and historical linguistics, Sanskrit, comparative Indo–European, and Dravidian; he has done pioneering research in ethnosemantics, sociolinguistics, and oral literature. Within Indology, he has consistently pursued a vision of the integrated study of culture, language, and verbal art: he has written that his background led him to take a holistic view of India in which everything was of interest, and was fitted so far as possible into one large picture. During World War II, under military auspices, he taught Vietnamese and wrote a grammar of that language. Finally, continuing an interest in the Native American languages which he had studied with Sapir, he was responsible for initiating the Survey of California Indian Languages at Berkeley, and for inspiring several academic generations of field-workers in the area of Native American linguistics.

Emeneau is especially known for his research on the concept of the *Sprachbund* or 'linguistic area,' a geographical region in which a number of languages (apart from possible genetic relationship among them) have come to share borrowed linguistic traits. Emeneau's demonstration of the phenomenon in South Asia was, as he has said, 'essentially an injection of ethnological thinking into diachronic linguistics'; it has provided a model for studies in other parts of the world, and strongly influenced conceptions of historical relationship among languages.

Fairclough, Norman (1941–)
H. Janks

Norman Fairclough is the Professor of Language and Social Life at Lancaster University. He completed his undergraduate studies and Master's degree at London University and then worked for three years at

University College London. In 1996 he joined Lancaster University, where he was awarded his doctorate for his published work. He received an honorary doctorate from the University of Jyvaskyla in 1996.

He is best known for his book *Language and Power* (1989) in which he shows how language is used to maintain and reproduce existing relations of power in situated contexts. His work is important because of the ways in which he brings linguistic theory, discourse theory, and social theory together to establish connections between language, ideology, and power.

For Fairclough, language is also a means for contesting relations of domination and his sociocultural theory of language allows for human agency and creates possibilities for changing both language and social practice. He sees language as both a site of, and a stake in, social, institutional, and political struggle. In *Discourse and Social Change* (1992b) he considers the social factors that lead to the problematization of conventions, to innovation and to discursive change and he shows how such changes can conserve or transform existing relations of power. In *Critical Language Awareness* (1992a), for example, he shows the conservative force of 'appropriateness,' how it is tied to normalizing conventions and how it favors the language of socially powerful groups in the struggle for control over the sociolinguistic order.

Fairclough's work has been widely taken up because he offers both a method for critical discourse analysis and demonstrations of this method in practice. His method consists of three inter-related processes of analysis, tied to three inter-related dimensions of discourse. These three dimensions of discourse are:

(a) the object of analysis (verbal, visual, multi modal, multimedia texts);
(b) the processes by means of which the object is produced (written, spoken, designed) as well as received (read/listened to/viewed) by human subjects; and
(c) the sociohistorical conditions which govern these processes.

According to Fairclough each of these dimensions requires a different kind of analysis:

(a) text analysis (description);
(b) processing analysis (interpretation, including intertextual analysis);
(c) social analysis (explanation).

His approach enables analysts to focus on the signifiers that make up the text, to recognize the historical determination of their selection, and to understand how choices are tied to the conditions of possibility of the text's utterance.

In *Critical Discourse Analysis* (1995a), *Media Discourse* (1995b), *Discourse in Late Modernity* (1999), and *New Labour, New Language?* (2000), Fairclough applies his theory and his method of critical discourse analysis to language as social practice in both local and global contexts. He provides analyses of, amongst other things, the marketing discourse of universities, political speeches, popular television programs, speech reporting, police interviews, doctor–patient interactions, international neoliberal discourse, and the language of government.

It is in his critical discourse analysis that Fairclough's theory is grounded in practice. His leadership in the area of Critical Language Awareness and his contribution to theorizing Multiliteracies have also made an important contribution to work in education.

Fasold, Ralph W. (1940–)

W. Wolfram

Ralph W. Fasold is one of the pioneers of variation studies as this subfield developed in the United States in the 1960s and 1970s. His interests in sociolinguistics and linguistics, however, are much broader than the quantitative study of systematic variability, and his sociolinguistic practice has

extended from the study of variable phonetic detail to the consideration of language policy and vernacular language literacy. At the same time, his focus on linguistic structures has ranged from nominals in Thai to invariant *be* in African American Vernacular English. He is perhaps best known for authoring what are arguably the most comprehensive textbooks on sociolinguistics to appear in the latter half of the twentieth century, *The Sociolinguistics of Society* (1984) and *The Sociolinguistics of Language* (1990).

Fasold was born in Passaic, New Jersey, on April 8, 1940, and received his PhD from the University of Chicago in 1968 with a dissertation on noun compounding in Thai. In 1967, he joined the Urban Language Program at the Center for Applied Linguistics, directed at the time by his former undergraduate mentor, Roger W. Shuy. During the 1960s and early 1970s, the Center for Applied Linguistics was at the forefront of studies of urban dialectology in general and African American Vernacular English in particular. The staff conducted intensive field-initiated research studies in Washington, DC, and Detroit, Michigan, and the Center for Applied Linguistics initiated the first book series in sociolinguistics, the Urban Language Series. Fasold edited several volumes in the series (which featured Labov's *The Social Stratification of English in New York City* (1966) as its first publication), and authored *Tense Marking in Black English: A Linguistic and Social Analysis* (1972). His analysis is a paragon of exacting detail on the interaction of independent phonological and grammatical factors with social factors in the configuration of tense marking in African American Vernacular English. A less well-known but significant contribution to the study of English dialects is an unpublished paper Fasold wrote in 1969 on the vowel rotation in Detroit, Michigan, that Labov (1994: 178) acknowledges as the precursor of the widely recognized Northern Cities Vowel Shift.

In 1972, Fasold joined the faculty at Georgetown University to launch the first linguistics program in the United States with a specific PhD track in sociolinguistics. The program, funded initially by a grant from the National Science Foundation, brought together an anthropologist and psycholinguist with descriptive and applied sociolinguists to guide the first generation of PhD students concentrating in sociolinguistics. Fasold was involved in training sociolinguistic students at Georgetown for three decades, serving at various points as the Head of the Sociolinguistics Program, the Head of the Theoretical Linguistics Program, and the Department Chair.

While Fasold has maintained a continuing interest in the linguistic and social basis of systematic variability, this focus was complemented by a concern for the intersection of formal linguistics and sociolinguistics, particularly as they relate to the question of anaphora. He also has researched questions of language policy and planning, inspired by many of his international students and his lifelong concern for the application of sociolinguistic knowledge to fundamental social and educational problems. Among colleagues and students, he is known for his authentic humility and graciously affirming interactional style.

Ferguson, Charles A. (1921–98)

J. A. Fishman

One of America's leading linguists, with an unusually broad range of well-developed interests and a highly significant number of organizational accomplishments, Charles A. Ferguson was born on July 6, 1921, in Philadelphia, Pennsylvania, a city in which he also grew up and received his elementary, secondary, and higher education (University of Pennsylvania: AB 1942 (Philosophy), AM 1943, and PhD 1945 (Oriental Studies)). Having specialized in Arabic and Bengali, Ferguson was initially employed as a linguist for Near Eastern languages by the US Department of State, Washington DC,

from 1947 to 1955, and then joined Harvard University as a lecturer in linguistics and Arabic, remaining there until 1959.

In 1959, Ferguson became the founding director of the Center for Applied Linguistics, in Washington DC, a position which he maintained until 1966. Under Ferguson's leadership the Center developed from initially being under the auspices of the Modern Language Association of America into an independent institution, with a staff of approximately 100 and international stature in most of the areas of applied linguistics, a field which Ferguson and the Center firmly placed on the agenda of linguistics throughout the world.

While directing the Center, Ferguson also served as a member of the Social Science Research Council's Committee on Linguistics and Psychology (1959–61) and later became the chairman of the Council's Committee on Sociolinguistics (1964–70). In the course of half a dozen years Ferguson's leadership enabled the Committee to establish this new area of specialization as a recognized field of linguistic research and instruction, both in the USA and throughout much of the world, with journals, conferences, and research projects quickly being devoted to it. Ferguson's continued identification with sociolinguistics is evidenced by the very large number of articles and books which he has authored, coauthored, edited, and coedited in this field.

In 1967 Ferguson became Professor of Linguistics and the founding chairman of the linguistics program at Stanford University. Even in the early 2000s, linguistics at Stanford is characterized by a strong interest in many of Ferguson's areas of specialization, including not only those mentioned above but also child language, language universals, language and religion and, of course, all of the standard areas of general linguistics.

In addition to his own seminal publications, many of which have stimulated further research internationally (particularly his pioneering work on diglossia, language and religion, and on baby-talk), Ferguson has been honored by three collections of his selected papers (Dil 1971, Huebner 1996, Belknap

and Haeri 1997) and by a large two-volume *Festschrift* on the occasion of his 65th birthday (Fishman et al. 1986). The latter also contains a full bibliography of his published works, articles, books, and reviews, through to 1985.

Ferguson became Emeritus Professor of Linguistics in 1986 and continued to reside near the University, in Palo Alto, CA, together with his wife and colleague, Shirley Brice Heath, and their four children. He remained active in many of the areas of interest which he had pioneered and fostered throughout an exceptionally productive and stimulating career (sociolinguistics always continuing to be among them). Several years after his death commemorative books and entire journal issues continue to be dedicated to his memory (e.g., Fishman 2001, Hudson in press) as a gentle and provocative teacher, friend, provocative researcher, and theoretician. His own unassuming account and interpretation of his life and work are presented in an account published shortly before his death (1998).

Firth, J. R. (1890–1960)

F. R. Palmer

J. R. Firth was Professor and Head of the Department of General Linguistics in the Department of Phonetics and Linguistics in the School of Oriental and African Studies in the University of London from 1941–56, after having served as Senior Lecturer

and as Reader in that Department from 1938. The title of Professor of General Linguistics was conferred on him in 1944. He had previously been Professor of English in Lahore, India (1920–28) and from 1928–38 Senior Lecturer in the Department of

Phonetics at University College London, of which the renowned phonetician Daniel Jones was the head. During the Second World War has was in charge of short intensive training courses in Japanese, which both depended on, and influenced, his linguistic outlook. Firth's was the first and only Chair of Linguistics in Britain until 1960, but his influence is reflected in the rapid growth of the subject in the 1960s and the fact that seven members of his academic staff subsequently held chairs themselves, three of them in other universities.

Firth is probably best known for the work produced from 1948 until his death in 1960, but the work of the 'London School' includes the publications of his followers (almost all members of the department) from 1948 until the middle 1960s. His contribution can only be fully appreciated, however, in the light of his earlier works published in the years before the war. Most of his early publications, apart from two popular books *Speech* (1930) and *Tongues of Men* (1937; both reprinted in 1964), were mainly concerned with phonology, although 'The technique of semantics' ([1935] Firth 1957: 7–33) lays the foundation for his basic theory. It was in the field of phonology that he provided the greatest stimulation, with development of the theory known as 'prosodic analysis' that stemmed from his 'Sounds and prosodies' ([1948] Palmer 1970: 1–26). Most of the papers published by members of his department during the 1960s were on that topic.

A second theory with which Firth is closely associated is that of 'context of situation,' but this (and also, to some degree, prosodic analysis) are best understood in terms of his more general views on meaning. While his contemporary in the early years, Bloomfield, was suggesting that meaning was 'the weak point in language study' (Bloomfield 1935: 140), and later American linguists were to exclude it altogether, Firth was already developing his contextual theory of meaning, which is first clearly stated in 'The technique of semantics,' where ([1935] Firth 1957: 19) he speaks of meaning as 'situational relations in a context of situation' and says 'I propose to split up meaning or function into a series of component functions. Each function will be defined as the use of some language form or element in relation to some context. Meaning, that is to say, is to be regarded as a complex of contextual relations, and phonetics, grammar, lexicography, and semantics each handles its own components of the complex in its own appropriate context.'

Context of situation was 'a key concept' ([1950] Firth 1957: 181) of Firth's theory of meaning. He acknowledged that he had taken this expression from the anthropologist Malinowski, with whom he had worked in London, and whose views on meaning are best-known from his 'The problem of meaning in primitive languages,' which is a supplement to Ogden and Richards' (1923) *The Meaning of Meaning* as well as his own (1935) *Coral Gardens and Their Magic*. Malinowski's views on language derived from the difficulties he had experienced in attempting to translate the texts that he had collected, and his conclusion that they could only be understood if placed in the contexts in which they had been uttered. Written language, he suggested, was not the norm, but a far-fetched derivative function of language; language was not a 'mirror of reflected thought,' but a 'mode of action' (1923: 296). Firth felt, however, that Malinowski's context of situation was 'a bit of the social process which can be considered apart,' that it was 'an ordered series of events considered *in rebus*,' whereas his own context of situation was an abstraction, 'a schematic construct,' 'a group of related categories at a different level from grammatical categories, but rather of the same abstract nature.' The categories, he suggested, were (1):

(a) The relevant features of participants: persons, personalities.
   (i) The verbal action of the participants.   (1)
   (ii) The nonverbal action of the participants.
(b) The relevant objects.
(c) The effect of the verbal action.

Firth gives just one example, which represents 'a typical Cockney event' (2):

'Ahng gunna gi' wun fer Ber' '   (2)
(I'm going to get one for Bert.)

'What,' Firth asks, 'is the minimum number of participants? Three? Four? Where might it happen? In a pub? Where is Bert? Outside? Or playing darts? What are the relevant objects? "Obvious!" you say. So is the convenience of the schematic construct called "context of situation"' ([1950] Firth 1957: 182). In addition to these interior relations of the context, he later suggests that there should be reference to more general frameworks such as economic, religious, and other social structures, types of discourse (monologue, narrative, etc.), personal interchanges, and types of speech function such as drills and orders together with the social techniques of flattery, deception, etc. ([1957] Palmer 1968: 178).

In his last years Firth devoted much attention to translation (there are two papers in Palmer 1968). This was, in a way, appropriate, since his theoretical views had their origins in the problems that Malinowski had faced.

Anyone who reads Firth's work will inevitably be frustrated. Much of it is programmatic and sometimes unclear and apocryphal, and there is a great deal of repetition in successive papers. Yet it is, and was, stimulating, and offered a whole generation of scholars in the UK a new insight into language study,

as well as providing an alternative to the barren structuralism of his time. If some of it appears obvious today, it may be that he was ahead of his time.

Fishman, Joshua A. (1926–)
B. Spolsky

Joshua Fishman is acknowledged founder of the sociology of language, a spirited advocate of bilingual education in the USA, and a sympathetic friend of all groups who strive to maintain their ancestral languages.

Born on July 18, 1926, in Philadelphia, PA, he was educated there in public schools, at Olney High School, in elementary, secondary, and tertiary level Yiddish schools and courses, and, from 1944–48, at the University of Pennsylvania, where he earned BS and MS degrees. In the summer of 1948, he studied Yiddish, the language of his home and his Jewish education, at UCLA with Max Weinreich, the doyen of Yiddish linguistics, at the same time as did the latter's son Uriel Weinreich. His first scholarly article appeared, in *Yidishe shprakh*, in 1947; in 1949 he received a prize from the Yiddish Scientific Institute for an unpublished monograph on bilingualism (subsequently published in 1951). In 1951, he married Gella Schweid; they have three sons and Yiddish has remained the home language for them, their children, and grandchildren. From 1951–54, he was educational psychologist for the Jewish Education Committee of New York, at the same time studying social psychology at Columbia University, where he gained a PhD in 1953. From 1955–58, he directed research for the College Entrance Examination Board, combining this with teaching the sociology of language (disguised as social psychology) at City College (CUNY). In 1958, he became associate professor of human relations and psychology at the University of Pennsylvania, but 2 years later moved to Yeshiva University, New York, as professor of psychology and sociology; from 1960–66, he was also Dean of the Ferkauf Graduate School of Social Sciences and Humanities. In 1966, he became Distinguished University Research Professor of Social Sciences; from 1973–75, he served as academic vice president;

and, in 1988, became professor emeritus. He then began to divide the year between New York (where he has also become a Visiting Professor at New York University and at City University of New York Graduate Center, while maintaining his teaching connection with Ferkauf Graduate School of Psychology at Yeshiva University) and California (where he has become visiting Professor of Education and Linguistics at Stanford University). Four Festschriften were published in his honor by colleagues and former students on the occasion of his 65th birthday in 1991, each volume dealing with a different area of his specialization, and the Linguistic Institute of the Linguistic Society of America conducted a 4-day conference in his honor at that time.

Beginning with a number of publications on educational testing, he completed in 1964 his first major study of the sociology of language, *Language Loyalty in the United States*. A year later, *Yiddish in America* appeared. In 1968, he published three major books: *Bilingualism in the Barrio* (a pioneering study of a multilingual community), *Language Problems of Developing Nations* (the earliest major collection in language planning), and *Readings in the Sociology of Language* (a first attempt to define the new field). His prolific publication continued, amounting by now to over 900 items which have shaped and defined modern scholarly study of bilingualism and multilingualism, bilingual and minority education, the relation of language and thought, the sociology and the social history of Yiddish, language planning, language spread, language shift, language and nationalism, language and ethnicity, and (most recently) ethnic and national efforts to reverse language shift. Since its founding in 1973, he has edited the *International Journal of the Sociology of Language*. Some of his most influential works, authored or edited, are *Language and Nationalism*

(1972 [1989]), *Never Say Die!; A Thousand Years of Yiddish in Jewish Life and Letters* (1981), *Language and Ethnicity in Minority Perspective* (1989), *Yiddish: Turning to Life* (1991), *The Earliest Stage of Language Planning* (1993), *Post-Imperial English* (1995), *The Multilingual Apple: Languages in New York* (1997), and the *Handbook of Language and Ethnicity* (1999). Together with Gella Fishman he has also established the extensive five-generational 'Fishman Family Archives' at Stanford University Libraries, including his correspondence, course notes and outlines, lecture notes, manuscripts of his books, and papers and recordings/videos of his talks.

All his scholarly work with minority ethnic groups and with others engaged in the struggle to preserve their languages and traditions has been inspired by a deep and heartfelt compassion that has always sustained the markedly human tone in his most objective writings.

Foucault, Michel (1926–84)

J. C. Maher

Michel Foucault, philosopher, cultural historian, and sociologist whose critical theory involved influential observations on the role of language in society, was born in Poitiers, France in 1926. He held degrees in philosophy and psychology from the *Ecole Normale Supérieure* at the Sorbonne and the University of Paris. He also held a diploma in psychopathology and was a student of the Marxist scholar, Louis Althusser. After academic appointments in Sweden and Poland, he returned to France in 1960 as chairman of the Department of Philosophy at the University of Clermont-Ferrand and then as professor at the University of Paris-Vincennes (1968–70). He held the chair as Professor of the History of Systems of Ideas at the *Collège de France* until his death in 1984.

Foucault's inaugural lecture 'Discourse in Language' at the *Collège de France* in 1970 established his reputation in France as a leading ethnomethodologist of language (see *Ethnomethodology*). In this treatise, he examined the relation between truth and description in language arguing that if one wants to be heard in society it is not enough simply to 'speak' the truth rather one must be, in some sense, within the truth and embody its regime. The prohibitions surrounding speech inexorably reveal language's links with desire and power. In his investigation of mental illness, Foucault noted how, from the Middle Ages onward, a man was considered mad if his speech could not be said to form 'part of the common discourse of man.' The language of the mentally ill was considered either inadmissible in the authentification of acts or contracts or, alternatively, 'credited with strange powers of revealing some hidden truth, of predicting the future, of revealing... what the wise were unable to perceive' (1976: 216). By examining conventional explanations and understandings of madness (likewise, criminality or homosexuality) one can see how the boundaries of the normal are created as new forms of speech emerge.

Foucault's seminal studies on the religious, therapeutic, and judicial domains emphasized the presence of a 'fellowship of discourse' for each distinct social group. In what way does the dominant discourse of a powerful group, established in an 'institutional site' (e.g., hospital, prison), control those it marginalizes? Does not every speaker, in fact, unconsciously site an interlocutor or object of discourse within a power relation as the 'questioning subject,' the 'listening subject,' or the 'seeing subject'? The function of a fellowship is to maintain and reproduce discourse in order that it may circulate within its boundaries according to strict regulations. Foucault stressed that the meanings contained in discourse cannot be based upon an *a priori* system of signification as if the world is given to people simply to decipher. Discourse is, rather, a violence that people do to things.

Giles, Howard (1946–)

J. Bradac

Howard Giles is the founder of the relatively new field of language and social psychology, and congruously he was the founding editor of the *Journal of Language and Social Psychology*, established in 1982. He and W. P. Robinson convened the first International Conference on Language and Social Psychology at the University of Bristol in 1979, a seminal event that spawned several more international conferences (the most recent at Cardiff, Wales in 2000) that ultimately led to the formation of the International Association for Language and Social Psychology in 1997. Giles became President of this association in 2000. Essentially, Giles's research and that of others in the field has generally focused on phenomena residing at the intersection of language, mind, and society. Thus, some of his early work examined language attitudes, focusing on hearers' evaluative reactions to communicators using different accents or dialects, a difference that often reflects membership in different social groups. Communicators exhibiting these differences are often upgraded or downgraded along the dimensions of perceived status and solidarity.

Giles was born in Cardiff, Wales, on December 22, 1946. He obtained his PhD in social psychology from the University of Bristol in 1971 and was awarded a DSc in the same field from the same institution in 1996. In 1984, he became Professor of Social Psychology and in 1987 became Head of Psychology at the University of Bristol. In 1989, he moved to the University of California, Santa Barbara where he is currently Professor of Communication and Assistant Dean of Undergraduate Studies, with appointments also in Psychology and Linguistics.

Giles may be best known for his communication accommodation theory (CAT), the roots of which can be seen in his doctoral dissertation. This theory, which was initially labeled speech accommodation theory (see *Speech Accommodation*), has evolved over the years and has stimulated a great deal of research in several fields, including linguistics, sociolinguistics, communication, and psychology. Essentially, the theory is concerned with antecedents for, and consequences of, one person's convergence to or divergence from the language style of a partner in interpersonal communication. Style refers to consistent individual or group variation in any phonological, lexical, or syntactic feature of language. Communicators may converge to the style of others in order to attain social approval or they may diverge to achieve subjective group distinctiveness. Convergence tends to produce favorable attitudes toward the converger in the mind of the person converged to, whereas divergence tends to produce unfavorable attitudes, although there are many mediating variables that can upset this general prediction. Accommodation processes have been shown to operate in the domain of nonverbal communication as well. Additionally, Giles is well known for his theoretical and research work in ethnolinguistic vitality, language and ageing, patronizing speech, and hate speech.

Giles is a fellow of six learned societies, including the British Psychological Society, the American Psychological Society, and the International Communication Association. He was the British Psychological Society's Spearman Medalist in 1978 and was recipient of that society's President's Award in 1989. In 1993, he received the inaugural Outstanding Scholar Award from the Language and Social Interaction Division of the International Communication Association.

Gilliéron, Jules (1854–1926)
T. Hill

Jules Louis Gilliéron, one of dialectology's most influential figures, was born at Neuveville, Neuchâtel, Switzerland, the son of a language teacher and geologist, who introduced him to field research and mapping. He qualified in Romance philology at Neuchâtel and Basel, then continued his studies with Gaston Paris at the *École normale des hautes etudes*, Paris, where he was to pass his entire professional life: maintaining himself in the earlier years as a college teacher of German. Having received his diploma for a monograph on the dialect of Vionnaz, in 1883 he became the first professor of 'Gallo-Roman dialectology' (i.e., the French dialects of France and the adjoining countries).

Gilliéron and his pupil Rousselot founded the *Revue des patois galloromans* (1887–93), for the publication of dialect monographs. In 1888 Gaston Paris called for a dialect atlas, and with his help regarding finance and publication Gilliéron undertook the project. He decided that a reliable, uniform body of data (notably lacking in the monographs) could be achieved only by means of a standard questionnaire, operated by a single nonacademic fieldworker trained by himself. For this he discovered the remarkable amateur Edmond Edmont (1849–1926), grocer and leading citizen of Saint Pol-sur-Ternoise, by Dunkirk. Edmont had achieved recognition for his local folklore collections, and in 1887 Gilliéron's *Revue* published his *Lexique saint-poloise*, a glossary complied with unusual phonetic accuracy. After training in transcription, the middle-aged enthusiast was dispatched on a three-year cycle tour of France (1897–1901), to collect data from a single informant in each of over 600 places; in 1911, aged 62, he repeated this performance for the atlas of Corsica.

The questionnaire was a list of words and phrases for translation into the dialect, yielding about 2000 singleword items of phonological, lexical, or grammatical interest: each item to appear in the atlas as a separate map. The object was to establish not merely the forms of each dialect, but also how it was surviving vis-à-vis the standard language, and the speaker's attitude to it. Accordingly, only the speaker's first, unprompted response was to be noted, with

notes of interest on hesitations, etc. The maps were edited jointly by Gilliéron and Edmont, and published between 1902 and 1910 as the *Atlas linguistique de la France* (ALF).

From 1905 on, in lectures and interpretive monographs, Gilliéron developed his distinctive 'biological' view of language. Initially the ALF attached less interest at home than in, e.g., Germany, and some of Gilliéron's best known monographs were first published privately in his native village. However, his courses attracted universal scholarly attention in due course, and his writings have become classics of methodology, widely quoted in textbooks of linguistics. Gilliéron's concern was chiefly with 'intralinguistic dialectology,' i.e., the use of the geographical data to elucidate the structure and development of the language. It was naturally affected by the highly specific nature of the French language and its territory.

Gilliéron's approach has been criticized for overinterpretation of exclusively French data, while ignoring relevant facts from the wider Romance field. It is also observed that in his word histories he tacitly admits the operation of sound laws, while denying their validity in principle. Nevertheless, his achievement is probably the greatest single contribution to dialectology, and has provided the model for surveys throughout the world: in particular in the Romance, Slavonic, and Scandinavian countries, the USA, and England.

Goffman, Erving (1922–82)
R. L. Schmitt

Erving Goffman, a Jewish Canadian, spent three decades studying face-to-face interaction through naturalistic observation, completing 11 radically influential books and significant articles and chapters. Goffman's essays, his preferred style of presentation, influenced sociologists, anthropologists, linguists, and psychiatrists. He was not uniformly respected and his status was even varied within sociology, although his contributions to microsociology, deviance, and medical sociology were unmistakable.

Goffman's signature was controversy. His methods, theoretical persuasion, political stance, the import of his ideas, and, curiously, his personal lifestyle were religiously criticized. Attention to Goffman since his demise, however, has clarified the cornerstone of his career as *microsociological constraint* and marked much of the criticism as wrong-headed. Goffman is sometimes inappropriately described as a 'symbolic interactionist.' Symbolic interactionism emphasizes the self as a being constantly interpreting events. While for Goffman (1959: 252), the self itself was an imputation made by an audience. Goffman's intellectual roots are also often traced to the French sociologist, Emile Durkheim, but Durkheim was interested only in the constraint that was generated by the broad macrostructures within society. Goffman (1983) concluded in his Presidential Address to the American Sociological Association that the constraint that had uniquely concerned him throughout his lifetime was anchored within the 'interaction order,' i.e., a face-to-face encounter.

The dynamics of microsociological constraint was the agenda from Goffman's keynoting book, *The Presentation of Self in Everyday Life* (1959), through *Relations in Public* (1971). The dramaturgical perspective elaborated in these essays revealed how the sacredness of self morally constrained participants to ritually maintain interaction primarily through rules of courtesy and irrelevance. Rules of courtesy morally oblige persons to involve themselves in interaction and to protect the presented selves of others. Rules of irrelevance enable interactants to disattend hierarchies that would mediate against the fundamental equality demanded by the interaction order. The complexity of maintaining equality with those having deeply discredited identities was the core of Goffman's *Asylums* (1961) and *Stigma* (1963). Many concepts which are now synonymous with Goffman were developed in his 1959–1971 essays, including 'dramaturgy,' 'impression management,' 'face,' 'focused and unfocused interaction,' 'encounter,' 'strategic interaction,' 'expressions given,' 'expressions given off,' 'backstage,' 'frontstage,' 'remedial work,' 'role distance,' 'identity documents,' 'total institutions,' 'spoiled identities,' and 'secondary adjustments.'

Goffman turned to frames in his most systematic book, *Frame Analysis* (1974). The frame addresses the question, 'What is it that is going on here?' Primary frames are organizing definitions of the situation that can be understood without reference to other definitions, for example, *two lovers kiss*. Goffman's frame, however, differs from the symbolic interactionist's 'definition of the situation' because frames are given in a situation. They have a pre-existence, are always shared, usually unambiguous, and are equally 'real.'

Transformation/lamination/layered activity is the distinctive contribution of *Frame Analysis*. Goffman underscores the relational quality of reality by showing how multiple realities are interrelated. Transformations are definitions that systematically build on other definitions and encompass keys (pretend kiss between actors) and fabrications (con-man kisses widow). Goffman details various types of primary frames, keys, and fabrications and explains how primary frames and transformations are anchored in the everyday world. Paradoxically, laminations have contributed to the analysis of emergent, as well as existing, frames, including fantasy role-playing games (Fine 1983) and frame debates (Schmitt 1985).

Linguistics, ostensibly, captured Goffman's interest in *Forms of Talk*, but, for Goffman (1981: 71), 'conversation [only] constitutes an encounter of a special kind.' Goffman's views of dramaturgy and frame are suggested in his analysis of 'response cries' (whoops); the lecture; and radio talk. The import of his final book is its sociolinguistic corrective for linguistics, particularly 'conversational analysis,' a specialized branch of ethnomethodology: talk, not language or grammar, protects selves. Talk may have communicative effects but not be dialogic.

Conversation cannot be studied exclusively as oral communication or apart from context. The speaker–hearer dichotomy is inadequate because speakers switch frames. Their 'footing' shifts in various ways as they change their stance to what they say. A 'move' or unitary action, not the sentence, should be the unit of observation.

Goffman (1983) recommended that the interaction order be studied in relation to other social structures, but the memories, emotions, and meanings that concern symbolic interactionists were never mentioned. Goffman (1967: 3) remained steadfast in studying, 'Not ... men and their moments. Rather moments and their men.' Interaction orders, however, will lurk as sterile and unfulfilled enclosures until the processes that weave them together in the lives of selves, relationships, and groups are identified.

Görlach, Manfred (1937–)

E. W. Schneider

Manfred Görlach is one of the founding fathers of 'English as a world language' as a scholarly sub-discipline, closely related to sociolinguistics. He has built a publication infrastructure for this field, stimulated much relevant research, and published widely himself (more than two dozen books, dozens of articles, and hundreds of reviews), always emphasizing sociolinguistically relevant aspects.

Born on July 12, 1937, in Berlin, in the early 1960s he was forced to interrupt his studies in this city when, having helped friends to leave the communist state after the building of the Berlin Wall, he was sentenced to a three-year confinement in an East German penitentiary for refugee smuggling. After-wards, he taught at the University of Heidelberg, where he received his PhD in 1970 for an analysis of Middle English saints' legends. In 1984 he moved to Cologne to accept a Chair of English Linguistics which he held until his retirement.

Görlach was trained as a language historian and has continued to work in this field throughout his career. He soon became well known for two books, originally published in German—a language history adopting structuralist principles of description (1974; English translation, 1997) and an *Introduction to Early Modern English* (1978; English translation, 1991). Like two later books similar in orientation and structure (*English in Nineteenth-Century England* 1999, *Eighteenth-Century English* 2001), these volumes not only provide systematic coverage of the features of the English language of those periods, emphasizing the sociolinguistic usage conditions of dialects and sociolects and their historical and cultural background; they also illustrate this material with a rich array of sample texts which make up half of each book, texts cross-referenced to the general chapters, and thus illustrating the importance which the author places upon readers' immediate exposure to authentic texts.

Late in the 1970s Görlach became aware of the growing importance but limited scholarly coverage of varieties of English as a world language, and embarked on this topic. Along with Richard Bailey he co-edited *English as a World Language* (1982), the first classic handbook of this discipline. In 1980 he founded *English World-Wide*, the earliest international scholarly journal on this subject, and edited it until 1997. He also founded and edited a companion book series, *Varieties of English around the World*, and inspired a great many studies published there. His continuing emphasis on familiarity with source texts is reflected in a *Text Series* division, which

publishes systematically compiled printed and tape-recorded text samples. He also authored a large number of articles on almost all national forms of English, typically characterized by an immense breadth of knowledge and sytematicity of description and comparison; these are put together in several collective volumes (*Englishes*, 1991, *More Englishes* 1995, *Even More Englishes* 1998, *Still More Englishes* 2002). Again, his work in this area has tended to be marked by an emphasis upon the textual basis and empirical documentation, as well as upon the historical and sociocultural factors that have shaped the sociolinguistic determinants of varieties of English around the globe.

Gramsci, Antonio (1891–1937)

N. Helsloot

As a Marxist politician, Gramsci not only attached practical conclusions to linguistic theory, but also contributed to a political interpretation of linguistics itself.

He was born on the Italian island of Sardinia, where he grew up in poverty. He suffered from ill health. Though he had to work during some of his school years, he won a modest scholarship which enabled him to study philology at the University of Turin. Here he was initiated in the 'neolinguistic' school of Matteo Bartoli. The social turbulence of industrial Turin involved him in politics. He started working as a journalist and editor for the weekly paper of the Socialist Party, and became a founder and leader of the Italian Communist Party. As a member of parliament, he didn't think it appropriate to escape the increasing fascist pressure. In 1926 he was imprisoned in spite of his parliamentary inviolability. Because of the lack of medical care he became ever more ill and died in prison, some days after his official release.

As a student Gramsci furnished data for Bartoli's studies of the Sardinian dialect. Influenced by theories of linguistic radiation, he increasingly stressed the emancipatory qualities of dialects. The historical dispersion of language variants (and the implied world views) is no matter of personal choice, but Gramsci encouraged intellectuals (public speakers and writers) to further historical necessity by 'organically' taking side with rising social movements instead of sticking to established values. Thus, he criticized linguistic isolationism, like that of the Latin-speaking catholic clergy and of Mandarin-speaking Chinese leaders. He also opposed the cosmopolitanism of the Esperanto movement as not fitting in with the needs of the masses; likewise, he blamed the dominance of the Italian of Florence on the cultural hegemony of an outdated class. Gramsci argued strongly for a change, focusing on cooperation between northern industrialized Italy and the underdeveloped rural south (including Sardinia). He denied any grammaticality, correctness, or truth in language apart from the way in which it is alive in practices that are socially real and politically open. By cooperating, isolated minority languages may gain popular adherence and prestige. Linguistics should stimulate such change.

Most of Gramsci's work was written in prison and smuggled out. Editions of selected parts of his prison notebooks appeared in the years after the Second World War, when Gramsci became one of the main sources of inspiration for Italian communism. A complete edition, showing his concern with the problem of linguistic unity and the diffusion of culture, did not appear until 1975. Outside of Italy, Gramsci's reputation spread in the course of the next decade. Because of his defense of differences against enforced unity, his view of language and culture matched that of postmodern thinkers like Althusser and Foucault, and stimulated a political elaboration of anti-foundationalist theories of language.

Grierson, Sir George Abraham (1851–1941)

J. C. Wright

Sir George Abraham Grierson ICS OM KCIE FBA was the originator and compiler of the monumental *Linguistic Survey of India* (Grierson 1903–27). Completed in his 77th year, the *Survey* had been proposed to him as a work for life by Professor Robert Atkinson who, at Trinity College, Dublin, first developed in Grierson an interest in linguistics.

Grierson was born on January 7, 1851 at Glanageary, Co. Dublin. For 23 years, while an active member of the Indian Civil Service, he produced a vast series of publications bearing on the languages and orally transmitted literatures of North India, notably the Bihar dialects, the Hindi of Oudh and Braj, Kashmiri, and Gypsy Romani. His exemplary *Bihar Peasant Life* (Grierson 1885) constitutes a linguistic–geographical study of vocabulary in which the implements and procedures of an agricultural province are described and illustrated. He compiled the first extensive bio-bibliography of literature in the modern Indo-Aryan vernaculars, and conspectus accounts of their distribution and linguistic affinities.

Grierson's *Linguistic Survey of India* (1903–27) was presented to the government as intended, to enable British administrators to communicate directly with the local populace, but it was devised rather with a view to revealing the richness of modern India's vernacular cultures to a West hitherto mesmerized by India's past. In 1898, after protracted negotiations, Grierson was permitted to reside and work in Camberley, Surrey, where he was assisted for a time by the Norwegian Sten Konow who contributed much of the material relating to non-Indo-Aryan languages.

In its necessarily curtailed form, the *Survey* ensured that for every patois that could be identified, one specimen of original narrative and the translation of one standard text would be collected, along with a list of words and test sentences. The provinces of Madras and Burma, and the states of Hyderabad and Mysore declined to participate. As a result, only 179 of the 188 languages currently censused could be covered, together with 544 identified 'dialects.' Some 250 gramophone records illustrate forms of speech circa 1920. The inherent problems would have been insurmountable, but for the fact that so well-qualified a philologist and linguist was able, as a civil servant, to divert to the task some of the administrative resources of the Imperial Government and its allies. For all its inevitable faults in detail, traceable usually to the effect of political geography in predetermining linguistic groupings, Grierson's classification remains adequate for practical purposes (notably the subsequent Censuses of India) and a reference point for all research involving the languages of the Subcontinent—Mon-Khmer, Tai, Tibeto-Burman, Munda, Dravidian, and Iranian, as well as Indo-Aryan. Materials for a subsequent Ethnographical and Linguistic Survey of Burma, compiled by L. F. Taylor, were lost as a consequence of the invasion of Burma.

After completing the *Survey* in 1927, Grierson went on publishing specimens of Indo-Aryan literatures well into his eighties. He died on March 9, 1941.

Gumperz, John J. (1922–)

N. Berenz

With more than 100 published books and articles, John J. Gumperz has been a major figure in the field of sociolinguistics for four decades. The introductory chapter to *Linguistic Diversity in South Asia* has been hailed as 'the first concise statement of sociolinguistic problems ... unequaled in its grasp of the broader issues' (Dil 1971). *The Ethnography of Communication* and *Directions in Sociolinguistics* are foundational works. *Language in Social Groups* is a classic for its insights into how social groups retain their identities in complex societies.

As the founder of Interactional Sociolinguistics (see *Interactional Sociolinguistic Research Methods*), Gumperz draws on a wide variety of analytic tools— among these, implicature, speech acts, frames, network, ethnicity, and habitus—to link the macrosociological to the microconversational. His key concept, contextualization, is clearly set out in *Discourse Strategies*, which is widely used as a textbook. His chapter in *Rethinking Linguistic Relativity* reframes the Whorfian notion in terms of conversational inferencing.

Gumperz's work in institutional settings, particularly those involved in employment and education, continues to produce crucial insights into communicative practices and interpretive processes. He calls attention to minorization, the often unintentional process through which the life chances of members of particular social groups are diminished as a result of variation in cultural presuppositions and rhetorical styles. He shows that such variation contributes to communicative breakdown and may lead to pejorative stereotyping. His findings also contribute to our understanding of the process of linguistic change.

Gumperz's interest in cross-cultural communication and his concern with social justice may have its roots in his early life. As a teenager in the years leading up to World War II, Gumperz emigrated with his family from Germany to the United States. After earning a PhD (1954) at the University of Michigan, Ann Arbor, Gumperz went to India on a Cornell post-doctoral fellowship. There he carried out sociolinguistic studies on language contact and on the role of language in social stratification. Fieldwork in Norway in the 1960s broadened his interest in dialect maintenance and loss, as well as the link between language and social identity.

Gumperz recognized early on the importance of a comparative perspective, as demonstrated by his work on bilingualism and linguistic diffusion. In the 1970s Gumperz focused on the analysis of sociocultural symbolism in bilingual and ethnically mixed groups in India, Austria, the UK, and the United States. From the 1980s to the present, he established and is further developing Interactional Sociolinguistics as both a theory and a research methodology.

During his long teaching career at University of California at Berkeley (where he is now Professor Emeritus) and as a visitor at other American and European universities, Gumperz's courses and seminars introduced Interactional Sociolinguistics to scores of sociolinguists and linguistic anthropologists. He has been a Fellow of the National Science Foundation, the Guggenheim Foundation, the American Academy of Arts and Sciences, and the Max Planck Project Group in Cognitive Anthropology, among other honors. Gumperz remains actively engaged in research from which emerge new insights into the communicative complexities of our multilingual/multicultural world.

Hall, Robert A. Jr (1911–97)
M. Danesi

Hall contributed substantially and substantively to several areas of scientific language study, including the reconstruction of Proto-Romance (see Hall 1950, 1976, 1984), the study of pidgins and creoles (see Hall 1966) and to an appreciation of the life and thought of Leonard Bloomfield (Hall 1987a, 1990). He was also known for his caustic critique of the generative paradigm in linguistics (see Hall 1987b). In addition, Hall produced several widely read textbooks from 1948–68 (Hall 1948, 1960, 1964, 1968) with the aim of explaining the main concepts and techniques of American structuralist linguistics to a broad, general audience. He also wrote extensively on the Romance languages (especially Italian), on literary criticism, and on topics related to the teaching of foreign languages. (A bibliography of his published works 1936–87 can be found in Danesi 1987.)

Hall was born on April 4, 1911 in Raleigh, North Carolina. He graduated with a BA from Princeton University in 1931, later receiving the AM from the University of Chicago and the degree of Doctor of Letters from the University of Rome in 1934. At Princeton he majored in French and German literature. He was introduced to linguistics by Harry Hoijer while in graduate school at Chicago. Hoijer's lectures, which were based on Sapir's 1921 text *Language* (see *Sapir, Edward*), convinced Hall to change his program of study from literary criticism to linguistics. While at Chicago he also took a course on the history of the French language with T. Atkinson Jenkins. Jenkins's emphasis on the importance of *etymology* fostered in Hall an abiding interest in historical linguistics, and especially, in the reconstruction of proto-languages. This interest led him in the early 1950s to undertake extensive research on the reconstruction of Proto-Romance.

From 1937 to 1946 he held teaching positions at the University of Puerto Rico, Princeton University, and Brown University. From 1946 on he taught linguistics and Italian at Cornell University where he remained until his retirement in 1977. At Cornell he developed a close personal and professional relationship with Charles F. Hockett.

During World War II he was in charge of the US Army Italian courses at Yale University and the US Navy Pidgin English courses at Columbia University.

As a summer lecturer at the Linguistic Institutes of Indiana University and the University of Michigan he worked closely with neo-Bloomfieldian linguists. It was at the 1938 Linguistic Institute that he became intrigued by Leonard Bloomfield's ideas on applying linguistics to language teaching, although he argued with Bloomfield over the desirability of teaching grammar to school-age children (see Danesi 1987: 55). At various times in his career, Hall also held executive positions in the Linguistic Society of America, the American Association of Teachers of Italian, the Wodehouse Society, and the Linguistic Association of Canada and the United States.

Trained within the paradigm of American structuralism, Hall was always one of its main defenders, frequently emphasizing the need to be wary of turning linguistics into a theory-dominated discipline. Like other Bloomfieldians, Hall always argued that any theory should be based on the painstaking collection and analysis of data which reflect the individual and social embodiments of language. His writing style is always lucid and to the point. In his more popular writings his prose is often terse and witty. At times, his deeply rooted joviality rises to the surface in amusing ways, as when he assumed the pseudonym 'Berto Sala' for two of this works of fiction (Hall 1959, 1981). This is the Italian equivalent of his name (*Berto* = Robert, *Sala* = Hall). His overall view of the scientific linguistics enterprise can perhaps best be summed up in his own words, uttered near the start of his long and illustrious career (1948: 249): 'The contribution of linguistics is simply a part of the effort of all science in modern democratic society to find out the truth and to act upon it.' Hall died on December 2, 1997.

Halliday, Michael Alexander Kirkwood (1925–)

J. Fine

Halliday has developed systemic function linguistic theory and its application to education at all levels.

Halliday received his BA from London University in Chinese language and literature and his PhD from Cambridge University in 1955 (published as *The Language of the Chinese 'Secret History of the Mongols'*). Halliday held professorships at University College London, 1965–70, University of Illinois, Chicago circle, 1973–75, and at University of Sydney, 1976 to his retirement in 1987. He has been visiting professor at Yale, Brown, University of California (Irvine), Nairobi, National University of Singapore, and Fellow of the Center for Advanced Studies in the Behavioral Sciences, Stanford, California.

Systemic functional linguistic theory that Halliday developed with others is concerned with the operation of texts in their contexts. Language is seen as sets of meaning resources that are selected for use in particular social contexts. Field, mode, and tenor are the variables that are at stake in contexts. Meanings at various levels of abstraction (e.g., ideology, genre, register) are studied paradigmatically to present the meaning contrasts that speakers draw from. The meaning contrasts are then worded (technically, 'realized') by the lexis and grammar of the language. The linguistic choices are grouped into the ideational, interpersonal, and textual metafunctions.

Halliday has applied functional systemic theory to education from early language learning to university education. He has studied the intonation, vocabulary, cohesion, and grammar in first and second language teaching and learning. In these applications the emphasis is on the speaker's control over text types, the ways texts are constructed and the functions of language in social contexts. Halliday's approach to language and education has had a substantial influence on the Australian education system. His work on grammar, cohesion, and intonation is widely used in research on education, language learning, and pathology.

He is an honorary member of the Linguistic Society of America, and holds honorary doctorates from the Universities of Nancy and Birmingham.

Haugen, Einar (1906–94)

N. Hasselmo

Einar Haugen was a leader in the development of the field of sociolinguistics during the second half of the twentieth century, while also making major contributions to the debate on linguistic structuralism and to

language pedagogy, Scandinavian philology and dialectology, and Scandinavian–American cultural relations.

Haugen was born on April 19, 1906 to John and Kristine Haugen, Norwegian immigrants to the USA, and learned English as his second language. After finishing his BA at St. Olaf College in Northfield, Minnesota, in 1928, he studied under George T. Flom at Illinois, receiving his PhD in 1931 with a dissertation on Ivar Aasen's New Norwegian language. From 1931 to 1964 he served as professor of Scandinavian languages at Wisconsin, becoming Victor S. Thomas Professor of Scandinavian and Linguistics at Harvard in 1964. His many scholarly leadership positions include the presidencies of the Society for the Advancement of Scandinavian Study (1938), the Linguistic Society of America (1950), the Ninth International Congress of Linguists (1962), and the American Dialect Society (1965). Haugen was a member of the American Academy of Arts and Sciences and several Scandinavian academies. He was the recipient of fellowships from the Guggenheim Foundation, the NEH, and the Center for Advanced Study in the Behavioral Sciences, and served in a visiting or advisory capacity in Scandinavia and Japan. He was honored by the governments of Iceland, Norway, and Sweden, and held honorary degrees from St. Olaf College and the Universities of Iceland, Michigan, and Oslo.

Haugen participated actively in the debate on the nature of linguistic structuralism from the late 1930s, arguing for linguistic realism and serving as a link between European and American structuralism. With *The Norwegian Language in America* (1953) and *Bilingualism in the Americas* (1956), Haugen—with Uriel Weinreich—created a new theoretical and methodological framework for the study of bilingualism and language contact. He helped lay a new foundation for the study of language in its socioeconomic setting, and became one of the founders of the fields of sociolinguistics and contrastive linguistics. With his analysis of the problems of, and solutions to, linguistic subjugation in *Language Conflict and Language Planning* (1966), Haugen reinvigorated and gave respectability to the modern field of language planning and provided a paradigm for the now flourishing study of language policy and practice in developing countries. Linguistics owes to Haugen such concepts as 'bilingual description'— which became contrastive linguistics—'diaphone' and 'diamorph,' 'semi-communication,' 'schizoglossia,' and 'ecology of language.' In addition to his sociolinguistic work on the Scandinavian languages and specialized studies on Old Norse phonology and Norwegian dialectology, Haugen made major contributions to Scandinavian language pedagogy: several textbooks in Norwegian, a *Norwegian–English Dictionary* (1965), and *The Scandinavian Languages* (1976). Haugen also wrote on Scandinavian literature and Scandinavian–American cultural relations and served as a translator from the Norwegian.

Heath, Shirley Brice

C. B. Cazden

Shirley Brice Heath's *Ways with Words* (1983, 11th printing 1996 with postepilogue) has become an international classic. An example of research in educational anthropology, ethnography of communication, and sociolinguistics, it is arguably the most widely cited study of children's language use in and out of school. Reading of Heath's long engagement with three communities in a southeastern area of the United States—poor white, poor black, and middle-class white and black—as they sent their children to the then newly integrated public schools, one wonders how one person could become a trusted adult with multiple participant and research roles in all three groups.

Heath grew up in rural Virginia. Her grandmother ran the store in an otherwise all-black community. So from the beginning she became aware of herself as a minority, an 'other.' Close relationships with those different from herself continued through her work in the early years of the civil rights movement in

Mississippi and teaching migrant children in California. Along the way, she studied in six colleges toward BA and MA degrees, learning at different times and places: how to teach special education, reading, and English as a Second Language; and English, linguistics, Spanish, and sociology. When Heath applied for a doctorate, she was reminded again of her own marginalized identity when she was admonished to replace her southern accent with 'general American' pronunciation.

Heath received her doctorate in cultural anthropology and linguistics from Columbia University in 1970, and taught first at Winthrop College, South Carolina, where she started the research that became *Ways with Words*. After early reports of that research became known, Heath moved to the University of Pennsylvania Graduate School of Education in 1977, and then to Stanford University in 1980, where she is a professor of English and Linguistics and, by courtesy, Anthropology and Education.

On paper, these biographical details may read as a fragmented education. But the total helps to explain the range of Heath's scholarship and professional work. *Telling Tongues* (1972) is a historical study of language policy in Mexico. *The Braid of Literature* (1992) is a study of two children's literary development, co-authored with the children's mother, with extensive notes on connections to literary theory. *Language in the USA* (1981), co-edited with her sociolinguist husband Charles Ferguson (see *Ferguson, Charles A.*), is a panoramic view of a more multilingual US than its usual public image. The co-edited *Handbook for Literacy Educators* (1997) attests to her commitment to understanding student learning and the importance of all the communicative arts in education. *Identity and Inner-City Youth* (1993) is a co-edited collection that can be read as an introduction to her next book: a 10-year ethnographic and sociolinguistic study of the language and learning of adolescents in out-of-school youth organizations and enterprises around the US. She has also written more than 100 articles and chapters.

For these achievements, Heath has received many honors, including being named a MacArthur Foundation Fellow and a member of the National Academy of Education; and awarded the George and Louise Spindler Award for Scholarly Contributions to Educational Anthropology, the David Russell Research Award of the National Council of Teachers of English, and the Grawemeyer Award in Education.

Hesseling, Dirk Christiaan (1859–1941)

G. G. Gilbert

Dirk Hesseling was born in Amsterdam and died in Wassenaar. From 'a well-to-do merchant's family' (Muysken and Meijer 1979: vii), he enjoyed a first-rate education, with studies of Greek and Latin at Leiden, trips to the Mediterranean, and the study of Modern Greek in Paris. His doctoral thesis at Leiden was *On the Use of Wreaths among the Greeks: Selected Chapters* (in Latin). At the University of Leiden, he became '*privaatdocent*' in 1893, and was appointed to the chair of Byzantine and Modern Greek in 1907, a post which he held until 1929. His 'knowledge of languages was encyclopedic; we find references to all stages of English, French, Latin, Greek, Hebrew, Russian, German, Spanish, Portuguese, and several other languages. It is unclear, however, whether he considered himself more of a Greek scholar, or more of a creole scholar' (Muysken and Meijer 1979: viii).

Hesseling was a highly original scholar, who, throughout most of his professional life, pursued an unlikely combination of classical languages and creole languages. When one realizes, however, that his focus on Greek and Latin was on their koineization (see *Koinés*) and dispersal in space and time, it is

879

not hard to follow his reasoning in seeing the same principles operating in the diaspora of the European colonial languages of the last 500 years, especially with regard to Dutch and English, and to Portuguese, French, and Spanish. He was a contemporary of Hugo Schuchardt (see *Schuchardt, Hugo*), and it is clear that each scholar had much to tell the other. In preparing his early published work on Afrikaans and Negerhollands, for example, Hesseling shows that he was well aware of his German colleague's studies of the Romance- and English-based creoles, publications dating from the 1880s. More than 20 years later, after Schuchardt's interests had turned primarily to other areas of linguistics (Basque and Georgian, for instance), it was Hesseling who encouraged him to publish Schumann's eighteenth-century manuscript dictionary of Saramaccan, which had been sent to Schuchardt from South America many years previously. Schuchardt, then over 70, took the occasion to express his well-considered views on the origin and development of the Saramaccan language, and on creolistics generally. Prior to John Reinecke's 1937 Yale doctoral dissertation (see *Reinecke, John E.*), this was the closest thing the world had seen to a textbook on the subject (Gilbert 1980: 90). Despite the complications of the onset of World War I (in which Austria and the Netherlands found themselves on opposing sides), Hesseling was successful in seeing the work through its publication in 1914 in Amsterdam. (Hesseling's correspondence with Schuchardt on the publication of Schumann's dictionary, and on other matters, is preserved in Graz.) Hesseling's 1899 and 1905 books, on Afrikaans and Negerhollands, were very much products of the spirit prevalent at the *fin de siècle*. As Muysken and Meijer put it:

> In a sense, Hesseling was very much between two worlds, 'at the turning point of two centuries,' to use the phrase coined by the Dutch historian Jan Romein. He was a classical scholar who much preferred spoken modern Greek and Italian to their classical ancestors. Yet he was a philologist who never got around to doing fieldwork at a time when Boas (see *Boas, Franz*) and his students were already studying the native languages of North America actively (1979: xix).

Hesseling regarded Afrikaans as a 'semi-creole,' to use the term evidently coined by Reinecke in 1937 or 1938. 'African [sic] was originally a "semi-creole patois" as you say, but the process has been brought to a stand' (letter from Hesseling to Reinecke, dated December 22, 1938, the original preserved in Honolulu, with a copy in Hesseling's hand, in Leiden). He emphasized the (until then) surprisingly strong influence, unwelcome in many white South African circles, of Malayo–Portuguese, as it had been described by Schuchardt, in the formation of Afrikaans. He was also inclined to accept broadly universalist and developmental explanations of the similarities that had been observed worldwide in the evolution of creole languages—essentially the point of view expressed in the 1880s by Coelho. Accordingly, he would have little to do with the extreme substratal position (retention of L1 structure in the lexical clothing of the European L2, in both pidgins and creoles) espoused by the French anthropologist, Lucien Adam. Although his work formed an important link in the chain of scholarship, stretching from Coelho through Valkhoff and Whinnom, that clarified the role of Portuguese in the development of modern creoles of whatever lexical base, Hesseling was clearly not the author of the monogenesis theory, namely that Portuguese Creole was the ur-creole from which most others developed (Muysken and Meijer 1979: vxi–xvii). (Most scholars agree in giving Keith Whinnom the credit for that proposal.) The fact that Hesseling wrote largely in Dutch has doubtless impeded access to his writings—most of which remain unavailable in any other language. Notwithstanding, his thorough and interesting comparisons of creole languages, and his suggestions for future research, reserve for him a distinguished place in twentieth-century creolistics.

Hill, Jane (1939–)
V. Santiago-Irizarry

Jane Hassler Hill was born in Berkeley, California, on October 27, 1939. Her parents were on the faculty at UCLA. Hill attended public schools in Los Angeles.

Her roots in academia led her to a scholarly career from the outset. She graduated in 1960 with a bachelor's degree from Berkeley and the Departmental Award in anthropology. During this period of her training, she took classes with Clifford Geertz, Robert Murphy, John Rowe, Sherwood Washburn, and Seth Leacock, among other outstanding anthropologists then at Berkeley. Hill originally wanted to be an archaeologist, but the Berkeley Field School did not admit women at the time—ostensibly to avoid digging up extra latrines. David French, who had mentored her at Reed, and William Shipley at Berkeley were the first to inculcate in her an interest in the anthropology of language.

By the time she entered graduate school at UCLA, Hill had already spent two summers in Peru, participating in an ethnopharmacological expedition led by her mother and by Dermot Taylor of the UCLA Medical School. This first taste of Latin American fieldwork further shaped her career trajectory.

While doing her master's degree in linguistics at UCLA, she met her husband and professional collaborator, Kenneth C. Hill, whom she married in August of 1961; they had three children.

Hill wrote her dissertation on Cupeño grammar, a Uto-Aztecan language of southern California, and defended it in 1966. Because of an interesting coincidence, her work with a small community of the language's last indigenous speakers became her first incursion into issues of language 'death,' a topic regarding which her expertise is recognized and highly regarded. Shortly after Hill wrote her dissertation, the then-archivist of the Lowie Museum at Berkeley, Dale Valory, found a batch of field notes on Cupeño collected by one of Kroeber's students, Paul-Louis Faye. With funding from the American Philosophical Society, Hill worked on the notes, remarking upon the differences between Faye's documentation and hers. This led her to become interested in the structural effects of language attrition among members of speech communities. It also led her to her work among Nahuatl speakers since larger speech communities would facilitate statistic analysis.

Both Hill and her husband spent years researching the Mexicano Nahuatl-speaking communities in the Malinche region of Puebla and Tlaxcala, originally focusing on the structural impact of language obsolescence. But it was while doing this fieldwork that she began to move away from her roots in American structural linguistics, becoming more interested in the ways in which speakers use speech strategically and manipulate their knowledge of their local speech repertoires. She was also influenced by then emerging theoretical paradigms on the relationship between language, culture, and society: Hymes' initial elaboration of an ethnography of speaking; ethnomethodology; and, once translations of their work began to appear in the United States in the early 1980s, Bakhtin/Voloshinov (Hill 1985).

This intellectual shift led to one of Hill's first major publications, co-authored with her husband, *Speaking Mexicano* (Hill and Hill 1986). The book placed her at the forefront of new lines of inquiry in linguistic anthropology, which have significantly advanced the field in the last 20 years (Blount 1995, Grillo 1988). Eventually, Hill's interest in speakers' strategic deployment of linguistic resources led to her work on language and racism which establishes how Anglo-American speakers exploit language's indexicality by using deficient, ungrammatical, and spurious forms of Spanish (thus, 'mock' Spanish) to racialize Latinos (e.g., Hill 1993). Hill has also been working recently on historical linguistics, especially within the context of the history of the Uto-Aztecan peoples.

Hill began her teaching career at Wayne State University, where she became departmental head and active in the American Association of University Professor (AAUP) union effort. In 1983, she began teaching at the University of Arizona, where she is at present. Jane Hill was past president of the American Anthropological Association (1998–9) and is current editor of the influential journal *Language in Society.*

Hymes, Dell Hathaway (1927–)

N. H. Hornberger

Dell Hathaway Hymes was born on June 7, 1927 in Portland, Oregon and attended local schools there. He earned a BA in Anthropology and Literature at Reed College (1950), and MA (1953) and PhD (1955) degrees in Linguistics at Indiana University. He taught at Harvard University (1955–60), University of California, Berkeley (1960–65), University of Pennsylvania (1965–88), and University of Virginia (1987–98, now Emeritus), with short visiting and adjunct appointments at Princeton and Johns Hopkins Universities.

Internationally recognized for his contributions in linguistics, anthropology, folklore, and education, Hymes was a founder of sociolinguistics as it emerged in the 1960s. He was a founding editor (1972–1992) of the International Journal *Language in Society*, author, and editor of various publications, all of which played determining roles in shaping and directing sociolinguistics from its beginnings to the present.

Hymes' work has had a far-reaching impact on education, specifically in the development of ethnographic and linguistic approaches to education. His book co-edited with Cazden and John and published in 1972 was the first volume to call attention to the need to examine actual classroom interaction in order to understand the role of language in learning and teaching, setting an entirely new direction for educational research which continues to the present day. Hymes' programmatic call for ethnographies of communication—for descriptions of the 'ways of speaking' of diverse speech communities—was taken up by his students and colleagues, yielding such mainstays of the educational research literature as Heath's *Ways with Words* (1983) and Philips' *Invisible Culture* (1983), among innumerable others. His theoretical formulation of communicative competence as distinct from Chomsky's linguistic competence, which he first enunciated publicly at a research conference at Yeshiva University in 1966, has been a major guide-post in second language teaching and research ever since. As Dean of the University of Pennsylvania Graduate School of Education from 1975 to 1987, Hymes founded the Educational Linguistics Programs (1976) and the Ethnography in Education Forum (1980), among the first such initiatives in the country.

Among his many awards and honors, Hymes is a Fellow of the American Association for the Advancement of Science, a Life Fellow at Clare Hall, Cambridge University, and a member of the British Academy; he has also been a Fellow at the Center for Advanced Study in the Behavioral Sciences (1957–58), a Guggenheim Fellow (1969) and a Senior Fellow of the National Endowment for the Humanities (1972–73), among others. He was a trustee of the Center for Applied Linguistics (1973–78) and served as President of the American Folklore Society (1973–74), the Council on Anthropology and Education (1978), the Consortium of Social Science Associations (1982–84), the Linguistic Society of America (1982), the American Anthropological Association (1983), and the American Association for Applied Linguistics (1986).

Jaberg, Karl (1877–1959)

T. Hill

The Swiss dialectologist Karl Jaberg created, together with J. Jud, the Linguistic and Ethnographic Atlas of Italy and Southern Switzerland, and his writings on it are a major contribution to the theory of linguistic geography. Jaberg, a Bernese, was a student and teacher at Bern University, occupying the chair of Romance studies from 1907. An early influence was a period of study at Paris with Gilliéron

(see *Gilliéron, Jules*), whose method he expounded in *Sprachgeographie, Beitrag zum Verständnis des Atlas linguistique de la France* (1908). Another early influence was a field trip in the Grisons, collecting data for the Romansh dictionary, which led to his becoming a Romansh specialist, introducing this language in his courses at Bern. By 1908, Jaberg was collaborating with J. Jud, his opposite number at Zurich, on a project to survey the Italian and Rhaeto–Romance dialects of Italy and Switzerland. This project is discussed hereunder, under Jaberg's name (an entirely arbitrary placing, as both scholars contributed equally during their 30-year partnership).

The survey was intended, following Gilliéron, to capture the 'biology of language.' When each of the 2000 questionnaire items was presented to the informant for translation into the dialect, only his first response was noted, with comments on hesitations, etc., so as to record over all the dialect as such, its state of preservation, and attitudes to it. The team included the folklife specialist P. Scheuermaier, who made a survey of material culture, folklore, etc. Fieldwork began in 1908, was interrupted by World War I, and ended in 1925; funding after the war being insufficient, it was supplemented by the two scholars personally.

The eight illustrated volumes of the *Sprach- und Sachatlas Italiens und der Südschweiz* (usually abbreviated AIS, sometimes SSIS) came out between 1928 and 1943, preceded by a theoretical statement. Scheuermaier's two-volume *Bauernwerk in Italien, der italienischen und rätoromanischen Schweiz* appeared in 1945 and 1956. A place-name survey remained to be published. In 1933, Jaberg and Jud gave a series of lectures on the AIS at the Collège de France, Paris, home of Gilliéron's atlas. Jaberg's lectures were published in 1936 as Aspects *géographiques du langage*.

Dialectologists trained by Jaberg and Jud include Griera (Catalan) and Hotzenköcherle (Swiss German). In the 1930s, Jaberg was active on the coordinating board set up for the three Swiss Romance dialect dictionaries—Romansh, Italian, and French: and in 1942 he succeeded Gauchat as editor of this last, the *Glossaire de la Suisse romande*.

Jaberg's interests included the interpretation of lexical phenomena by reference to folk culture and psychology, and the study of linguistic border zones—an environment in which, through conflict between neighboring norms, specific semantic chan-ges occur, ambiguities arise, and morphological sys-tems are reconstructed. Examples can be found in *Aspects*, and in his collection of essays *Sprach-wissenschaftliche Forschungen und Erlebnisse*, published in 1937 as No. 6 in the series *Romanica helvetica*.

Kachru, Braj B. (1932–)

R. V. Pandharipande

Born into a Kashmiri *Pandit* family in Shrinagar, India, and trained in the Indian and the British literary and linguistic traditions, Braj B. Kachru is a scholar in general sociolinguistics, South Asian linguistics (especially Kashmiri grammar), and the field he has made his own, 'World Englishes.' The terms 'World Englishes' and 'Indian English' summarize the *mantra* of Braj Kachru's research and define the models for analyzing, describing, and authenticating non-native 'incarnations' of the English language in diverse sociolinguistic contexts.

In the 1950s, when 'English' meant essentially British or American English, Kachru's work on Indian English, influenced by Halliday (see *Halliday, Michael Alexander Kirkwood*), and Firth (see *Firth, J. R.*), rejected the dichotomy between form and meaning. His PhD thesis, *An Analysis of Some Features of Indian English: A Study in Linguistic Method*, claimed that the goal of linguistic analysis is to relate a text to the context of situation (1982: 10) and that Indian English should therefore be analyzed

in British or American cultural contexts. This approach challenged the prevailing theoretical, methodological, and pedagogical conceptualizations of English and promoted the notion 'World Englishes' (1982, 1983, 1986). His framework of three concentric circles (see *New Englishes*) provided a functional model for categorizing and differentiating all varieties of English.

Kachru's polymodel of English is based on multiple norms of acceptability, appropriateness, and intelligibility in culturally diverse contexts, which demand innovations and change in the form and function of the English language. He refers to this approach, after Firth, as the strategies of conceptualization of English. Kachru demonstrated the inadequacy of the traditional mono-model (based on the native institutionalized varieties of English) to recognize and describe the reality of the postcolonial period where English had adopted new norms of diverse cultural and linguistic identities (African English, Singaporean English, etc.) as a result of its

spread in different parts of the world (see *Language Spread*).

Kachru argued against treating features of non-native varieties as deviant, viewing them as 'new/altered meaning systems' of mixed codes, which underpin the bilingual's creativity. This proposal greatly influenced the interpretation of contact literatures of Asia, Africa, etc., which can be used as tools to reconstruct underlying cultural identities. Current research on formal and functional constraints on code-mixing owes its origin to Kachru's foundational work on Hindi-English code-mixing.

Kachru's work has influenced English language education across the globe, with non-native varieties of English increasingly being recognized as valid and the notion 'cultural competence' becoming part of the English language curriculum. Recipient of many prestigious awards and recognitions (including first prize for his book *The Alchemy of English* by the English Speaking Union of the Commonwealth), Kachru continues to be a spokesman for linguistic democratization of codes through the forum of the journal *World Englishes*, thereby enhancing our understanding of the relationship between language and society.

Khubchandani, Lachman M. (1932–)

R. K. Agnihotri

Lachman M. Khubchandani is the only Indian scholar who has seriously examined the Indian Census data on language extensively, making significant contributions to our understanding of the sociology of language, particularly in multilingual settings. In a large number of research articles, monographs, and books published from India and abroad, he has consistently used linguistic and cultural plurality as a vantage point to examine the conflicting pressures of 'mainstreaming and development' and 'minority languages and cultures' in the lives of a variety of speech communities.

Khubchandani was born in Karachi in 1932. He graduated from Panjab University where he studied Hindi and journalism. He did his doctoral work on the acculturation of Indian Sindhi to Hindi at the University of Pennsylvania (USA) for which he received his PhD in 1963. He worked as the Professor of Indian Linguistics at Zagreb University and was later a Senior Fellow of the East-West Center, Honolulu. In India, Khubchandani is affectionately known as a one-man institution because of the amount of quality work he has produced during the past 30 years. He is currently the Director of the Center for Communication Studies, Pune, which has produced a large number of monographs on several sociolinguistic issues including language planning, language demography, multilingual education, etc. He has taught at several universities in India, Yugoslavia, Singapore, the UK, and the USA and has often been invited as a language expert on India by UNESCO and the East-West Center, Honolulu. He has been a Fellow at the Indian Institute of Advanced Study, Shimla (Himachal Pradesh, India) where some of his most insightful work was produced.

Khubchandani worked extensively on a large number of speech communities including the Hindi-Urdu-Panjabi amalgam, the Panjabi diaspora and the Sindhis. He has also worked on the role of English in India trying to show how the future of English in India can only be secure if it becomes a part of the country's multilingual fabric. Indian multilingualism is characterized by flexibility and fluidity, with variability acting as a facilitator rather than as a barrier in communication. The Indian polyglot may often acquire several languages as a matter of course and may use one language at home, one with friends, another at work, and still another for academic and religious purposes. Khubchandani (1983: 167–75) talks of multilingualism in terms of whether it is organic or structural, and whether it is homogenizing or differentiating. Indian multilingualism is at once organic and differentiating whereas the American multilingualism is organic but homogenizing. Any codification and elaboration of language that ignores grassroots-level multilingualism becoming insensitive to ethnic identities and local literacies is bound to fail.

Kurath, Hans (1891–1992)
T. Hill

Hans Kurath, an American Anglicist of Austrian birth, was the founder and major directing force of the North American dialect surveys. His earliest appointments (from 1920) were in German and linguistics, but from 1946 he was professor of English language and literature at the University of Michigan, Ann Arbor, where he edited, with S. M. Kuhn, the *Middle English Dictionary* (1954 ff.), himself writing its *Introduction* (1952); he also published *A Phonology and Prosody of Modern English* (1964).

During the 1920s, Kurath and others made the preparations for a survey of English in the USA and Canada, funded by the American Council of Learned Societies. It was intended to compile half-a-dozen regional atlases: Kurath being general coordinator, and also director of the first two undertaken, viz. of New England, and of the other states of the Atlantic seaboard. The survey was to be on the Swiss model, gathering, along with lexical data, related information on material culture and folk life; and in 1931 J. Jud and P. Scheuermaier came from Switzerland to instruct the first field team. This included Kurath himself, B. Bloch, who participated for 12 years and trained many fieldworkers, including the future directors of the other atlases, G. S. Lowman Jr, the most active fieldworker until his accidental death in 1941, and E. B. Atwood.

The New England survey was carried out in the 1930s, supplemented by Lowman's collection of relevant phonological data in southern England (published in 1970 as Kurath and Lowman *The Dialectal Structure of Southern English: Phonological Evidence*). In 1939, Kurath, Bloch, and Lowman published the *Handbook of the Linguistic Geography of New England*, followed by the *Linguistic Atlas of New England* itself (1939–43). Fieldwork for the *Linguistic Atlas of the Middle and South Atlantic States* began in 1933 but was interrupted by the war,

and publication as such, by editors R. I. McDavid Jr. (see *McDavid, Raven Ioor, Jr*) and R. K. O'Cain, did not commence until 1980, 19 years after Kurath's retirement. However, Kurath had drawn on the combined data of the two surveys to compile *A Word Geography of the Eastern United States* (1949), and with McDavid *The Pronunciation of English in the Atlantic States* (1961), which also utilized Lowman's data on England, and was noteworthy *inter alia* for an elegant tabular scheme, from which can be read off concurrently a dialect's system of phonemes, and their articulatory particulars. A morphological study, *A Survey of Verb Forms in the Eastern United States* (1953), was contributed by Atwood.

Unlike the traditional dialects of Europe, those of North America consist in variations that arose relatively recently in the vernacular English of settlers and immigrants. Elicitation is therefore no simple matter of translation from standard into dialect, but requires techniques for capturing data in the flow of a directed conversation, and Kurath's methodology paid great attention to this. The surveys covered both rural and urban populations, the main network of 'folk speakers' being supplemented by a less dense one of speakers from the local elite and from the intermediate strata. This scheme has been criticized as insufficiently systematic (see Pickford 1956)—mainly reflecting the differing perspectives of dialect geography and sociolinguistics. Kurath's own theoretical approach is represented in his *Studies in Area Linguistics* (1972).

Labov, William (1927–)
D. Sankoff

William Labov has been the dominant figure in sociolinguistics since its emergence in the mid-1960s.

Having studied with Weinreich (see *Weinreich, Uriel*) at Columbia, he also taught there until 1970 before

founding the sociolinguistics program at the University of Pennsylvania, which has become the Mecca for the discipline.

Through Weinreich, Labov was exposed to the most progressive view of language extant in classical linguistics, its variability and changeability across space, time, speakers, domains and contexts. With Weinreich, Labov laid down a program for the empirical study of language in the speech community in 1968, thus making the bridge between the traditional study of language and the new field of sociolinguistics.

His 1963 MA project on a sound change in progress in Martha's Vineyard and his 1964 PhD thesis on sociolinguistic stratification of New York City introduced techniques of sample surveys, natural experimentation, and quantitative analysis into socio linguistic research. However, it was in his independent study of African American vernacular English in Harlem starting in 1965 that he made the paradigmatic breakthroughs underlying the modern field of linguistic variation theory. Labov's intent was an empirical, rigorous, and reproducible approach to language as it is actually used, a scientific linguistics. His ambivalence about the label 'sociolinguistics,' in analogy to other hyphenated domains like psycholinguistics, educational linguistics, etc., reflects his overarching project of advancing linguistic theory by grounding it in solid data and objective analyses rather than unverifiable intuitions and polemic debate, without sacrificing the creative roles of scientific insight and intricate inductive and deductive reasoning. Key components of this approach include the following:

(a) The resolution of Saussure's paradox through the notion of the linguistic variable. This is an explicit way of measurably linking the important structures of linguistic theory with time and other extralinguistic factors, through the quantitative effects of these factors on the choice among two or more different articulations of a given phonological form in a given context, involving no change in the denotational value of a lexical item, or the syntactic function of an affix.

(b) Principled sampling procedures, together with sufficient demographic, social, and linguistic characterization of the speaker within the speech community.

(c) Fieldwork methods designed to circumvent observer effects when eliciting and recording spontaneous speech samples of varying register in natural context, as well as quality control technology for speech data collected in field conditions.

(d) Scientific respect for the speech corpus, including data preservation and the principle of accountability, whereby *all* tokens in the corpus of the structure under study must be included in the analysis and calculations.

(e) Multivariate quantitative models of performance for attributing usage tendencies to linguistic and extralinguistic factors (see *Statistics in Sociolinguistic*s). This work made it possible to investigate questions of central interest to linguistic theory using statistics, based on the linguistic variable.

(f) Research-based advocacy for minority speech communities. He was the first to study and 'revalorise' minority and vernacular speech forms. He fought against Bernsteinian views of working class language, against the deficit hypothesis and against elitist language attitudes in the educational establishment (see *Code, Sociolinguistic; Bernstein, Basil*). This linguistic activism is clear in his choice of communities to study, in his recruitment of students, in his writings, in his advocacy in the courts, and in the media.

This program, carried out by Labov, his students and disciples worldwide, has met with undeniable success. The principles of sound change he established and the universal and language-specific constraint hierarchies he discovered have had a great impact on phonology and other areas of linguistics. His studies of t/d deletion, auxiliary contraction, and others have been replicated many times and have served as models for entire research traditions in New World Spanish, Canadian French, Brazilian Portuguese, and other languages. However, despite its unwavering focus on the linguistics of spoken language, or perhaps because of it, the intellectual power of this approach (studying usage instead of intuition, and concentrating on the elucidation of linguistic structure in social and historical context rather than using predefined language features as tools for properly social science investigations), it has revolutionized many other disciplines within language science.

His Harlem work, followed up by a generation of students in the US and the Caribbean, rescued the field of creole studies from its ethnolinguistic backwater to become one of the most intellectually rigorous and socially relevant ongoing research areas.

His long-standing interest in the vowel system of American English, particularly the Northern Cities Shift (see *Chain Shifts*) and the relationships among English dialects worldwide, has profoundly changed dialectology. Based on his experience in urban speech communities, he was able to dramatically increase the social validity of survey studies, while introducing new techniques and technology to increase efficiencies and to multiply the kinds of discovery possible. This work culminated in the monumental Atlas of

North American English (see *The Atlas of North American English: Methods and Findings*), whose computer-based methods have transformed dialectology.

Labov made many contributions to the analysis of narratives (see Bamberg 1997; *Narrative, Natural*). While his deep insights into the transformation of everyday experience into narrative would be hard to rival, the example he set, and the protocols he established for the analysis of narrative discourse have inspired a proliferation of research in this area. In the study of social change, Labov's gender and class-based models of language variation and change remain fundamental for the understanding of the prestige and influence of sociodemographic groups, culturally-specific gender roles, and the modeling and quantitative dynamics of trait diffusion within the community.

Labov's role in the field is attested to by his presence as invited speaker at the large majority of the 30 annual NWAVE (New Ways of Analyzing Variation) conferences, the premier sociolinguistics meeting, since 1972. He founded and is the guiding spirit behind the major variation theory journal, *Language Variation and Change* (1988–). He was president of the Linguistics Society of America in 1979. In 1993 he became one of the very few linguists ever elected to the National Academy of Sciences of the USA. He has been awarded honorary doctorates by numerous universities worldwide. His field methods and quantitative analysis protocols are taught in sociolinguistics classes everywhere. PhD students who have studied with him include many of the top researchers in sociolinguistics and related areas today: S. Ash, J. Auger, J. Baugh (see *Baugh, John*), C. Boberg, A. Bower, S. Boyd, M. Braga, P. Cohen, B. Dayton, P. Eckert, G. Guy, N. Haeri, J. Hibaya, D. Hindle, M. Lennig, B. Lavandera, C. Linde, J. Myhill, N. Nagy, G. Nunberg, N. O'Connor, M. Oliveira, C. Paradis, P. Patrick, S. Poplack (see *Poplack, Shana*), J. Rickford (see *Rickford, John Russell*), J. Roberts, D. Schiffrin (see *Schiffrin, Deborah*), F. Tarallo, B. Wald, J. Weiner, M. Yaeger-Dror and many others, while scores of post-doctoral students and scholars on sabbatical have also worked with him.

Lakoff, Robin Tolmach

J. Bennett

Robin Lakoff is widely recognized as one of the first linguists to acknowledge gender as a powerful, complex, and nuanced influence on the relation between linguistic form and social practice. Her position as feminist-sociolinguist pioneer is however logically linked to her overarching concern with connections between the institutionalization of power, discourse, and the philosophy of language.

Robin Lakoff graduated from Radcliffe College in 1964, where she majored in both classics and linguistics. She developed these joint disciplinary interests through an MA with Indiana University (1965) and a PhD in linguistics from Harvard (1967), where her dissertation laid the foundations for her first book *Abstract Syntax and Latin Complementation* (1970). Trained as a classicist and a syntactician, her work on connections between power and language often relies on rigorous and detailed analysis of the interplay between syntax, lexical choice, and conversational patterning. Lakoff held a post-doctoral fellowship in the Department of Linguistics at MIT, where she was one of a circle of

linguists working with Chomsky's early work on transformational grammar, and then moved to the University of Michigan as Assistant Professor of Linguistics (1969–1972). Since 1972, Robin Lakoff has been located at the University of California, Berkeley, in the Linguistics Department.

A key difference between Lakoff and one of her renowned contemporaries in the field of gender and language, Deborah Tannen, lies in Lakoff's explicit interest in the issue of power for women. Grounded in the feminist activism of the 1970s in the USA, Lakoff wrote *Language and Woman's Place* in 1975 as an initial exploration of a then-unpopular hypothesis: the notion that gender made a difference to function and meaning in language usage. *Language and Woman's Place* illustrated that in US English, it was possible to demonstrate gender's relevance to usage of hedges, intonation patterns, tag questions, the negotiation of politeness conventions, and other linguistic elements. The book, a slim volume, sparked a wave of interest among sociolinguists in gender analysis, and offered a new route into the theorization of social power.

Lakoff has since published several books which explore the relationship between social power (channeled through race, gender, age, institutional affiliation, or professional paradigm) and individuals' pragmatic location as speakers, listeners, and interpreters of meaning. She has particularly concentrated

on the language of the courtroom (*Talking Power: The Politics of Language in our Lives*) and of psychotherapy (*When Talk is Not Cheap* and *Father Knows Best: the Use and Abuse of Therapy in Freud's Case of Dora*). *The Language War* expands these interests into the discussion of news events in the US which have captured intense media attention both nationally and globally: the Anita Hill/Clarence Thomas hearings, the role of Hillary Rodman Clinton as First Lady, the Clinton sex scandal, the Eubonics controversy, and others. Lakoff's arguments chart the US media's use of language in shaping social policy, individuals' access to comprehension of the news, and public attitudes on highly-profiled events.

Lambert, Wallace E. (1922–)
G. R. Tucker

Wallace E. Lambert was born in 1922 in Amherst, Nova Scotia although his family moved shortly thereafter to Taunton, Massachusetts where he spent his formative years. After a hiatus caused by service in the US Army during World War II, he received his BA in Psychology from Brown University (1947), his MA in Psychology from Colgate (1950), and his PhD in Psychology from the University of North Carolina (1953).

Lambert spent his entire professional career as a faculty member in the Psychology Department at McGill University which he joined in 1954. He continues this association as Professor Emeritus. By virtue of his prolific research, publication, and teaching, Lambert has had a profound and positive influence on educational policy and practice throughout the world. His early work on the relationship of bilingualism and intelligence (Peal and Lambert 1962) constituted a landmark contribution to the

field. The course of inquiry into the nature of the correlates and consequences of individual bilingualism was significantly altered following the pioneering contributions by Lambert and his students. The publication of their research resulted in a 'paradigm shift' within the field.

Similarly, his early work with Gardner on the role of motivation and attitudes (Gardner and Lambert 1972) foreshadowed the development of a specialized subfield of educational linguistics—a concern with the role of individual differences in second language learning and teaching. His subsequent applied research into the effects of foreign (or second) language immersion on the cognitive, social, and educational development of English-speaking youngsters in the Province of Quebec (Lambert and Tucker 1972) likewise profoundly influenced the design and implementation of educational programs for both language minority and language majority students

throughout North America (Cazabon et al. 1998). Lambert's early work led directly to an educational model referred to in the United States as Developmental Bilingual Education—that is, programs in which language minority and language majority youngsters spend some portion of the day *together* studying via one (or the other) target language to provide cross-language peer-group tutoring. This work has affected the course of subsequent (language) education for thousands of North American youngsters.

In later years, Lambert's interests focused more sharply on understanding the educational, social, and personal consequences of the increasing heterogeneity of North American society (e.g., Lambert 1992, Lambert and Taylor 1990, Taylor and Lambert 1996). As he and his colleagues pursed their research in multicultural and multilingual communities such as Detroit, Michigan or Miami, Florida, Lambert continued to argue that ethnic minorities in North America can effectively and comfortably double their cultural identity ... that 'they can have two cultures and two languages for the price of one' (Lambert 1991).

Lambert himself has often noted the important role that his family—his wife Janine Fraissinet from France, and his children Sylvie and Philippe—played in introducing him firsthand to the underlying issues of language, culture, and identity that became so prominent in his own research.

Le Page, Robert (1920–)

A. Tabouret-Keller

In 1950 Robert Le Page went as lecturer in English to the University College of the West Indies in Jamaica, where he met the Jamaican-American F. G. Cassidy. They formed a group, and in 1960 called a conference around their new field of *Creole language studies.* Together they published the *Dictionary of Jamaican English* (1967) which has remained a standard work. In 1964, Le Page in addition promoted the study of *The National Language Question*, which he produced for The Institute of Race Relations. Since then he has focused on a sociolinguistic approach to the study of speech via 'Acts of Identity' (see *Identity and Language*). He was particularly interested in stereotypes of *a language* as a discrete finite rule-system and their relationship to the realities of observed linguistic behavior. Le Page proposed a new framework for the definition of languages as systems inherent in the behavior of networks of individuals and as linguistic and political artifacts. To the extent that a speaker's behavior is reinforced through interaction, it may become more regular and *focused*; to the extent that he modifies it to accommodate others, it may become more variable and *diffuse*. Thus linguistic systems, both in individuals and in groups, may be considered as focused or diffuse. He was able to submit these views to a series of workshops—in 1986, 1988, 1990, and 1992—of the International Group for the Study of Language Standardization and the Vernacularization of Literacy.

Le Page was born in London on December 8, 1920. After war service in the Fleet Air Army (1940–45), he took his BA at Oxford (1945–48). His PhD dissertation (*Studies in Early English Prosody*) was accepted by Birmingham University in 1952. His time as Professor of English and Dean of the Faculty of Arts at the University of Malaya in Kuala Lumpur (1960–64) was followed by his appointment to the Chair of Language and Linguistic Science at the new University of York in England, where he was also for a time Provost of Vanbrugh College (1967–73). He finally retired in 1988, becoming Professor Emeritus and continuing to publish on linguistic topics.

Lewis, E. Glyn (1920–94)

D. Brown

E. Glyn Lewis was a Welsh educationist who worked for the ministry of education in charge of bilingual education for England and Wales for a period of 20 years. His research work focused mainly on comparative perspectives of language education and policy in a wide range of countries. As a result he collaborated with a very wide network of international scholars. His work provided important comparative international research in language education.

Lewis was educated at the University of Wales and at Oxford. He taught in grammar schools and at the University of Wales, where he was director for the research project of the school council at the University of Wales, Swansea. His publications on bilingual education began in the 1950s with reports on the role of English in Welsh schools and bilingual education. He organized and reported on the International Seminar on Bilingualism held under the auspices of UNESCO in the 1960s in Aberystwyth, Wales. His network of international contacts placed him in a pivotal position to deal with bilingual education in international perspective. His contacts ranged from G. A. Senyuchenko, the Soviet scholar, to E. G. Malherbe, the South African educationist who researched bilingual education. As a consequence he developed an interest in language education in the Soviet Union which resulted in a substantial text on multilingualism in the Soviet Union (1972), the fruits of a delegation to study language education in the Soviet Union under the auspices of the British Council.

Lewis brought an historical and comparative depth to the study of bilingual education, adding understanding to the social and political circumstances that give rise to language education policy. The fruits of his long association with language education were published in a work entitled *Bilingualism and Bilingual Education: A Comparative Study* published in 1980. This work was produced while resident at the University of New Mexico where he continued his productive association with Bernard Spolsky, the noted American scholar of bilingualism. The study is an in depth analysis and comparison of bilingual education in ten countries.

He included a study of the implementation of language education amongst minority groups such as Native Americans in his study. Spolsky compliments Lewis with having made American scholarship aware of the full extent of the international research into bilingual education.

In his comparative work Lewis reports on the limitations of bilingual education and its problems and presents the research done in the 1970s in Wales on the potentially detrimental effects of what he refers to as uncoordinated bilingual education. Importantly Lewis believed in the ethical dimension of language education and his work shows an acute awareness of the social circumstances, which give rise to language education policy such as immigration, refuge, and forms of social inequality. He believed ultimately that tolerance and ethical issues in language education were more important than the scientific nature of language research.

Malinowski, Bronislaw Kaspar (1884–1942)

A. T. Campbell

Malinowski was born in Cracow, Poland. He was the son of a well-known Slavic philologist (Lucyan Malinowski). After a PhD in physics and mathematics, he turned to anthropology, inspired, he said, by a reading of Frazer's *Golden Bough*. In 1910 he arrived at the London School of Economics, and in 1914 began anthropological fieldwork in New Guinea. Between 1915 and 1918 he did two years fieldwork on the Trobriand Islands (off Papua New Guinea). After some years teaching at the LSE he was appointed to the first Chair of Anthropology there (1927). In 1938 he went to the USA where he was appointed professor at Yale. He died in New Haven at the age of 58.

In the three great ethnographies of the Trobriand Islands (*Argonauts, Sexual Life*, and *Coral Gardens*), Malinowski established the tradition of intensive fieldwork, participating in the life of the society being studied, emphasizing the effort to appreciate a total view of the society and to understand matters 'from the natives' point of view.' He constantly emphasized the importance of learning and working with the indigenous language. The vivid style of writing and the colossal amount of detail have established these ethnographies as classics. The account of the *kula* ring, a complex system of formal gift giving described in *Argonauts*, is one of the most celebrated cases in anthropology.

In terms of sociological theory, Malinowski's functionalism and his ideas about 'basic needs' are pretty banal, and are only of interest as indicating an important shift in anthropology away from questions about origins and evolution which had previously been so dominant. On the other hand, his concern with language is much more fruitful. He was proud of his ability to pick up languages quickly, and, as well as insisting on the importance of conducting field research in the native language, he shows an intense concern with the processes and details of translation (*Coral Gardens*, vol. 2). He laments the lack of sound ethnolinguistic theory. Although his attempt to provide one does little with regard to phonetics, phonology, or grammar, his writing on meaning is

original. In a remarkable essay (1923) appended to Ogden and Richards' *The Meaning of Meaning*, he coined the phrase 'phatic communion' (gossip, pleasantries, and so on) to make the point that language should not just be seen as a vehicle for thought through which to communicate ideas, but as a mode of action which, in this example, establishes personal bonds between people. Also in this essay he claims originality for the notion of 'context of situation' in an argument which prefigures Wittgenstein's 'the meaning of words lies in their use,' developed in *Philosophical Investigations*.

J. R. Firth wrote: 'I think it is a fair criticism to say that Malinowski's technical linguistic contribution consists of sporadic comments, immersed and perhaps lost in what is properly called his ethnographic analysis' (1957: 117). But beyond a strictly 'technical' contribution, his expertise in translating from Trobriand and his writing on meaning and translation deserve a more generous judgment.

Mazrui, Ali A. (1933–)

A. M. Mazrui

Ali A. Mazrui is best known for his contributions to the political sociology of language in Africa.

Over the years he has regarded language as a meeting point between the world of politics and the

891

world of culture and between his African and global concerns.

He was born in Mombasa, Kenya, on February 24, 1933. Mazrui received his PhD in political science from Oxford University, UK. He began his university career at Uganda's Makerere University in 1961, moving to the USA ten years later. In 1974 he was appointed professor at the University of Michigan. In 1991 he became the Albert Schweitzer Professor and Director of the Institute of Global Cultural Studies at the University of Binghamton. Mazrui has also held visiting professorships in several universities in five continents.

In 1979 Mazrui delivered the prestigious annual Reith Lectures of the BBC on the *African Condition*. He is also the architect of the internationally acclaimed 1986 PBS-BBC television series, *The Africans: A Triple Heritage*. He has authored over 20 books and hundreds of scholarly articles. Recipient of numerous honors and awards, Mazrui has been a fellow and office bearer of many professional organizations throughout the world.

Much of Mazrui's sociolinguistic work has focused on the role of European languages in Africa. He initially regarded European languages as allies of political liberation and facilitators of expanding intellectual horizons. His book, *Political Sociology of the English Language*, written in the 1960s but published in 1975, was deeply influenced by such linguo-optimism.

This line of sociolinguistic thinking continued after the mid-1970s—but now primarily because he regarded European languages as indispensable for the development of world culture. And yet this is a period when Mazrui was trying to strike a balance between the global and the local. In his *A World Federation of Cultures* (1976) he articulates a preferred world in which every child has to learn three languages—one global, one regional, and the third either national or subnational.

By the late 1980s Mazrui became more concerned about protecting indigenous languages than he was before, now seeing European languages as potentially corrosive forces on indigenous legacies. This imperial linguopessimism became more pronounced in the 1990s when he joined forces with Alamin M. Mazrui to produce *Power of Babel: Language and Governance in the African Experience* (1998).

Mazrui has also been fascinated by the role and impact of Kiswahili (his mother tongue) in East Africa. He has examined the role of the language in political participation, nation-building, labor unions, family life, and regional integration. He and Alamin M. Mazrui came together to produce another book, *Political Culture of Language: Swahili, Society, and the State* (1996).

Perhaps more than any other African thinker of the twentieth century, Mazrui has continuously attempted to enrich the language of social analysis with new coinages of his own such as *Afro-Saxons* (Africans who speak English as a first language), *Afrabia* (the paradoxical intimacy between Africa and Arabia), *counterpenetration* (Third World leverage in the powerful West), *romantic gloriana* (a form of cultural nationalism which glorifies national history), *lumpenmilitariat* (rough and ready soldiers capturing power) and many others.

McDavid, Raven Ioor, Jr (1911–84)
T. Hill

Raven Ioor McDavid, Jr, dialect geographer and sociologist of American English, was born in 1911 at Greenville, South Carolina, and attended Furman University there. Initially a literary specialist, he was drawn to the study of American English by reading *The American Language* by H. L. Mencken, and their ensuing correspondence played a major role in his early development. From 1935 to the early 1950s, McDavid taught English and modern languages at various universities, and while he was at Southwestern University, in 1941, H. Kurath (see *Kurath, Hans*) recruited him as fieldworker for the *Linguistic Atlas of the Middle and South Atlantic States*. His work began with training by B. Bloch, was

interrupted by war service (1942–47), but was resumed and completed by 1949. The atlas, edited by McDavid and R. K. O'Cain, was not published until 1980 ff.; but studies published in the interim include Kurath and McDavid's *The Pronunciation of English in the Atlantic States* (1961), to which McDavid contributed a major study of the regional and social variants of individual words.

In the 1950s, while at Western Reserve University, Cleveland, McDavid was a fieldworker for several regional atlases, viz: the Rocky Mountain States; the Upper Midwest (states west of the upper Mississippi); and the North Central States (i.e., from the Great Lakes to Kentucky)—becoming associate editor of the last, and eventually publishing its field records, with R. C. Payne, in 1977. His wife and collaborator, Virginia G. McDavid, contributed the morphological study *Verb Forms of the North Central States and Upper Midwest* (1957). During this period, U. Weinreich (see *Weinreich, Uriel*) initiated the debate on the possibility of a structural dialectology, and in 1961 McDavid reviewed the discussion in 'Structural linguistics and linguistic geography' (*Orbis* **10**: 35–46; reprinted in Kretzschmar 1979).

From 1964 to retirement in 1977, McDavid occupied a chair at the University of Chicago. The last major region not yet surveyed was the Gulf States (Texas to Florida), and the survey was set up in 1968 with McDavid and L. Pederson as directors. The survey handbook, *A Manual for Dialect Research in the Southern States* (L. Pederson et al. 1972, 1977), includes a section on 'Field procedures' by McDavid; in it, he discusses with native insight and affection the approach of the fieldworker to this distinctive culture, and stresses the importance of collecting cultural as well as dialectal data.

McDavid's wider interests lay, as he said, in 'the relationships between linguistic patterns in the American speech community and the complex of social forces in American society.' This included lexicography, in the USA a battleground between authoritarians and descriptive linguists. Accordingly, he was involved not only in the preparations for F. G. Cassidy's *American Dialect Dictionary*, but also in the controversy following the publication of *Webster's Third New International Dictionary* (1961). In 1963 Mencken's *American Language* was republished in a one-volume abridgment by McDavid, enhanced by his numerous additions and comments. Various other publications reflect his concern about the linguistic obstacles to the betterment of the poor, including the problems of 'Black English.'

Milroy, Lesley (1944–)

Li Wei

Lesley Milroy is Hans Kurath Collegiate Professor of Linguistics at the University of Michigan, USA. She is a sociolinguist with a broad range of interests and expertise. She has published widely on rural and urban dialectology, variation theory, the interface between phonetics/phonology and sociolinguistics, language ideology and language standardization, bilingualism, and aphasia and agrammaticism. She is, however, best known for her pioneering work in Belfast in the 1970s where she applied social network analysis to the study of linguistic variation and change.

Born in Newcastle upon Tyne, UK, Lesley Milroy was educated at the University of Manchester where she read English language and literature and obtained a First Class Honours degree in 1965 and an MA in 1967. She received a PhD from Queen's University, Belfast in 1979. She worked in Ulster Polytechnic (now University of Ulster) as a Principal Lecturer before taking up the Senior Simon Research Fellowship at the University of Manchester in 1982. She returned to her birthplace in 1983 and became Professor of Sociolinguistics in the Department of Speech, University of Newcastle upon Tyne until 1994. In 1994 she joined the University of Michigan, Ann Arbor, USA.

Lesley Milroy's work in Belfast, which was carried out in collaboration with James Milroy and others, was concerned primarily with how a stable set of

linguistic norms emerges and maintains itself in a community. Lesley Milroy calls these *vernacular norms*, norms which are 'perceived as symbolizing values of solidarity and reciprocity rather than status, and are not publicly codified or recognized' (1980: 35–6). These norms contrast with middle-class norms, the ones most of us would view as being characteristic of any wide social standard.

Consequently, Milroy focused on working-class speech in three stable inner-city communities. Through participant observation and a sophisticated statistical analysis of social networks—personal relationships of various kinds that are developed over time, she was able to show that 'a closeknit network has the capacity to function as a norm enforcement mechanism; there is no reason to suppose that linguistic norms are exempted from this process. Moreover, a closeknit network structure appears to be very common ... in low status communities' (ibid. p. 43). The Belfast study was a novel synthesis of Labov-type quantitative-variationist work in social dialectology (see *Sociolinguistic Variation*) and Gumperz-style interactional work in the social anthropology of language (see *Interactional Sociolinguistic Research Methods*).

While the application of the social network analysis has caught the imagination of the socio-linguistics research community at large, a major contribution of Milroy's work was her use of the ethnographic approach which produced explanations for the nature of language variation in a complex urban community of a type that could not have been revealed in any other way. Her work also demonstrates the importance of linking fieldwork methodology and data collection with the analysis and interpretation of the data and with the linguistic theory and model one aims to validate.

Since the Belfast study, Lesley Milroy has investigated sociolinguistic variation and change in a number of urban contexts, including Newcastle upon Tyne in the UK and Detroit in the USA, focusing on the role of social class, social network, and gender. She has also applied the social network model to the study of language maintenance and language shift in multilingual communities. In recent years, Milroy has attempted to develop coherent models linking the macrosocietal and microinteractional levels of sociolinguistic analyses. To this end, she has examined language ideology, language attitude, and life mode, and their influence on the speaker's language behavior. Her interest in the inter-actional dimension of sociolinguistics has led to her work in Conversation Analysis (see *Conversation Analysis*), which aims to deal with irregular data of various kinds, notably bilingual code-switching and aphasic conversational data. She has exploited the potential of Conversation Analysis to illuminate some key issues in interactional sociolinguistics.

Lesley Milroy has lectured worldwide and served on the editorial boards of key sociolinguistics journals and book series.

Mufwene, Salikoko S. (1947–)

R. Mesthrie

Salikoko Mufwene was born in Zaire (now Democratic Republic of Congo) and educated at Lovanium University and the National University of Zaire at Lubumbashi, graduating from the latter with a *Licence en Philosophie et Lettres* (BA), *Group Philologie Anglaise* 'with highest honours.' He completed a PhD at the University of Chicago with a dissertation on semantics. Mufwene started his university teaching career in the Caribbean at UWI Mona, Jamaica in 1980. He subsequently joined the faculty at the University of Athens, Georgia. He moved to his alma mater the University of Chicago in 1991, where he has been departmental chair since 1995.

Mufwene has worked in semantics and syntax, to which he has contributed theoretical studies of English, French, Gullah, Caribbean English creoles, African American Vernacular English, and Bantu languages such as Lingala and the two languages he grew up speaking, Kikongo-Kituba and Kiyansi. He has also contributed to the fields of anthropological linguistics (see *Anthropological Linguistics*), general

sociolinguistics and language contact studies. But it is to the field of creole genesis that he has made the most significant and innovative contributions. Mufwene's strengths are his intimate knowledge of several substrates, two superstrates and several creoles. A voracious reader in the creole literature in English and French, he is no mere synthesiser. Known for his original and not always popular positions, Mufwene has ensured the field of creolistics does not remain static. He has always insisted on a close scrutiny of seemingly sacred positions, as witnessed in the important 1986 paper, 'The universalist and substrate hypotheses complement one another' (the 'complementary hypothesis'). He enunciated most clearly the founder principle in creole genesis in 1996. More recently he has advocated an approach that does not take for granted a special status for pidgins and creoles, but sees them in terms of other contact phenomena, as well as of population movements in general. This work, inspired by population genetics, especially macroecology is published as *The Ecology of Language Evolution* (2001). The work has implications for Pidgin and Creole Studies, language contact generally, historical linguistics, as well as the history of American English. It proposes that creoles have evolved by the same evolutionary processes observable in the histories of noncreole languages, by competition and selection of features from a gene pool to which xenolectal features also made substantial structural contributions. The challenge is to work out what principles regulate the selections both among languages engaged in contact and among their respective features, while the prevailing language is clearly targeted by all speakers. Mufwene also argues that genetic linguistics can learn a lot from issues addressed in genetic creolistics, especially by factoring in contact in order to answer the 'actuation problem' in language diversification. The same competition-and-selection account is also used in the book to discuss mechan-isms of language endangerment. In collaboration with his students, Mufwene has produced a translation of the French creolist Chaudenson's work into English, as *Creolization of Language and Culture* (2001).

Mufwene's success from humble beginnings has not gone unnoticed: he is listed in Marquis' *Who's Who in the South and Southwest* (1986) and *Who's Who of Emerging Leaders in America* (1987), as well as in *Men of Achievement* (International Biographical Centre, Cambridge, England). He has been a regular and provocative columnist for *Journal of Pidgin and Creole Languages*, a regular and incisive reviewer for many journals, and is founding editor of the Cambridge University Press series, *Approaches to Language Contact*. Amongst his hobbies are disco-dancing (Congolese, Reggae, Calypso, Salsa, Juk), travel, the cinema, and reading on population genetics, macroecology, and colonial history.

Mühlhäusler, Peter (1947–)

P. Baker

Peter Mühlhäusler is best known for his work on pidgins, particularly Tok Pisin of Papua New Guinea, but he has also published on such diverse topics as pronominal grammar, language planning, and the linguistic influence of missionary policies. However, his recent and continuing studies in language ecology could ultimately prove his most important contribution to linguistics.

Mühlhäusler was born in Freiburg, Germany, where he attended a gymnasium, but his tertiary education took place in three other countries. In 1969, he completed a BA (Hons) in Afrikaans-Dutch (with Linguistics, Gothic, Old Norse, and Medieval Literature) at Stellenbosch University, South Africa. He then wrote an MPhil thesis on *Pidginization and the Simplification of Language* at Reading University

895

(UK) in 1972. He completed his studies with a PhD thesis on New Guinea pidgin in 1976 (published in 1979) at the Australian National University.

After teaching at the Technical University of Berlin, he became lecturer in General Linguistics at the University of Oxford in 1979. It was during his time at Oxford that two of his most influential books were published, *Pidgin and Creole Linguistics* (1986) still widely considered to be the best single-authored volume on this topic, and *Pronouns and People* (Mühlhäusler and Harré 1990). It was also during the 1980s that he began the collaboration with Stephen Wurm and Darrell Tryon which was to lead to the massive *Atlas of Languages of Intercultural Communication in the Pacific, Asia, and the Americas*, completed a decade later (1996).

Since 1992, Mühlhäusler has been Professor of Linguistics at the University of Adelaide in South Australia. While in Australia, he has taken a growing interest in the relationship between language and environment, and is one of the pioneers of the new field of Ecolinguistics. This has already led to the publication of two books (1996, 1999) and more than a dozen articles while a third book has also been completed and is expected to appear by the end of 2001.

Mühlhäusler's greatest achievement to date has been to bring to the study of pidgins the rigor, which was formerly lacking. His influence, not only in pidgin and creole studies but far more widely, is due both to the breadth and depth of his interests and knowledge across the whole field of linguistics and to his productivity as an author, having published perhaps 200 books, articles, and book reviews over the past 20 years.

Muysken, Pieter Cornelis (1950–)

A. Bruyn

Pieter C. Muysken's work extends into several branches of linguistics, including generative grammar and morphology alongside sociolinguistics. Broad-minded and striving for the integration of different perspectives, Muysken is involved in descriptive and theoretical linguistics, with a focus on language contact, bilingualism, second-language acquisition, code-switching, and the emergence of new languages. A central issue in his work is the diversity within and between languages, and the structural, cognitive, and sociolinguistic factors determining such diversity and its limits.

Born on April 11, 1950, Pieter Cornelis Muysken spent the first six years of his life in Bolivia and Peru, where he learned to speak not only Dutch, the language of his parents, but also English, Spanish, and Quechua. After a Dutch education, he obtained a BA in Latin American Studies and Spanish at Yale College (New Haven, Connecticut), then continued his linguistic studies at the University of Amsterdam (The Netherlands). He received his PhD in 1977, his dissertation dealing with the verb phrase in Ecuadorian Quechua.

During his fieldwork in Ecuador, Muysken discovered the Media Lengua (lit. 'half(way) language'), a socially, as well as linguistically, intermediate variety between Quechua and Spanish. Muysken (1981, 1997) attributes its origins to relexification, with Quechua stems replaced by Spanish ones with similar meanings, among Quechua speakers working in a Hispanic environment.

The existence of mixed languages such as Media Lengua aroused Muysken's interest in code-switching and -mixing. In *Bilingual Speech* (2000), he distinguishes different types of code-mixing, and explores how these may depend not only on structural-typological factors, but also on psycholinguistic and sociolinguistic aspects of different bilingual settings.

From 1976 until 1998, Muysken was attached to the Institute for General Linguistics of the University of Amsterdam, first as a lecturer, then as Professor of General Linguistics, in particular Sociolinguistics

and Creole Studies. Lively and charming, he kindled the enthusiasm of scores of students, some of them continuing with dissertation projects under his direction. He was involved in the organization of several workshops on creole languages, papers from one of which appeared as *Substrata Versus Universals in Creole Genesis*, edited by him and Norval Smith (Muysken and Smith 1986). With René Appel, another colleague of many years standing, he wrote a textbook on language contact and bilingualism (Appel and Muysken 1987). He also instigated the joint enterprise *Pidgins and Creoles* (Arends et al. 1995), which contains contributions by himself and his Amsterdam colleagues and students. His interest in the study of creole languages includes the search for universals, in terms of processes as well as properties. Among the creoles he has investigated are Papiamento and Negerhollands.

After an interlude as Professor of Linguistics and Ibero-American Linguistics at Leiden University, he became Professor of General Linguistics at the University of Nijmegen in 2001. In 1998 he was awarded the Spinoza stipend of the Netherlands Organization for Scientific Research (NWO), which enabled him to set up a research program focusing on the interaction between lexicon and syntax at various levels. One of these is language contact and change; this involves a number of areal studies and the construction of a typological database. Another level is that of I(nternal)-language. It is anticipated that this will involve experimental study of the relation between syntactic and lexical processing in sign language and bilingual language use.

Myers-Scotton, Carol

S. Gross

Carol Myers-Scotton is one of the world's leading figures in code switching and language contact research. She has published scores of articles and books on subjects as diverse as the sociopragmatic motivations for code switching, the grammatical constraints governing intra-sentential code-switching, bilingualism, borrowing, creole and mixed language formation, discourse analysis, and stylistics. In all of her writings, Myers-Scotton is concerned with examining the link between language production and its underlying universal cognitive mechanisms.

Carol Myers-Scotton received her PhD in linguistics from the University of Wisconsin at Madison in 1967 with a dissertation on the syntactic and semantic restrictions of the Swahili extended verb system. After receiving her PhD, she traveled to East Africa, on numerous occasions, to conduct sociolinguistic fieldwork in the multilingual settings of Kenya, Tanzania, Zimbabwe, and Malawi. During this time, she began to focus her efforts on studying the complex code switching strategies used by the people she encountered. This fieldwork sparked a lifelong study of code switching, its social aspects, and its structural features.

In 1993, Myers-Scotton published two important books on code switching. In *Social Motivation for Code Switching: Evidence from Africa* (1993a) Myers-Scotton develops her markedness model to explain the linguistic choices that multilingual speakers make. In the markedness model, linguistic choices are seen as deriving from the speaker's desire to optimize the outcomes of an interaction. In *Duelling Languages: Grammatical Structure in Code Switching*, (1993b) she presents a formal grammar of intrasentential code switching, the matrix language frame model. Under the matrix language frame model, the language varieties that participate in code switching play different roles in building a syntactic structure. This asymmetry is played out by allowing only one participating variety as the source of the grammatical frame in a bilingual sentence, the matrix language. The role of the other variety is largely restricted to contributing singly occurring content morphemes in mixed constituents.

897

Since the publication of these two books, Myers-Scotton has developed two interlocking models of morpheme activation, the 4-M model and the abstract level model, which hypothesize that four different types of morphemes are activated at different levels in language production. Myers-Scotton and her associates have used these two models to explain the structural outcomes in a wide range of language contact phenomena such as creole and mixed language formation, convergence, first language attrition, and second language acquisition. In all these cases, a single universal cognitive principle underlies the seemingly disparate linguistic outcomes.

Myers-Scotton has held positions as professor of linguistics at Yale University, Michigan State University, and the University of South Carolina where she is currently the Carolina Distinguished Professor of Linguistics. She is currently writing a book for Oxford University Press on contact linguistics in which she unifies a vast body of language contact data under her theoretical models. Although her theories are controversial, Myers-Scotton is, more than any other single person, responsible for elevating the level of discourse in the field of contact linguistics by proposing a set of testable universal principles underlying bilingual language production at both the social and the structural level.

Nida, Eugene Albert (1914–)

R. E. Longacre

Nida was born in 1914 in Oklahama City, Oklahoma, USA. He received a BA at the University of California, Los Angeles in 1936, MA in patristics in 1939 at the University of Southern California, and PhD in linguistics in 1943 at the University of Michigan; also numerous honorary degrees and awards from institutions in the USA and other countries. He was Professor of Linguistics at the Summer Institute of Linguistics (which eventually located for many years at the University of Oklahoma) 1937–53.

Nida has had a continuing involvement with agencies interested in the translation of the Christian scriptures. Besides his involvement with the early work of the Summer Institute of Linguistics in Mexico he has been Executive Secretary for Translations, American Bible Society (1943–84), consultant for the United Bible Societies (1947–90), and continues as consultant for the American Bible Society 1984 to the present. In these various capacities he has succeeded in lifting translation concerns from those of a specialist group onto the plane of broad linguistic and cultural concerns.

Nida's early linguistic interests centered around grammar, which in the 1940s and 1950s was conceived of largely as morphology. Both Nida's 1946 *Morphology* and his larger 1949 volume of the same title (both University of Michigan Press, Ann Arbor, MI) reflect shifting currents in American structural linguistics—from the process orientation of Edward Sapir (see *Sapir, Edward*) to the flat morphemes-and-their-allomorphs orientation of Zellig Harris and Bernard Bloch. Nida has never lost his interest in *words*; some of his most mature and recent work has been his exploration of the lexical resources of the Greek New Testament (see below).

Perhaps Nida's greatest contribution lies in the field of translation theory and practice. In his role as a teacher of future linguists and translators as well as in his more global role of consultant for missionary translators his influence has been profound—exceeded perhaps only by the influence exerted by the constant flow of his writings. He has done fieldwork in over 85 countries and in over 200 languages. Nida early came to emphasize dynamic and functional equivalence across languages and cultures as the key to successful translation. As linguistics has evolved during his scholarly life he has interacted with and made his own contributions to such developments as discourse analysis (textlinguistics) and sociolinguistics.

From his early 1947 work *Bible Translation* a steady stream of publication has followed. Running rather to books than articles his production has been of two sorts: (a) such general works as those already mentioned and exemplified in the bibliography; and

(b) special manuals for translators of given books of the Bible (not indicated in the bibliography). The latter have been variously authored, coauthored, and/or edited by Nida, and cover a dozen or so books of the New Testament as well as the book of Ruth. In these manuals Nida has displayed a fine sensitivity to and uncanny prescience of passages where translators of the scriptures are likely to encounter lexical problems, cultural mismatches, syntactic tangles, and problems in textual cohesion and coherence.

Nida's outstanding achievement latterly has been *The Greek Lexicon of the New Testament based on Semantic Domains* (1988). This embodies a new departure in lexicography. Here words of similar semantic domains are so grouped as to give insight into the lexical structure of the Koiné Greek (see also *Koinés*).

Nida has belonged to a number of learned societies which reflect his varied interests. Besides the American Anthropological Association, the Linguistic Society of Canada and the United States, the American Association for Applied Linguistics, and the Society of Biblical Literature, they include the Linguistic Society of America (President 1968) and the Society for Textual Scholarship (President 1987–88).

Paulston, Christina Bratt (1932–)

M. Swain

Christina Bratt Paulston was one of the earliest proponents of the application of principles derived from sociolinguistics to language teaching and to educational linguistics. She was the first to apply Dell Hymes (see *Hymes, Dell Hathaway*), notion of communicative competence to language teaching (Paulston 1974). The focus of her scholarly work proceeded from the teaching of English as a second language (Paulston 1980a) to bilingual education (Paulston 1980b, 1988, 1992) to minorities, language policy, and linguistic rights (Paulston 1994, Paulston and Peckham 1998). She has worked on the history of sociolinguistics and is currently studying the sociolinguistics of ancient Palestine.

Born in Stockholm in 1932, Paulston was educated in classics and modern languages in the gymnasium there. On graduation in 1951, she received a Kellogg Foundation scholarship to study at Carleton College, Minnesota, where she earned a BA in 1953. She went on to receive an MA in English literature at the University of Minnesota. After graduation, she taught English and French for the next five years at high schools in Clara City, Lake Woebegon, and Pine Island, all in Minnesota.

In 1960, while teaching at the American School in Tangier, Morocco, she met Rolland Paulston, her future husband. From 1963 until 1968, the new couple lived, worked, and studied in Sweden, the USA (at Columbia University), India, and Peru, each completing a PhD dissertation. In 1969, Paulston was appointed to the linguistics department at the University of Pittsburgh, where her husband had joined the school of education a year earlier. This has remained their academic home since then.

Paulson was director of the English Language Institute at the University of Pittsburgh from 1969 until 1998, and chair of the department of linguistics from 1974 until 1989. She was active in International TESOL, serving as Second Vice President and Convention Chair in 1972 and President in 1976. From 1976 until 1981 she served as a member of the Board of Trustees of the Center for Applied Linguistics.

During her career, she has published many articles and books in the areas of English as a second language, language teaching, bilingual education, teacher training, and sociolinguistics. More recently, her interests have focused on the sociology of language and gender, and historical sociolinguistics.

Platt, John T.

M. Görlach

John Platt was associate professor of linguistics at Monash University, Clayton, Victoria, Australia, until his untimely death in 1990. Apart from his research and teaching in various disciplines of linguistics, he was one of the leading and most stimulating scholars in the field of English as a world language, into which he brought his keen interest in his native Australian English and near-native English of Singapore and Malaysia. From the 1970s on, John Platt published a long series of articles predominantly on South East Asian Englishes, but mainly on the forms and functions of English in the city-state of Singapore, often collaborating with his wife Heidi Weber and with research students. His sociolinguistic studies of the local varieties are characterized by rigid methodology; and he was quick to see the importance of methodologies from Creolistics for New English Studies (see *New Englishes*; *Pidgins and Creoles: Models*). He was the first to use implicational scaling and to apply the concepts of 'creoloid,' 'basilect,' 'mesolect,' and 'acrolect' to Singapore English. His interest did not stop here: while including studies of literary uses of Singapore English, his research into the functions of English in the polyglot speech community quite naturally led him on to investigations of interlanguage, multilingualism, and inter-ethnic communication. Among the publications that had—and will continue to have—the greatest impact on the study of world English, there are four that should be named. *English in Singapore and Malaysia* (Platt and Weber 1980) is an impressive, exhaustive account of the status, features, and functions of English in the region, which has not been surpassed. Almost simultaneously written, but published two years later, is his contribution on 'English in Singapore, Malaysia, and Hong Kong' in *English as*

a World Language (Bailey and Görlach), which must have informed many readers, whose main interest was not in the area, on the fascinating mosaic of the three regions treated. These descriptions were complemented by the representative corpus of localized texts, which he selected and edited with excellent linguistic annotations: *Singapore and Malaysia* (Platt et al. 1983). Finally, *The New Englishes* (Platt et al. 1984) is an ambitious attempt at a cross-variational account of the similarities of New Englishes on the various levels. The forward-looking ideas in this book have not been taken up by scholars to a sufficient extent, certainly because few would have had John Platt's combination of linguistic competence that would have been indispensable to deal adequately with matters of such great complexity.

Poplack, Shana

G. Van Herk

Shana Poplack was born in Detroit, Michigan. Building on the methodological innovations and minority language focus of William Labov, Shana Poplack has extended the techniques and scope of linguistic variation theory to bilingual speech patterns, comparative reconstruction of ancestral speech varieties, and prescription-praxis dialectic in the coevolution of standard and nonstandard languages.

Her 1979 dissertation (University of Pennsylvania) characterized the reduction rules affecting syllable-final consonants in Puerto Rican Spanish, and introduced a nuanced quantification of Kiparsky's functional hypothesis as it intersects with variable morphological concord. At the same time, Poplack's studies of code-switching among Puerto Ricans in New York introduced the Equivalence and Free Morpheme constraints, universal patterns of switch-points occurring only at nonword-internal sites where word order is shared by two languages, and demonstrated that fluent code-mixing is a bilingual skill rather than a defect (see *Code-switching: Overview*).

In 1981 Poplack moved to the University of Ottawa, where she assembled, transcribed, and concordanced a 'mega-corpus' of conversations among 120 French speakers in the Canadian capital region. Studies of thousands of loanwords and switches in this corpus led her to rephrase the Free Morpheme constraint in terms of the ubiquitous process of 'nonce' borrowing, and to quantify the discourse conditions on code-switching. Over two decades, Poplack has broadened and deepened her theory of bilingual syntax in social context, and has quantitatively confirmed the predominance of nonce borrowing and equivalence-point code-switching in a range of similarly constructed bilingual corpora of typologically different language pairs.

Poplack's two wide-ranging volumes on the origins of African American Vernacular are based on evidence from elderly descendants of American slaves recorded during fieldwork in isolated communities in the Samaná peninsula (Dominican Republic) and in Nova Scotia. In these volumes, variationist analysis of Early African American English reveals widespread retention of syntactic and morphological features (including the entire tense and aspect system) from earlier British and colonial English, contrary to previous theories attributing such features to a widespread American creole.

Poplack's analyses of vernacular varieties of Spanish, French, and English are characterized by skepticism towards standard explanations of variation and change based on language simplification or external influences, in favor of historical and com-parative studies of internal evolution. This is most evident in her analyses of tense, aspect, and mood in French. In work involving large-scale multivariate analysis and systematic critical investigation of early prescriptive grammars, Poplack showed that loss of the subjunctive, advance of the periphrastic future, and the preference for conditional concord can all be traced to earlier stages of French, rather than to post-settlement contacts with English, and thus do not represent linguistic degradation.

Quirk, Professor Sir (Charles) Randolph (1920–)

J. Roberts

When Randolph Quirk, then Professor of English Language in the University of Durham, announced his plans for a survey of British English in 1959 he cannot have foreseen the central position his work

901

would come to occupy in language studies. At a time when linguistic theorists chose to appeal to intuition for judgment in usage, his scheme seemed particularly adventurous in its aim to draw together representative samples of a wide range of spoken and written materials. Within a few years other computerized collections were to be initiated, but the ambitions of data based surveys of usage for the latter part of the twentieth century were essentially established with the initiation of what was to become the Survey of English Usage (SEU). This uniquely combined 'corpus' study with psycholinguistic elicitation techniques, reaching beyond the corpus. Quirk was Director of the Survey, based in University College London, until 1981. He continued to play a major role in its activities during his years as Vice-Chancellor of the University of London (1981–85) and as President of the British Academy (1985–89), and he remains a central figure in the project's researches. His outstanding abilities both in scholarship and administration have ensured showers of honorary degrees, fellowships, and consultative positions. His generosity as teacher and colleague is evidenced by many fruitful collaborations over the years on innumerable books and articles, not least with Greenbaum, Leech and Svartvik on the magisterial *A Grammar of Contemporary English* (1972) and its successor *A Comprehensive Grammar of the English Language*, which was first published in 1985 but has been continually revised and updated.

Charles Randolph Quirk was born on July 12, 1920, son of the late Thomas and Amy Randolph Quirk, Lambfell, Isle of Man. After education at the Cronk y Voddy and Douglas High Schools, his undergraduate years were interrupted by service in the RAF (1940–45), and he supported himself by playing regularly in a danceband. A lectureship in English at University College London (1947–54) followed quickly upon graduation, a period broken only by a year (1951–52) as Commonwealth Fund Fellow in Yale University and the University of Michigan. During his years at Durham, first as Reader (1954–58) and afterwards as Professor (1958–60), he was still best known as a medievalist, writing articles and monographs mainly on Old and Middle English and Old Norse. His subsequent work on the structure of present-day English has always therefore been grounded upon a deep knowledge of historical scholarship. This can be seen very clearly in *The Use of English* (1962, enlarged edition 1968), a widely read book that grew out of popular talks given on the BBC World Service, and in its long-needed successor, *English in Use* (1990, with G. Stein). Although many of his publications are concerned with the technicalities of

grammar, he could never be categorized as a prescriptive grammarian, despite the respect accorded his authority by those who consult his writings. Rather he shows a lively concern for what is 'appropriate language,' a phrase used by him in discussion of Dickens (inaugural lecture given in Durham, 1959), and he has communicated this concern in many lively lecturers, papers, and reviews. Some flavor of these can be gained from such collections as *The Linguist and the English Language* (1974) and *Words at Work: Lectures on Textual Structure* (1986).

Randolph Quirk first married Jean Williams (1946, marriage dissolved 1979) and has two sons. In 1984 he married Gabriele Stein, professor of English in the University of Heidelberg, with whom he has collaborated in several publications. He travels widely, often for the British Council, on whose Board he served between (1983–91). In the UK, as well as abroad, his is an important voice in deliberations on all aspects of the teaching of English, for example, EFL, speech therapy, and the teaching of Standard English in the National Curriculum.

Reinecke, John E. (1904–82)
G. G. Gilbert

Reinecke was born in Kansas, and died in Honolulu, Hawaii. He received his BA in education from Kansas State Teachers' College in 1925, moved to Hawaii in 1926, and taught at various high schools on the Big Island in 1926–35. In 1932, he married Aiko Tokimasa, with whom he collaborated in studies of Hawaiian Creole English and in the labor movement. He moved to Connecticut in 1935. He received his PhD from Yale University in race relations in 1937, and traveled in the southeastern USA. He was appointed assistant professor of sociology at the University of Hawaii 1937–38, but was not reappointed because of his liberal political views and active involvement on behalf of the labor movement. Reinecke taught at various high schools on Oahu during 1939–48. He was dismissed with revocation of his teaching certificate, because of his political views and vigorous defense of the labor movement in his writings and actions. In 1951 he was reduced to selling the local newspaper, and arrested by the FBI in August 1951 and charged with violating the Smith Act. In June 1953, he and six others ('the Hawaii Seven') were found guilty of all charges and sentenced to five years in prison and fined $5000. While the case was on appeal, he was employed as a researcher and labor negotiator by Unity House in Honolulu (1958–68). His conviction was overturned by the Ninth Circuit Court of Appeals in San Francisco in 1958. In the mid-1960s, encouraged by Stanley Tsuzaki of the University of Hawaii, he returned to the study of the sociolinguistics of pidgin/creole languages. His teaching certificate was restored in 1976 by the Hawaii State Board of Education and he was exonerated from all charges. In 1978, by special act of the Hawaii legislature, an out-of-court settlement of $250,000 was paid to Reinecke and his wife for the violation of their constitutional rights.

During his 'first' sociolinguistic period, both his MA thesis of 1935 and his dissertation of 1937 represent remarkable pieces of work. Reinecke was one of the pioneers in founding the sociology of language as a border discipline between sociology and linguistics, and was the first researcher to apply these new insights to the sociology/linguistics of pidgin/creole languages. The 1937 dissertation is still eminently worthy of publication, with annotations. Until comprehensive surveys of pidgin and creole languages and linguistics half a century later to some extent superseded it, it was regarded as the most comprehensive and ambitious work even attempted in the pidgin/creole field.

Reinecke's 'second' sociolinguistic period, from about 1965 to his death in 1982, resulted in the belated publication of his thesis, the compilation (with four collaborators) of the impressive annotated bibliography of pidgin/creole languages, and the founding and six-year editorship of the general newsletter of the field, the *Carrier Pidgin*.

He was a charismatic figure, on the Islands and elsewhere, a force to be reckoned with in the labor movement, the cultural history of Hawaii, the sociology of language, and pidgin/creole linguistics. 'John Reinecke embodied a rare combination of qualities: humanism, scholarship, and activism. The very act of studying pidgin and creole languages constitutes a form of social protest against the injustice done to their speakers. Hence, his work on behalf of the labor movement was not the only form of activism that he supported. Creole language study was the other horse pulling the cart. [For him,] labor and linguistics were thus complementary' (Gilbert 1987: ix).

Rickford, John Russell
J. Baugh

John R. Rickford began his distinguished sociolinguistic career at the University of California at Santa Cruz, where he graduated with highest honors in 1971. He then attended the University of Pennsylvania, receiving a PhD in linguistics in 1979. Long before completing his doctoral dissertation, Rickford began to explore the historical and linguistic correlation between African American vernacular English (AAVE) and English/African-based Creoles that resided throughout North America and South America.

Early examples of his keen linguistic insight can be found in his 1975 paper, titled 'Carrying the new wave into syntax: the case of Black English BIN,' or 'The question of prior creolization in Black English' (1977). These studies, and others, defy simplistic classification of Rickford as a Creolist, sociolinguist, humanist, or educator. His scholarship, like that of his mentors William Labov and Dell Hymes, represents an array of seminal contributions that simultaneously offer precise individual discoveries at the same time that they advance general sociolinguistic principles. For example, *A Festival of Guyanese Words* (1978) offers linguistic insights into a specific speech community at the same time that it establishes firm sociolinguistic principles for data collection, interviewing, and ensuing analyses.

Rickford first developed his linguistic interest in his native Guyana, where he was born on September 16, 1949. He mingled with cane-cutters and scholars alike, noting differences in language, culture, and social opportunity. His professional resolve to bridge linguistic science with educational application was most visible during the 1997 US Ebonics controversy (see *Ebonics and African American Vernacular English*). Spawned by that controversy, he penned *Suite for Ebony and Phonics* (1997) followed thereafter by *Spoken Soul: The Story of Black English* (2000), coauthored with his son—Russell John Rickford—and winner of the exalted American Book Award. These achievements have not only advanced our collective knowledge of African American language, they hint at Rickford's broader concerns for other linguistically disenfranchised populations throughout the world.

In 1980, after teaching briefly at the University of Guyana, Rickford joined the linguistics department at Stanford University, where he continued in the footsteps of luminaries like Charles Ferguson and Joseph Greenberg, particularly regarding the empirical orientation of their collective studies of language in social context. Along with his wife, Angela Rickford, who is Professor of Education at San Jose State University, he continues to pursue advanced literacy and educational opportunities for African American students. More significantly, he does so based upon consistent and extensive sociolinguistic studies in African American communities, often through strategic collaborations with his former students and colleagues.

Another hallmark of Rickford's illustrious career is reflected by his esteem at Stanford University, where he is director of the Center for African and Afro-American Studies, serving as the Martin Luther King Jr. Centennial Professor. Through that assignment, and others as President of the Society for Pidgin and Creole Languages, he has helped to shape the future course of scientific studies of contact vernaculars, their stylistic diversity and heritage, and the educational consequences of these linguistic facts.

Rickford's collaborations and collaborators are equally noteworthy. With Suzanne Romaine he has edited *Creole Genesis, Attitudes and Discourse: Studies Celebrating Charlene Sato* (1999), while with Penelope Eckert he has edited *Style and Sociolinguistic Variation* (2001), and his forthcoming edition in collaboration with Edward Finegan is titled, *Language in the USA 2000* (in press). These substantial collaborations far exceed the speakers of African descendant that captured Rickford's attention as a young African American scholar. Unlike many American sociolinguists, whose lives were frequently shaped by the confines of American culture (diverse though that may be), Rickford is a true citizen of the world. He grew up in Guyana, and went on to be educated at London University. That global exposure and his devotion to the advancement of greater social opportunities for those who are linguistically disenfranchised represents applied linguistics at its finest.

Romaine, Suzanne (1951–)

C. M. Sangster

Suzanne Romaine has made significant contributions to many different fields of linguistics, as a writer, editor and teacher, and, most of all, as a researcher. Both her work and her reputation can truly be said to be international. Her most important work is in the area of sociolinguistics, although she also has interests in historical linguistics. Her sociolinguistic research incorporates the areas of multilingualism, linguistic diversity, language change, language acquisition, and language contact. Romaine's other areas of interest include language and gender, corpus linguistics, pidgin and creole languages, bilingualism, and endangered languages.

Born in Massachusetts, USA, she was educated at Bryn Mawr College in Pennsylvania, where she studied German and Linguistics. After this, her graduate work was carried out in the UK, first at the University of Edinburgh, Scotland and then at the University of Birmingham, England, from which institution she received her PhD, which was about the methodology and status of sociohistorical linguistics, in 1981. After spending three years in Nijmegen, The Netherlands as a senior research scientist in Linguistic Anthropology at the Max Planck Institute for Psycholinguistics, and also as a lecturer in Linguistics at Birmingham, Romaine was appointed Merton Professor of English Language at the University of Oxford in 1984; a post she still holds.

Visiting scholarships and professorships have taken her to Toronto, Canada, and Uppsala, Sweden, and her fieldwork has been conducted on a global scale. Her work on bilingualism focused on the behavior of Punjabi speakers living in England. She has studied the language of children and adolescents both in Scotland and in Papua New Guinea and, more recently, she has worked extensively in Hawaii.

Romaine is the author of several important books; a selective bibliography is below. Her books have been translated into Italian, Spanish, and Japanese, and range from introductory textbooks such as *Language in Society* (2000), to her authoritative book *Bilingualism* (1995) to more advanced works; most recently her critically-acclaimed analysis of the loss of linguistic diversity through language death, *Vanishing Voices* (2000). She was also the editor for volume 4 (1776–1997) of the *Cambridge History of the English Language*. She continues to teach on a wide range of sociolinguistic and interdisciplinary themes and to carry out international research.

Sacks, Harvey (1935–75)

G. Psathas

Sacks was an original scholar, a profound genius whose thought spanned traditional disciplines and founded a new one, conversation analysis, thereby contributing to the systematic study of language in

interaction. His efforts were oriented to the study of the organization or orderliness of language use. The sociological, linguistic, and philosophical foundations of his thought are rooted in those whose work he studied or worked with: Garfinkel and ethnomethodology, Erving Goffman and interaction analysis (see *Goffman, Erving*), Chomskyan linguistics, and Wittgenstein's ordinary language philosophy.

Sacks earned his doctorate in sociology at the University of California, Berkeley, USA (1966) an LLB at Yale Law School (1959), and a BA at Columbia College (1955). For a period of approximately 11 years, 1964–75, he lectured at the University of California, Los Angeles and Irvine. His lectures were recorded, transcribed, and then duplicated and made available to those who requested them. The tapes were not saved. His colleagues and collaborators, primarily Gail Jefferson and Emanuel Schegloff, have since been responsible for editing and preparing his lectures for publication. Sack's lectures achieved a worldwide circulation during his lifetime and since their collection and publication in 1992, have continued to influence many scholars and researchers in sociology, communication studies, and sociolinguistics.

In these and other publications, he treated such topics as: the organization of person-reference; adjacency-pairs; topic organization in conversation; pronouns as transformational operations in conversation; speaker selection preferences; sequential tyings; the presequence; preference for recipient-design or 'orientation to coparticipant' in talk; 'pro'-verbs and performatives in conversation; the organization of turn-taking; turn-allocation constraints on turn-construction; conversational openings and closings; and puns, jokes, stories, and repairs in conversation.

Two volumes now contain the bulk of his lectures (Sacks 1992). He never published a book during his lifetime, though he had planned one and had written an introduction to it.

Sankoff, Gillian (1943–)

C. Surek-Clark

Gillian Sankoff's contribution to sociolinguistics focuses on languages in contact using a multidisciplinary approach drawing from Linguistics, Anthropology, and Sociology. Her work advances our knowledge of the interrelationship between language and society, with special emphasis on Austronesian languages, pidgins and creoles, bilingualism, and Canadian French.

Born to English-speaking parents in Montreal, Canada, Sankoff received her academic degrees from McGill University culminating in a PhD thesis in Anthropology in 1968 titled *Social aspects of*

multilingualism in New Guinea. From 1968 to 1978 she was an Assistant-Associate Professor in the Department of Anthropology at the French-speaking Université de Montréal. In the early 1970s, Sankoff held a visiting professor post in the Anthropology Department at the University of California, Berkeley, and in the summer of 1973 she was a visiting Associate Professor at the Linguistics Institute held at the University of Michigan. During 1975 Sankoff was a Fellow at the Center for Advanced Study in the Behavioral Sciences at Palo Alto, where several of her most important contributions to the field were written. In 1981 she joined the Department of Linguistics at the University of Pennsylvania where, together with William Labov, she has trained a generation of sociolinguists. A true international scholar, Sankoff has taught and carried out research in Canada, Brazil, and France lecturing in English, French, and Portuguese.

Sankoff's most important contributions to date occurred during a period of time when Chomsky's approach to language as a product of the mind strongly shaped the discipline. Her 1980 book titled *The Social Life of Language* examines the transition 'towards a view that language is structurally stamped by the fact of its use in social life' (p. xviii). Sankoff's career focuses on two communities, one situated across an ocean, and the other across an ethnic boundary in her hometown of Montreal. In the latter, she studies French–English bilingualism among the French-speaking minority population, and throughout her career she has contributed substantially to a longitudinal study carried out in collaboration with colleagues from the Université de Montréal. Working among the Buang speakers of Papua New Guinea at the beginning of her career, she was present during the transition phase in which the pidgin Tok Pisin attained the status of a national language. Sankoff observed the pidgin acquire native speakers as its creolized form emerged, shedding light on categorization and social use of language in a non-Western culture.

Most recently, Sankoff's interest focuses on language change across the lifespan of individual speakers in the Montreal population, and concurrently she is working on a book examining the evolution of New Guinea Tok Pisin over the past 100 years.

More than any other scholar of language in her generation, Gillian Sankoff is an innovator. Through her multidisciplinary work encompassing anthropology, quantitative sociolinguistics, ethnography of speaking, pidgins and creoles, and language policy she continues to illuminate important aspects of sociolinguistics.

Sapir, Edward (1884–1939)
R. Darnell

Edward Sapir, unquestionably the most distinguished student of Native American languages trained by Franz Boas (see *Boas, Franz*) and cofounder with Leonard Bloomfield of an autonomous discipline of linguistics in the USA, distinguished himself in such diverse fields of anthropology as linguistics, sociolinguistics, ethnology, folklore, and culture-and-personality; he wrote poetry and literary reviews and composed music. He remains the exemplary proponent of the humanistic roots of anthropology and linguistics as well as of the inseparability of their subject matters and points of view.

Sapir was born in Lauenberg, Pomerania on January 26, 1884. His parents, Eva Siegel and Jacob David Sapir, a Jewish cantor, emigrated to New York City in 1889. While still in high school, he won a prestigious Pulitzer scholarship to Columbia University. He received a BA in 1904 and an MA in 1905 in Germanic philology. His PhD in 1909 was in anthropology and reflected the program of urgent ethnology and linguistics of Franz Boas. Sapir was the only one of Boas's students to specialize in linguistics and rapidly came to set the standards for linguistic description and theory for all of Boasian anthropology, including the work of his former teacher and mentor.

Sapir held research fellowships at the University of California in 1907–08 and at the University of Pennsylvania in 1908–10, and headed the new Division of Anthropology of the Geological Survey of Canada from 1910–25. He taught at the University of Chicago from 1925–31 and at Yale University from 1931 until his premature death on February 4, 1939.

His major linguistic fieldwork was with Wishram Chinook (1905), Takelma and Chasta Costa (1906), Yana (1907–08, 1915), Ute (1909), Southern Paiute (1910), Nootka (1910, 1913–14), Sarcee (1922), Kutchin and Ingalik (1923), Hupa (1927), and Navajo (1929). He attempted to follow the Boasian ideal of a grammar, texts, and a dictionary for each language studied. As early as 1911, in relation to the publication of his extensive grammar of Takelma in the *Handbook of American Indian Languages*, Sapir challenged the standards for linguistic description in aboriginal America set by Boas so as to include work by individuals without professional training. This was, in retrospect, Sapir's first move toward the separation of North American linguistics from its basis in anthropology and the study of the American Indian.

In 1921, Sapir published *Language: An Introduction to the Study of Speech*, which was geared to the educated layman. It remains a classic for its citation of non-Indo-European languages, appreciation of the relationship between language and culture, inclusion of humanities perspectives on language, and insistence on the beauty and elegance of linguistic form.

Independently of parallel developments in Europe, Sapir developed the concept of the phoneme, emphasizing the psychological reality of sounds for the speakers of a language. He moved toward morphophonemics, pioneered in the study of English semantics, emphasized a process model for the writing of grammar, dabbled in the construction of an international language, and returned at the end of his life to Indo-European philology with reference to the definition of the circum-Mediterranean cultural and linguistic area.

Much of his later work moved away from linguistics in the narrow sense. After his appointment at the University of Chicago in 1925, Sapir rapidly became the anthropological spokesman for the interdisciplinary social science emerging around the Chicago School of Sociology in the 1930s, particularly through his collaboration with interactional psychoanalyst Harry Stack Sullivan and political scientist Harold D. Lasswell. Sapir's theoretical writing in the period after his Rockefeller Foundation-funded move to Yale in 1931 emphasized the impact of culture on the development of personality and the creative role of the individual in culture. His Yale student, Benjamin Lee Whorf, developed Sapir's ideas about the relationship of language and culture (see also *Sapir–Whorf Hypothesis*).

Sapir's years at Yale were not entirely happy ones. He was particularly plagued by anti-Semitism and ill-health. At Chicago and Yale, however, Sapir trained a coterie of American Indian linguists. Among his most distinguished linguistic students were F. K. Li, Morris Swadesh, Stanley Newman, Mary Haas, George Trager, Benjamin Whorf (see *Whorf, Benjamin Lee*), Zellig Harris, and Charles Hockett. Sapir was a cofounder of the Linguistic Society of America in 1925 and taught at its Linguistic Institute in 1937.

Saville-Troike, Muriel
R. Pandharipande

As a distinguished scholar, educator, and a humanist, Muriel Saville-Troike occupies a unique position in the field of sociolinguistics. She is one of the early researchers spearheaded by Hymes (see *Hymes, Dell Hathaway*) who challenged the established paradigm of linguistic theory, which treated language as an autonomous system. In her highly acclaimed book, *The Ethnography of Communication* (1982), Saville-Troike argued for the need to include the hitherto neglected interactive and communicative functions in the theory of language. She demonstrated that the explanation for why communities differ in ways of speaking (language use), is rooted in their ethnographic make-up, i.e., in their beliefs, values, norms, and attitudes. The object of sociolinguistic investigation and description, she argued, should be the relationship between the ethnographic profiles and the linguistic structures characteristic of different speech communities. Her research provided the foundational framework for the now dominant, interdisciplinary model of language analysis in sociolinguistics called 'Ethnography of Communication' (see *Ethnography of Speaking*).

Above all, Saville-Troike is widely recognized as a humanist who has become a spokesman for the disadvantaged bilingual children of the American

Indians (Navajo and Apache) and Latinos, and has argued that their failure in the bilingual education programs was not because of their deficient potential, but rather due to the curriculum, teachers' training program, and testing methods which ignored the cultural background of the bilingual children. Likewise the alleged deficiency in the English of immigrant Spanish and Chinese children had to be evaluated in terms of the less than acceptable curriculum which was insensitive to the children's cultural background. Saville-Troike argued for the need to recognize variation in second language acquisition as a tool to reconstruct the linguistic and cultural background of the second language learner. Her most influential work in this area has been her book, *Foundations for Teaching English as a Second Language* (1976) and several subsequent textbooks and monographs, which clearly articulate the role of culture in second language acquisition.

Saville-Troike has presented a clear blueprint of the methods needed to incorporate the cultural component of the second language learner into the bilingual curriculum (*Curriculum Guide for Teachers of English in Kindergartens for Navajo Children*, and several other texts and monographs). Her bold argument for change in classroom teaching, the nature of proficiency testing, and teacher education to include the cultural component as a necessary ingredient of language learning/teaching has made her an highly influential leader in the field of bilingual education. Moreover, she actively implemented these programs through a number of administrative positions, which she has held throughout her career.

Schegloff, Emanuel (1937–)
J. Heritage

Emanuel Schegloff is the co-originator, with the late Harvey Sacks (see *Sacks, Harvey*) and Gail Jefferson, and the leading contemporary authority of the field which has come to be known as 'conversation analysis' (CA). Educated at Harvard (BA 1958) and University of California, Berkeley (PhD 1967), Schegloff was the author of the field's first publication, 'Sequencing in conversational openings' (1968). Since that time he has published upwards of 60 research papers that have established many of the major concepts and findings that are now treated as axiomatic in the field. Schegloff has developed the field of CA through a series of fine-grained empirical studies of the details of interactional conduct. These studies have shown the truly remarkable degree to which social organization—a 'syntax' of action—inhabits the practices and behaviors that make up human social interaction. They constitute an extended demonstration of how the empirical details of human interactional conduct can be brought under precise analytic control, and have served as an inspiration to the specialty which he cofounded.

Schegloff's development of CA has involved a major reconceptualization of extant perspectives on the nature of language and social interaction, of the kinds of data which are relevant and appropriate for the study of language, and of the analytic procedures through which empirical investigation may best be forwarded. This reconceptualization is based on the recognition that social interaction is, as Schegloff puts it, 'the primordial site of human sociality,' and that the demands of social interaction are central in shaping the development and use of language. At the same time it embodies the recognition that the sociological study of interaction cannot be developed as a coherent discipline without detailed attention to the ways in which the properties of language are systematically exploited in the execution of interactional tasks.

Schegloff's papers have identified major structural axes of interaction including turn-taking (Sacks, Schegloff and Jefferson 1974), sequence organization (Schegloff 1995), repair (Schegloff, Jefferson and Sacks 1977), and turn organization (Schegloff 1996). Each of these papers establishes a domain of study by identifying fundamental choices that participants in conversation must make, and isolating elements of the functional architecture through which they are implemented. While none of these papers is intended to be definitive, and most of these areas have undergone extensive expansion over the years (whether in the form of progressive internal refinements in the empirical territory staked out, or through wholesale additions to it), the basic

909

frameworks that were developed in the initial papers, as much as thirty years ago, have remained remarkably intact.

Schegloff's research has repeatedly and painstakingly demonstrated that behind the 'implacable familiarity' of everyday actions lie fascinating and exact orders of organization of great generality and scope. Again and again Schegloff has shown that, in social interaction, it is order rather than chaos that is the norm; precise, specific order; order that the participants use and rely on to achieve their interactional objectives. Above all, almost every paper he has written underwrites the notion that because 'language is the vehicle for living real lives,' the primary research site for CA must be the 'real life' of ordinary conversational interaction.

In the last analysis, CA constitutes the most sustained attempt yet mounted to build a natural history of human interaction; a natural history variously inflected by culture, but likely to embody a substantial mass of commonality in human inter-actional practices, and possibly a good measure of universality.

Schiffrin, Deborah (1951–)

S. Hunt

Deborah Schiffrin is best known for her work in discourse analysis, especially interactional sociolinguistics, and, in particular, for her two books *Discourse Markers* (1987) and *Approaches to Discourse* (1994).

She received her BA and MA from Temple University, USA, in sociology. An interest in Erving Goffman's work on face-to-face interaction and, more generally, in semiotics and sociological/linguistic theory, prompted her shift to sociolinguistics. Schiffrin was awarded a PhD in linguistics from the University of Pennsylvania in 1982 for her dissertation entitled *Discourse Markers*, an analysis of interviews with seven Jewish residents of a Philadelphia neighborhood. This work was supervised by variation analyst William Labov and was later published in book form. *Discourse Markers* (1987) focuses on the use of coherence markers: the connectives *and, but, or*; the causal markers *so, because*; the temporal markers *now, then*; *well*, a marker of response; *oh*, a marker of information management; and markers of information and participation *y'know* and *I mean*.

In 1982 she was appointed to the teaching staff of the Linguistics Department at Georgetown University where she has remained to the present day. During this time she has published prolifically in discourse analysis and sociolinguistics. Her publications reflect her continuing interest in discourse markers and narrative, and include a significant number of articles which provide overviews of *discourse* analysis, *interactional sociolinguistics, conversation analysis*, and *pragmatics*. The *Handbook of Discourse Analysis* (forthcoming), with coauthors Tannen and Hamilton, continues this trend. Schiffrin is currently on the editorial boards of *Language in Society, Journal of Pragmatics, Language and Communication, Linguistic Variation and Change*, and *Discourse Studies*. She has edited books with Deborah Tannen, John Baugh and Ralph Fasold, amongst others, on topics spanning discourse analysis and language variation and change.

Approaches to Discourse (1994) provides a useful introduction to six different approaches to the analysis of discourse, focusing on the central scholars of each approach: *Speech Act Theory* (Austin and Searle); *Interactional Sociolinguistics* (Gumperz and Goffman); *Ethnography of Communication* (Hymes); *Pragmatics* (Grice); *Conversation Analysis* (Garfinkel, Sacks, Schegloff and Jefferson); and *Language Variation* theory (Labov). The first three approaches are used to analyze question–answer sequences and the remaining three to explore referring expressions, particularly existential *there is*, in an attempt to show how different approaches would bring different insights to these core concerns of discourse analysis.

More recently, Schiffrin's work has focused on Holocaust survivors' life stories and public discourse about the Holocaust in general. Her forthcoming book, *Language, Text, and Interaction* is a collection of previously published and new articles, the latter being on the discourse pragmatics of referring terms and information structure.

Schuchardt, Hugo (1842–1927)

G. G. Gilbert

Schuchardt was born in Gotha, Germany, and died in Graz, Austria. His father was a jurist (*Staatsassessor*) in Gotha; his mother, of noble extraction, was from a family closely connected with the court of the Duke of Sachsen Gotha-Altenburg. Schuchardt studied under Diez at Bonn was *privatdozent* at Leipzig (1870), and professor at Halle (1873) and at Graz (1876–1900). A man of independent means, he remained in retirement in Graz for the last 27 years of his life, choosing to stay in the isolated southern Austrian city rather than to return to his native Germany. By all appearances, he was a hypochondriac, believing he was suffering from neurasthenia—but nevertheless living into his eighties. He never married. His house, the Villa Malvina (named after his mother), was bequeathed to the university and subsequently became the home of the Department of Romance Languages. His papers, still largely uncataloged, form an important collection in the rare book section of the university library.

Schuchardt was the first professional linguist to turn serious and detailed attention of a general and comparative nature to the topic of pidgin and creole languages as a typological genre within linguistics. Accordingly, many consider him the father of creolistics. Throughout much of his long life, he was keenly interested in geography, anthropology, and travel descriptions of all kinds. Because of real or imagined problems with his health, and his general disinclination to undergo the rigors of travel outside Europe, he was destined never to see those creole areas he studied so passionately, and was thus denied the opportunity to experience the 'trade and slave languages' at firsthand. Instead, starting about 1880, he came to rely

> on a vast network of correspondents who relayed texts and sociological background information to him in Graz. The correspondents ranged from trained professional ethnologists and linguists, to missionaries, diplomats, military men, adventurers, and travellers generally.
>
> (Gilbert 1980: 4)

The 1880s saw the publication of the bulk of his work on creoles, above all the *Kreolische Studien*, in nine parts, dealing with 'Kreolisch' in its Portuguese, French, or English guise. An insightful manuscript, the tenth creole study 'On the Negro English of West Africa' discovered among his papers in 1983 (Gilbert 1985), was found to anticipate the creole-origin hypothesis of the genesis and development of US Black English, as it was formulated a half-century later by Melville Herskovits, T. Earl Pardoe, John Reinecke (see *Reinecke, John*), and Lorenzo Dow Turner, working independently. Early in his career, Schuchardt was inclined not to go along with the extreme universalist position (as represented, for example, by the Portuguese Creolist, Adolpho Coelho) that universal psychological or physiological laws were at work in the formation of creole languages. He tried to account for them on a case by case basis, citing substrate influences, common (chiefly societal) conditions of development, and so forth.

> Nevertheless, time and again he was struck by grammatical similarities in geographically widely separated pidgins and creoles, especially in the verb system.
>
> (Gilbert 1980: 7)

In the first 15 years of the twentieth century, two additional and highly insightful works on creole appeared: a detailed description of all that was then known about the Lingua Franca (1909) and an important essay (1914) modestly entitled '*Vorbericht*' ('*Preface*') introducing his edition (the first ever published) of C. L. Schumann's (1778) *Saramaccan Dictionary* and other texts. In these works, Schuchardt shows the increasing influence of Wilhelm von Humboldt on his thinking, especially the notion of inner and outer form. Language simplification by

911

individuals or by speech communities is now seen to involve the automatic stripping away of the superficial to arrive at the essential, the inner form. The increased emphasis on psychological processes in the last years of Schuchardt's life indicates the narrowing of the gap between him and Coelho's speculations of the 1880s, on the one hand, and—on the other hand—Bickerton's Language Bioprogram Hypothesis (see *Bickerton, Derek*); which lay 65 years in the future.

Shuy, Roger W. (1931–)

J. Kreeft Peyton

Roger W. Shuy is a pioneer in the field of sociolinguistics. His career exemplifies the highest ideals in applying linguistic knowledge to real-world issues. No one in the field of sociolinguistics (and its related field, applied linguistics) can claim a broader, more penetrating scope of inquiry and influence. Shuy has made important contributions in the fields of dialect variation, discourse analysis, education, law, literature, and medical communication, and has influenced the work of many others in these areas.

Shuy's interest in, and sensitivity to, language issues began when he was very young and growing up in Acron, Ohio. His father had a speech problem that made him difficult to understand, and as a child, Shuy often interpreted for him in conversations with others. Throughout high school and college, Shuy worked in a grocery warehouse, and while studying for a Master's degree in English at Kent State University, he worked at Firestone Tire and Rubber at night. In both of these jobs he was fascinated by the differences between his 'college boy' speech and that of his fellow workers, and he wrote an article for *American Speech* (1964) on 'Tireworker Terms.' His developing interest in dialect variation eventually led him to study with Raven I. McDavid, Jr., a leading dialectologist, and later to a number of groundbreaking studies of English dialects in Detroit and Washington, DC.

Shuy's influence in educational linguistics is profound, from the Detroit Dialect Study and the deficit/difference debates of the 1960s to the Ebonics controversy of the 1990s. He is not only a leader in public discussions of the educational implications of dialect diversity, but has also been a trailblazer in implementing practical programs for educators. In the early days of social dialectology in the 1960s, his application of linguistic knowledge to social and educational problems helped launch a national awareness about dialect diversity in the classroom. He crafted the first models for in-service programs around the country, including the workshops for teachers ordered by Judge Joiner in the celebrated Ann Arbor case (regarding instruction of speakers of African American dialect–see *Ebonics and African American Vernacular English*).

His creative research on language and the medical profession in the 1970s opened up an entirely new field of inquiry with respect to professional–client relationships. His research on language and law over the past couple of decades has led to the development of the field of forensic linguistics (see *Forensic Phonetics and Sociolinguistics*) and, more recently, to research on patients' views of the medical care they receive in the last days of their lives and to changes in provision of end-of-life medical care.

Roger Shuy has also played a prominent role in the institutional development of applied linguistics. He was largely responsible for developing the Research Division at the Center for Applied Linguistics, in Washington, DC, heading major studies on dialect diversity, classroom language, and language attitudes. He directed the first university-based sociolinguistics program in the United States at Georgetown University under a National Science Foundation grant. Over the past three decades, this program has fostered the careers of some of the most

prominent sociolinguistic scholars in the field. He was also one of the initial group of people who conceived of the American Association for Applied Linguistics (AAAL), and he was a strong leader in its early development, serving as the second president in 1979.

Along with his professional and institutional roles, Shuy has had an indelible personal influence on the lives of his colleagues, students, and friends.

Spolsky, Bernard (1932–)
R. Mesthrie

Born in New Zealand, Bernard Spolsky was educated at Wellington College and earned a BA and an MA in English from Victoria University. After a spell of high school teaching in New Zealand (where his bilingual Maori pupils set him thinking about a topic that is still central to his research), he taught at high schools in Australia and England before moving, in 1958, to Israel. In Israel, he spent a year in the army supervising foreign language teaching and two years at the Hebrew University teaching English. In 1961, he became Assistant Professor of Education at McGill University, and in 1964, having completed a PhD in Linguistics from the University of Montreal, was appointed Assistant Professor of Linguistics at Indiana University. In 1968, he moved to the University of New Mexico, where he was Professor of Linguistics, Anthropology and Elementary Education, Dean of the Graduate School, and director of the Navajo Reading Study. In 1980, he returned to Israel, being appointed Professor of English at Bar Ilan University, where he also served terms as head of the English Department and Dean of the Faculty of Humanities.

He has conducted and published research in language testing, second language learning, computers in the humanities, applied linguistics, sociolinguistics, and language policy. His first work in sociolinguistics were studies in Navajo, including Navajo language maintenance, literacy in the vernacular, and lexical borrowing. To these, he added interests in language maintenance and shift, and more recently, language policy. Spolsky's most important work is in the field of Educational Linguistics, especially in language education in multilingual settings. His book *Conditions for Second Language Learning* (1989) set out the requirements for a general theory of second language learning. It is a detailed account of 74 'conditions' (a series of typical and categorical rules or statements) covering the prerequisites for successful learning/acquisition in a variety of situations. Spolsky has published extensively, including 11 other books and numerous articles. He is the editor of *The Concise Encyclopaedia of Educational Linguistics* and a founding editor (together with Elana Shohamy) of the new journal *Language Policy*, whose first issue is due in 2002.

In professional service, he has been President of TESOL, Secretary of the American Association of Applied Linguistics, President of the Israeli Association of Applied Linguistics, Chair of the Board of Trustees of the Center for Applied Linguistics, and President of the International Language Testing Association. He has held a Guggenheim fellowship and a Mellon fellowship, and has been Adjunct Fellow and Senior Research Fellow at the National Foreign Language Center in Washington. Spolsky was honored by a festschrift in 2000 (Cooper et al. 2000).

Srivastava, Ravindra Nath (1936–92)

R. K. Agnihotri

Ravindra Nath Srivastava was perhaps the only Indian linguist who was trained in both the North American and Russian traditions. Though his basic interest was in the theory of language, he constantly kept in touch with empirical issues, particularly the ones that affected the underprivileged masses and minorities. He is remembered across the world for a variety of reasons. He made significant contributions in the areas of experimental phonetics, generative phonology, lexicography, applied linguistics, literacy, stylistics, translation studies, and sociolinguistics. He was an excellent teacher who taught with great dedication, clarity, and precision and whose classes students always looked forward to. He was a skillful team leader who headed several projects and departments with remarkable success, and finally, he was an extremely warm and affectionate person.

Srivastava was born in Ballia, Uttar Pradesh (North India) on July 9, 1936. He received his Master's degree in Hindi literature from Benares Hindu University, Varanasi, in 1957. Even though he subsequently earned a degree in Law, he found his real vocation when he did his Master's (1962) and PhD degrees in Linguistics (1966) from the Leningrad State University. He joined the Department of Linguistics at the University of Delhi in 1966 where he served with distinction until his death. He had undertaken (in-between) a three year stint as Professor at the Central Hindi Institute, Delhi. Even today he is remembered as one of the major architects of the Department of Linguistics, University of Delhi and the Central Hindi Institute. In 1968 he was awarded the Ford Foundation Postdoctoral Fellowship to carry out research at UCLA. During the 20 years he worked at the University of Delhi, he taught and guided research, undertook several research projects, participated in a large number of national and international seminars, and published extensively in English, Hindi, and Russian. He was the UGC National Professor for a year and was a visiting professor at different universities in the US and Italy. He was often invited as an expert consultant by various international organizations including UNESCO, Paris (1975) and the United Nations University, Tokyo (1982). It is no exaggeration to say that many of Srivastava's students hold major teaching or research positions in the discipline today.

Thanks to his wife Bina Srivastava and her editorial team, we have most of Srivastava's work available in seven volumes of *Studies in Language and Linguistics: Selected Writings of R. N. Srivastava*. The themes of these seven volumes are: literacy, stylistics, bilingualism and multilingualism, applied linguistics, Hindi linguistics, language theory and language structure, and generative phonology. All his work is situated in a dialogic relationship between theory and practice. He valued the innate linguistic potential of every human being and considered multilingualism a normal state of affairs, arguing strongly against the position that multilingualism has a debilitating effect on literacy. He showed how linguistic and cultural plurality goes hand in hand with cognitive richness. At a time when most scholars regarded only formal linguistics as linguistics proper, Srivastava constantly tried to build bridges between theory and practice.

Street, Brian (1943–)

M. Prinsloo

Brian Street's work has had a shaping influence on the development of Literacy Studies over the last three decades. An anthropologist by training, he has developed a grounded and research-focused

approach, concerned with the study of literacy as situated practices in specific contexts, distributed amongst co-participants and embedded within relations of culture and power.

Street's doctoral research was in the area of 'representation' of non-European societies in literature (1975) and he has continued to publish in this area. His perspective in this work is that of seeing 'representations,' (particularly notions of racism, culture, and discourse) as historically specific instances of social and cultural processes and practices, with economic, political, and ideological dimensions that can be studied. He has retained this epistemological focus in his contributions to Literacy Studies. He has confronted 'great divide' assumptions in literacy studies, which have seen literacy as a pivotal and uniform social technology that distinguishes 'modern' from 'other' cultures, and has identified the ethnocentric bias of such work. He has characterized his own work as developing an 'ideological model of literacy,' to distinguish it from what he calls the 'autonomous model of literacy' and to emphasize first, the social nature of literacy, and secondly the multiple and contested nature of literacy practices. His focus on fine-grained local accounts has made his work particularly compatible with a range of scholars from across several disciplines who have a social view of language and its functions, and they have separately and cooperatively contributed a body of work that has become known as the New Literacy Studies.

His ethnographic study of the indigenous 'maktab' literacy practices of the Cheshmehi mountain fruit-growers of north-eastern Iran (1984), together with an extended theorization of literacy as social practice established the framework for his later studies. His book *Social Literacies* (1995) confirmed and elaborated on this earlier work, extending it in various directions, including schooling, adult literacy, and social development concerns.

An edited volume of literacy studies in different cultures and societies (1993) brought together work by anthropologists and sociolinguists from Africa, Papua New Guinea, the South Pacific, Madagascar, the USA, and the UK, to show the rich cultural variation in literacy practices and to show the complex and culturally located links between literacy, identity, and power. This work demonstrated that social practices around literacy vary, but more fundamentally that what is meant by the terms literacy, reading, and writing differs across cultures. Furthermore, it is not just cross-culturally, but within different contexts in the same culture, such as the home and the workplace, and within the same activity that there can be different meanings of reading, writing, and literacy.

Street's work contributes to a broadening of the study of interaction in sociolinguistics, which has primarily been of spoken language and of face-to-face-interaction, to a focus on the multiple forms and purposes that texts and textually linked practices have in social interaction.

In the 1990s he led, contributed to, or supervised research in Literacy Studies across multiple international and local settings, including in Africa and Asia, and has led or participated in a number of funded research programs. These include the ethnographic study of the range of uses and meanings given to literacy in various contexts in South Africa during the transitional period at the end of the apartheid era (Prinsloo and Breier 1996), a study of the everyday writing practices of correspondents in Britain who contributed to the Mass-Observation Archive over decades (2000); research on academic literacies within higher education (Street, Jones and Turner 1999). His perspective on literacy practices in educational contexts stresses particular settings (universities, adult literacy classes) as embodying social practices that are in turn linked to such key concepts as nation, identity, ideology, and discourse.

Street is currently Professor of Language in Education, School of Education, King's College, London University and Adjunct Professor of Education in the Graduate School of Education at the University of Pennsylvania.

Tannen, Deborah

J. Bennett

Deborah Tannen, Professor in the Department of Linguistics at Georgetown University, popularized ideas about gender differences in communication, especially communication between heterosexual American couples in the home, through *You Just Don't Understand: Men and Women in Conversation* (1990). The book argues for a notion of complex complementarity as a feature of the difference between US-based men's and women's language use: access to comprehension between men and women involves recognition of gendered communicative styles encompassing negotiation of interruption, silence, topic focus, and linguistic conventions governing the expression of aggression, desire, and cooperative intent.

Tannen has published 17 books, exploring the interaction of cultural difference and linguistic strategies used by speakers, and listeners, to achieve communication.

Conversational Style: Analyzing Talk Among Friends (1984) and *That's Not What I Meant! How Conversation Makes and Breaks Your Relations with Others* (1986) place emphasis on US based ethnic and regional difference. Many of Tannen's later publications explore gender related stylistic variation within the framework of cultural diversity: *Gender and Conversational Interaction* (1993), *Gender and Discourse* (1994), *Talking From 9 to 5: Men and Women in the Workplace* (1995), and *I Only Say This Because I Love You: How We Talk Can Make or Break Family Relationships Throughout Our Lives* (2001).

Deborah Tannen's work spans several genres. While at least two of her books have been placed on the *New York Times* bestseller list (*You Just Don't Understand* and *From 9 to 5*), and she regularly contributes to popular journals and newspapers (e.g., *Cosmopolitan, Good Housekeeping, New York Newsday, Los Angeles Times,* and *Newsweek*), she is a prolific contributor to academic sociolinguistic debates concerning approaches to understanding power and language. Her arguments move away from the notion of any predictable source of inequity, reflected through communicative style, into a preference for understanding communicative power as a flexible, interactive, diverse negotiation with linguistic strategies, individual context, and the relationship between speakers. In addition, Tannen has published poetry, short stories, and a play, *An Act of Devotion* (in *The Best American Short Plays: 1993–1994*).

Trudgill, Peter John (1943–)

P. Kerswill

Peter Trudgill was born in Norwich, England. He received a BA from Cambridge in 1966, a Postgraduate Diploma from Edinburgh in 1967 and a PhD in Linguistics from Edinburgh in 1971. Trudgill is one of a small number of sociolinguists who began their work in the UK in the 1970s and early 1980s, the others include Lesley Milroy (see *Milroy, Lesley*), James Milroy and Suzanne Romaine (see *Romaine, Suzanne*). Their seminal position in the UK can be judged by the fact that they (with Euan Reid and Robert Le Page) were the instigators of the Sociolinguistics Symposium in 1976, a conference series that is now the leading one in Europe in this field. While these scholars are correctly credited with introducing the 'Labovian' (see *Labov, William*) method and agenda to the UK, Trudgill has

explained (Hernández Campoy 1993: 214) that he sees his intellectual roots as lying in the work of the British creolist and sociolinguist Robert Le Page (see *Le Page, Robert*), whose research is essentially in contact linguistics—a theme later taken up very strongly by Trudgill since the 1980s. Trudgill's work also places him in the tradition of British, European, and US dialectology (cf. Chambers and Trudgill 1998 and Trudgill 1983b). Trudgill is the leading proponent of what Labov has (rather awkwardly) labeled 'secular linguistics,' the study of spoken language in context for the purpose of gaining insight into language structure and change (Trudgill 1978: 11). Like Labov, he sees his own data-based work as contributing to linguistic theory, and this is as true of his Norwich study (1974; with 1988 follow-up) as it is of his much later analyses of a unique 1940s taped corpus of elderly speakers of New Zealand English (Britain and Trudgill 1999, Gordon and Trudgill 1999, Trudgill et al. 2000). The New Zealand corpus is the most significant manifestation of his interest in *dialect contact* since the publication of Trudgill (1986), which is his most substantive contribution to theorizing about language change to date. As with Trudgill (1986), many of his publications report both his original studies as well as syntheses of a wide range of other work. Notable are his publications on language and education, a field in which he had a long-running dispute with the late British sociologist Basil Bernstein (see *Bernstein, Basil*) following the publication of Trudgill (1975a, 1975b). He has also had a long-standing disagreement with the late John Honey over their differing views of the role of Standard English in British education (Trudgill 2000b). In his work oriented towards education and the sociology of language, he often adopts a liberal political stance, as in the final chapter on 'Language and humanity' in Trudgill (2000). Other work in the sociology of language includes Andersson and Trudgill (1990) and Trudgill and Tzavaras (1977). Part and parcel of dialect contact is the social psychological notion of *accommodation* (see Giles and Smith 1979; see *Speech Accommodation*); Trudgill (1986) has differentiated between short-term (immediate, context-bound) and long-term (more-or-less permanent, habitual) versions. An early expression of this idea is his study (1980) of the changing use of American pronunciation by British pop groups from the 1950s to the 1970s. Trudgill is known as a popularizer both of sociolinguistics (2000a, 1st edn. 1974) and of English dialectology (1998a). He has contributed to work on English as an international language (Trudgill and Hannah 1994, 1st edn. 1985).

917

Tucker, G. Richard (1942–)
J. Crandall

Dick Tucker was born May 3, 1942, in Scranton, Pennsylvania. He received his BA in Psychology from Williams College in 1964, and his MA and PhD in Psycholinguistics in 1965 and 1967, respectively, from McGill University in Montreal, Quebec. Upon completion of his graduate studies, Tucker worked for 18 months as a Ford Foundation Consultant to the Philippine Normal College in Manila, where he helped introduce a new specialization in Psycholinguistics into the graduate TESOL program. With Bonifacio Sibayan and Fe Otanes, he also planned and implemented that National Language Policy Survey of the Philippines which focused on the role of education in helping to develop language proficiency (Tucker 1968). He returned to McGill University in 1969, where he began a long career with a triple appointment in Psychology, Linguistics, and Football. Tucker's major research interests have focused on bilingualism, language policy, and the evaluation of innovative language education programs in diverse settings. At McGill, he and Wallace Lambert undertook what was to become a landmark longitudinal study of early immersion in a foreign language (French), the St. Lambert Experiment (Lambert and Tucker 1972). Using multiple measures, including the role of individual differences in second language acquisition in different contexts (Tucker et al. 1976), he and Lambert followed the immersion students through high school (Lambert and Tucker 1979).

During his tenure at McGill, Tucker undertook two additional Ford Foundation Consultancies with the American University of Cairo, Egypt (AUC) and the American University of Beirut, Lebanon (AUB), where he taught courses in the MATESOL program and conducted a number of studies of the language learning strategies of Arab and Hebrew students learning English (Cooper et al. 1979, Scott and Tucker 1974). While in Beirut, he also designed and implemented the English Language Policy Survey of Jordan with Clifford Prator (Harrison et al. 1975).

In 1978, Tucker left McGill to become the President of the Center for Applied Linguistics (CAL) in Washington, DC, the fourth permanent head of CAL. At CAL, he was a frequent consultant to governmental and international organizations seeking to develop effective language polices. In that role, he often called upon institutions to work to develop a language competent United State society, one in which all individuals are provided access to proficiency in English and other language (Tucker 1986), through innovative language education programs such as content-based language instruction and two-way developmental (immersion) bilingual programs (Crandall and Tucker 1990).

Tucker's tenure was co-terminous with the period of the second largest influx of refugees into the United States in the twentieth century, and under his leadership, CAL became the major national source of information and the languages and cultures of refugees from Southeast Asia, Africa, and Eastern and Central Europe.

While at CAL, Tucker maintained a courtesy adjunct professorial appointment with Georgetown University but in 1992 he left CAL to return to fulltime teaching in the Department of Modern Languages at Carnegie Mellon University in Pittsburgh, where he continues to engage in research on second language acquisition through innovative language education programs, including an ongoing study of Japanese immersion students, with Richard Donato and Janis Antonek (Donato et al. 1996). As Head of the Department, he has greatly expanded its offerings and initiated a doctoral program in Second Language Acquisition, with a focus on less commonly taught languages, such as Japanese and Chinese.

Valdman, Albert (1931–)

B. Spolsky

Born in Paris in 1931, Albert Valdman, without doubt one of the leading applied linguists of this generation, was educated at the University of Pennsylvania where he received a BA in Romance Languages and at Cornell University where he earned an MA and PhD in French Linguistics. In the tradition of Cornell-trained applied linguists, his first position was at the Foreign Service Institute of the US Department of State in Washington, beginning his lifelong devotion to ensuring that language teaching be based on a thorough understanding of contemporary linguistics. After a spell at the Pennsylvania State University, he joined the faculty of Indiana University in Bloomington in 1960. Appointed to the Department of French and Italian (where he still directs the graduate program in French Linguistics), he was invited by a group of linguists scattered throughout the university to put together a Department of Linguistics, which he chaired from 1963 until 1968. Now nearly 40 years on the Indiana University faculty, Valdman holds the distinguished title of Rudy Professor of French and Italian and of Linguistics and also serves as chairman of the Committee for Research and Development in Language Instruction and directs the Creole Institute. He has held visiting appointments at the University of the West Indies (Jamaica) and at the University of Nice and taught in summer institutes at Harvard University and the University of Oregon.

Valdman has held Guggenheim, NATO-NSF, Fulbright, and Senior Fulbright Research fellowships. His research and publications span a broad range of areas in applied and descriptive linguistics, including second language acquisition, foreign language teaching, pidgin and creole studies (he has had a major hand in developing research and teaching in creoles), and French linguistics (he is one of the pioneer researchers in the area of the study of French outside of France, especially in the Americas).

The author or editor of more than 40 books, Valdman co-edited the *Learner's Dictionary of Haitian Creole*, hailed as an unequaled resource for Americans who seek to learn the language. Among his major books or edited volumes are: *Trends in Language Teaching* (1964), *Le français hors de France* (1979), *Haitian Creole–French–English Dictionary* (1981), and *Bien entendu! Introduction à la phonétique française* (1993). In addition to publishing more than 200 articles and reviews in major journals in linguistics, he has been involved in the preparation of foreign language materials, including a high school French series and beginning French college textbooks. He is founder and editor of the influential journal *Studies in Second Language Acquisition* and a review editor of the *French Review*.

Valdman has made significant contributions to the profession of educational linguistics as well as to creolistics. He served eight years as secretary treasurer of the American Association for Applied Linguistics. He played a crucial role in integrating American applied linguistics into the international association, serving for six years as president of AILA, the International Association of Applied Linguistics. He has been president of the American Association of Teachers of French.

Valdman has been named Commandeur dans l'Ordre des Palmes Académiques of France, and received an honorary doctorate from the University of Neuchâtel.

Van Name, Addison (1835–1922)

G. G. Gilbert

Van Name was born in Chenango, near Binghamton, New York, and died in New Haven, Connecticut. 'His father owned a sawmill and was interested in the shipping on the canal' (*Dictionary of American Biography* 10, 1936: 201). He graduated at the head of his class with a BA from Yale College in 1858. From 1859 to 1861 he traveled in Europe and studied at the universities of Halle and Tübingen. Van Name was appointed instructor in Hebrew at Yale in 1862, and librarian in 1865. In 1867 he married Julia Gibbs in Berlin; they had three children. His wife was the daughter of Josiah Willard Gibbs

(1790–1861), one of the best known American orientalists, linguists, and librarians of his day; her brother, Josiah Willard Gibbs Jr. (1839–1903), was a noted mathematician and theoretical physicist with close links to Germany and an international following.

Van Name was one of the founding members of the American Philological Association in 1869; William Dwight Whitney read his paper 'Contributions toward a grammar of the Creole dialects of Hayti and Louisiana' in his absence at the first meeting of the Association in that year.

Van Name served as head of the Yale Library for 40 years, building up its collections from 44,500 to nearly half a million volumes and manuscripts 'at a time when little money was available for books or service, but the most striking thing ... is not their number but their quality' (*Dictionary of American Biography* **10**, 1936: 202). Phelps (quoted in Schiff 1978: 534) said, in 1918, that he was 'probably the most skillful buyer of books on earth.' In 1876 Van Name was active in the formation of the American Library Association. Remarkable was his acumen in acquiring books for Yale in and about Chinese and other far (and near) eastern languages. Although his 'creole period' was relatively brief, his methods of study and his insights into the origin and development of those languages were well in advance of their time.

Van Name devoted but a short period of his life to the study of pidgin and creole languages; nevertheless, he introduced a method of study which was unusual in mid-nineteenth-century creolistics—the questioning of linguistic consultants located fortuitously at the researcher's place of residence, persons who provided linguistic data that could be supplemented and corroborated by printed materials, the aim being a comprehensive overview of a scope that no one had thought of attempting up to that time. Van Name himself states that J. J. Thomas's 1869 grammar of Trinidadian Creole French (Van Name 1869–70a: 13) first induced him to begin his own research on creole languages. He describes his local consultants as:

(a) ... 'a young man, who between the age of seven and fourteen (he is now eighteen) lived in Hayti, and has a good command of the Creole';

(b) a 'young man, ... , recently from St. Thomas ... born in Havana, but since his sixth year [he] has lived in St. Thomas, and speaks, besides the French, also the Dutch and Spanish Creole, all three with great readiness ... [and] has also visited nearly all the West India islands, and can speak from personal observation of the limits of the several dialects';

(c) two ex-slaves and a free black, two of them native speakers of Louisiana Creole French, from the vicinity of New Orleans (Van Name 1869–70b: 127).

Modern 'substratophiles' are unhappy with Van Name's emphasis on general principles of development, rather than on specific substratal influences in the formation of the creoles (e.g., Holm 1988: 24–7). Other contemporary researchers hail him as the founder of scientific creolistics (e.g., Stolz 1986: 14). Even the most critical commentators (e.g., Goodman 1964: 111–3) agree that his use of consultants, the taking into account of a variety of creoles with French, English, Portuguese, and Dutch lexical bases, and his recognition of the creole hallmark of unexpected similarities of patterning (whatever their provenience) and, at the same time, of an unusual amount of variation (a term which Van Name uses himself), guarantees him a significant place in the launching of creolistics as a science.

Voloshinov, Valentin Nikolavic (1895–1936)

D. Brown

V. N. Voloshinov was a Russian researcher who was part of intellectual and academic circles in Leningrad during post-revolutionary Soviet Russia. He was a close associate of M. M. Bakhtin (see *Bakhtin,*

Mikhail M.) and N. Medvedev who were semioticians working on literary criticism. Voloshinov's work on philosophy of language provided a critique of de Saussure (see *Saussurean Tradition and Sociolinguistics*), while his work on psychology provided a critique of Freud. His research concerns were for the areas of cultural inquiry explicitly not dealt with by Marxist theory (see *Marxist Theories of Language*) and his work and intellectual activity represents the critical inquiry that flourished in the newly established Soviet state until the Stalinist period of 1929. Bakhtin and Medvedev, his closest associates, were victims of Stalin. Bakhtin was sent into internal exile and only 'rehabilitated' in the 1960s and Medvedev was murdered in Stalin's purges in the 1930s. There is some doubt about the actual date and cause of Voloshinov's death but some evidence that he died of tuberculosis, which he had suffered from all his adult life.

Voloshinov's two significant works were *Marxism and the Philosophy of Language* (1973) and *Freudianism: A Marxist Critique* (1976). Both of these critiques dealt with language. The former is a systematic critique of Ferdinand de Saussure's *Course in General Linguistics*. Voloshinov's critique does not accept the distinction between langue and parole and identified and rejected the Cartesian rationalism that formed the basis of Saussure's thesis. Voloshinov considered the verbal sign a speech act which involved a speaker or writer and a listener or reader. Contrary to de Saussure, parole was an important feature of linguistic concern. His perceptions of the role of the verbal sign paralleled those of the semiotician Charles Sanders Pierce. Voloshinov believed that inner speech was like a dialogue and that linguistic understanding was intrinsic to an understanding of social psychology. His work concentrated on an understanding of reported speech as discourse as just one example of a focus for linguistic study.

Language analysis and understanding of signs was inseparable from ideology for Voloshinov. He believed that the verbal sign was a constant area of class struggle and signs consistently change their meaning socially in relation to changing social contexts. He saw the desire to stabilize the nature of meaning and control the use of signs as a consistent feature of the ideology of dominant social groups (see *Dialogism; Ideology*).

His work fell from any form of public attention after its initial appearance and was unknown in the West until Roman Jakobson cited his work positively in 1957, which led to its translation and reception during the 1970s. Some confusion as to the authorship of *Marxism and the Philosophy of Language* arose in the early 1970s. After an occasion to celebrate the 75th birthday of M. M. Bakhtin (the leader of the intellectual circle and its only survivor at the time), a speaker claimed that the work of his closest associates Medvedev and Voloshinov was really the work of Bakhtin. This produced a controversy known as the 'author's controversy.' However, most writers believe that, as no evidence has emerged, respect for the circumstances of the authors Medvedev and Voloshinov's difficult life circumstances and the historical period demands that we currently accept that Voloshinov was the author of this significant work.

Weinreich, Uriel (1926–67)
T. Hill

When Uriel Weinreich died, aged 41, he left a record of remarkable distinction in three diverse fields: Yiddish studies, linguistic geography and sociology, and semantics. Born in Vilnius, the main center of Ashkenazic Jewish culture, he was the son of the Yiddish scholar Max Weinreich, who in 1940 took the family to the USA, joining the faculty of New York City College. Uriel Weinreich studied, and later taught, at Columbia University, graduating with a PhD in 1951 and going on to become the first Atran

Professor of Yiddish studies, chairman of the linguistics department, and joint editor of *Word*.

Weinreich stimulated and contributed to modern Yiddish studies in many ways, beginning early with the textbook *College Yiddish* (1949). He founded and edited the collections of occasional papers entitled *The Field of Yiddish* (1954), and with his wife Beatrice Weinreich published the bibliography *Yiddish Language and Folklore* (1959). In his *Modern English/ Yiddish, Yiddish/English Dictionary* (1968) his

921

theories on systematic lexicography found concrete application, including the definition and application of the distinctive Yiddish register system. At the time of his death he was engaged upon the *Language and Culture Atlas of Ashkenazic Jewry*, based on data on their ancestral communities gathered from American Yiddish speakers.

Weinreich's doctoral thesis was on language contact, supervised by A. Martinet, with guidance during a year's field research in Switzerland from J. Jud and E. Dieth. Published as *Languages in Contact* (1953), it presented a systematic framework for categorizing mutual influence and mixing between languages, and quickly became a recognized basic text. The comparison of (mainly phonological) systems between dialects was already accepted practice in many surveys, though rejected by others, Weinreich's article 'Is a structural dialectology possible?' (1954a) expounded its theoretical basis, and initiated a discussion that received interesting contributions from, among others, W. G. Moulton and R. I. McDavid Jr (see *McDavid, Raven Ioor, Jr*). In the 1960s, Weinreich's attention turned to the study of linguistic variation and change at the level of idiolect and speech situation, his conclusions being presented in the article, posthumously completed by his pupil W. Labov (see *Labov, William*) and M. I. Herzog, 'Empirical foundations for a theory of language change' (Weinreich et al. 1968).

Weinreich's writings on semantics express his conviction that a valid (and necessarily complex) theory of meaning requires close study of how diverse languages meet the communicative demands made on them, within their cultures, in actual situations.

Accordingly, though he had enthusiastically embraced generative linguistics as a whole, his lecture 'Explorations in semantic theory' (1964; published 1966 in *Current Trends in Linguistics*) was a critique of inadequacies in the Katz–Fodor model, which led to further debate with Katz. Regarding lexicography, Weinreich endorsed the Soviet linguists' view of it as being a distinct discipline, and contributed to it in theoretical papers, as well as in his Yiddish dictionary. His semantic and lexicographical writings were posthumously edited in Weinreich (1980).

Wenker, Georg (1852–1911)
T. Hill

Wenker compiled the first dialect atlas of Germany, and founded the national dialect research center at Marburg. Graduating in Germanic philology, he became a schoolteacher in his native Düsseldorf, and in 1875 began higher degree research on the historical phonology of German dialects, using written sources. The current assumption was that the concept 'dialect' implied an area clearly delimited by linguistic boundaries, within which its specific sound changes had operated uniformly in accordance with neogrammarian principles. When his sources failed to give this clear picture, Wenker decided to clarify the matter by collecting his own data; and with this modest first step he created the method of

inquiry, and the questionnaire, on which ultimately the dialect atlas of Germany would be founded. He drew up a set of 40 sentences, composed so as to illustrate phonological and morphological points, and circulated them to primary school teachers throughout the Düsseldorf district, for translation into each local dialect using ordinary German spelling conventions (a notion familiar from its application in dialect verse, etc.). The project was successful, and the results, published as *Das rheinische Platt* (Düsseldorf 1877, repr. as *Deutsche Dialektgeographie* No. 8, Marburg 1915), revealed *inter alia* the 'Uerdingen line' (*ik/ich*), which is the northernmost limit of the High German soundshift,

and was the first isogloss of the 'Rhenish Fan' to be discovered.

Appointment to an assistant librarianship at Marburg University enabled Wenker to extend his survey into the Rhineland and Westphalia, then, with the support of the Prussian Academy of Sciences, to all north and central Germany, of which the atlas was published in 1881. Wenker now envisaged an atlas of all Germany, and received much scholarly support, but realized that a properly funded and staffed survey would be essential. In response to his appeal for official sponsorship, in 1887 his survey became a German state institute, with Wenker as director and two assistants, one of whom was F. Wrede; and the still outstanding southern region was surveyed. From now on collection and research were funded, but under two onerous conditions: publication of the atlas was postponed indefinitely, and Wenker himself was to abandon research and confine himself to mapmaking. By now a self-taught cartographer, Wenker selflessly accepted this burden. He had decided that each questionnaire item should be separately mapped, and, Germany being divided into three regions, he and later Wrede compiled a total of 1650 maps.

The further history of the atlas, the controversy with O. Bremer, and the theoretical achievements of the Marburg School are discussed in the article on Wrede. Wenker's own life work had shown that an indirect inquiry, intelligently framed and with a dense coverage, yields meaningful and accurate data (though this view is even now not accepted universally), and his method provided a model for numerous later surveys. His results constituted a significant contribution to the dialect boundary controversy.

Whorf, Benjamin Lee (1897–1941)

J. H. Stam

Benjamin Lee Whorf was an amateur linguist who speculated on the relation of language to culture and thought. He is associated with the so-called 'Principle of Linguistic Relativity' or 'Sapir–Whorf Hypothesis' (see *Sapir–Whorf Hypothesis*).

Whorf was born in Winthrop, Massachusetts, April 24, 1897. His parents descended from early American settlers and his father, Harry Church Whorf, was a commercial artist, stage designer–director, and amateur geologist.

Benjamin exhibited a comparable range of curiosity as a youth and graduated from Massachusetts Institute of Technology in 1918 with a BS in Chemical Engineering. In 1919 he was hired by the Hartford Fire Insurance Company as a fire prevention engineer, then a field without academic recognition. Equally new was Hartford's notion that fire inspection and prevention could be a customer service, and Whorf became the recognized expert in this area. He ultimately became assistant secretary of the company, which generously allowed him leave to follow his linguistic and anthropological interests. He worked there until his death from cancer on July 26, 1941. He and his wife Celia Inez Peckham had three children.

An autodidact in linguistics, Whorf began to study Hebrew in 1924, inspired by Fabre d'Olivet's *La langue hébraïque restituée* (1815–16), a work that revived a kabalistic conceit which saw in Semitic sounds and characters mystical meanings. His original motivation was a desire to reconcile modern science with biblical authority: he was brought up Methodist Episcopal, had questioned the theory of evolution, and completed a lengthy manuscript on science and religion in 1925.

Whorf expanded his interests to study Aztec and then Mayan hieroglyphics. Using the collection at the Watkinson Library in Hartford, Whorf extended his pursuits to anthropology and archeology. By 1928 he was working at many other collections in the northeast; he has begun correspondence with scholars of ancient Mexican language and culture; and he published his first article, 'An Aztec account of the period of the Toltec decline.' Whorf started attending scholarly conferences and delivering papers. Although he did not accurately decipher Mayan ideograms, he correctly proposed that they were a system for writing spoken language. In 1929–30 the Social Science Research Council granted him a fellowship, which allowed him to visit Mexico and do further study of Mexican languages.

In 1931 Whorf began to study with Edward Sapir (see *Sapir, Edward*), the prominent anthropological linguist and student of Franz Boas (see *Boas, Franz*), who had come to nearby Yale University. Although he remained an amateur, Whorf now worked in the company of leading professional linguists and found particular resonance between his own ideas and those of Sapir. His study of Hopi, begun in 1932, led to his fullest formulations of the theory that different languages express different understandings of the world, the so-called 'Linguistic Relativity Principle,' particularly in 'Some verbal categories of Hopi' (1938) and 'The relation of habitual thought and behavior to language' (1941).

Whorf was a popular lecturer and wrote accessible versions of his thesis in *Technology Review*—'Science and linguistics' (1940), 'Linguistics as an exact science' (1940), 'Languages and logic' (1941)—and in the *The Theosophist*—'Language, mind, and reality' (1942).

Williams, Glyn (1939–)
D. Brown

Glyn Williams is a Welsh sociologist who has developed a sociological critique of sociolinguistic theory and practice. His research deals with questions of language and social identity in Wales and has led to a critical appraisal of the theoretical assumptions in sociolinguistic writing. His work searches for a consistency of theory and method in the way that sociology deals with language.

Williams was born in Wales in 1939 and received his education at Brunel, completing his PhD at the University of Wales. He was appointed as a lecturer in the department of Sociology and Social Policy at the University of Wales, Bangor in the 1970s. He is currently attached to the Research Center Wales, at the University of Wales, Bangor where he is a reader.

His interest in Welsh identity began with an investigation of the Welsh émigré community in Patagonia, which resulted in the publishing of a historical study of Welsh colonization in 1975 and a bibliography on the topic in 1980, followed by a book *The Welsh in Patagonia* in 1991. He edited a book on social and cultural change in contemporary Wales in 1978.

This was followed by an edited collection on the sociology of the Welsh language in 1987. His language interest has lead to a significant theoretical text, which engages with the normative premises of much of sociolinguistics entitled: *Sociolinguistics: A Sociological Critique* (1992).

Following this, his most recent work on Language Planning has grown out of the European Commission's recent research interest in ethnic and national minorities. Williams has participated in the *Euromosaic Project*, which has funded research on ethnic minorities and minority languages within the wider European context. This resulted in a report for the European commission, done in collaboration with his colleague Deleth Morris at the University of Wales, forms the basis of his most recent publication on language planning and language use. This work contains further developments of his theoretical critique of social theory and methodology on language—for example an important short critique of Bourdieu's *Language and Symbolic Power* (1982) (see *Symbolic Power and Language*).

His interest in theory extends to a recent publication of a book on *French Discourse Analysis* (1998a). William's theoretical influences are broad, ranging from poststructuralist discourse analysis to dependency theory, the work of the Italian Marxist Antonio Gramsci (see *Gramsci, Antonio*) and critical theory. Williams identifies functionalist patterns of thinking as the central weakness in sociolinguistic writings.

He argues that language groups are a relevant feature of social organization and social inequality and that they are underestimated in conventional sociology. His work has been praised as 'exposing the often muddled treatment of minority languages within the social sciences in general and sociolinguistics in particular.' His current and future work on the role of minority language situation in Wales is likely to find a broader influence in the European context.

Wodak, Ruth (1950–)
C. Anthonissen

Ruth Wodak is best known for her work in Critical Discourse Analysis at the University of Vienna, Austria. She is one of a number of scholars (like Fairclough, Fowler, Kress, Van Leeuwen, Van Dijk) who consider discourse as social action and who follow Halliday's (see *Halliday, Michael Alexander Kirkwood*) notion of grammar as a system developed to function optimally in communication. As professor in Applied Linguistics at the University of Vienna, and as a research professor (1999–2002) in the Austrian Academy of Sciences, she has introduced and supervised innovative research into social and political discourses of various kinds.

Wodak is the founder of an approach referred to as Discourse Sociolinguistics, that has developed analytic methods for disclosing and demystifying the ways in which language functions in establishing, sustaining, and challenging power relations. This approach follows principles set out in Critical Theory, a social theory developed by the Frankfurt School since the 1930s. It accepts the subjectivity of researchers, and it recognizes the interdependence of language and context. Thus the necessity of being explicit about the context in which texts are produced and interpreted is accepted.

As editor and co-editor of research publications on nationalistic, chauvinistic, racist, anti-Semitic, and sexist discourses Wodak has contributed to developing new insights into institutional discourse. In the latter part of the twentieth century institutions have become significant instruments for naturalizing social hierarchies through the kinds of discourses they produce and perpetuate. Wodak's interests in sociolinguistics, psycholinguistics, and discourse analysis are reflected in her investigation of political discourses, discourses in institutions such as hospitals, embassies, schools, the printed and broadcast media, Austrian and European governmental organizations, and discourses of stereotyping, prejudice, and discrimination.

Wodak was born on July 12, 1950 in London as the daughter of Austrian-Jewish exiles. The family returned to Vienna in 1953. She studied at the University of Vienna, receiving her Doctorate in Linguistics with highest distinction in 1974, and completing her Habilitation research in Sociolinguistics and Psycholinguistics in 1980. For her doctorate dissertation she was awarded the Theodor Körner Prize, and for her habilitation she was awarded the Kardinal Innitzer Prize. Continued research and development of new approaches, themes, and methods of analysis in the area of critical linguistics was rewarded in 1996 when Wodak received the prestigious Ludwig Wittgenstein Prize from the Austrian *Fonds zur Förderung der wissenschaftlichen Forschung* (Fund for Development of Scientific Research).

With the Wittgenstein prize Wodak established the Wittgenstein Research Center, 'Discourse, Politics, and Identity.' Here a team of researchers uses the discourse-historical method of critical discourse analysis for scholarly reflection on major discourses currently evolving in Europe. The projects focus on the theme of a new European identity based in the recently established European Union. The tension between supranational and national organization of established communities is being investigated. First discourses on unemployment in the EU were collected, analyzed and interpreted; second discourses on neutrality and security were considered. Currently the center's research is directed at discursive construction of alternative memories on the *Wehrmacht* and taboos around this sensitive topic.

Wodak has contributed significantly to our understanding of how social discrimination is discursively constructed and reproduced. Drawing on an enormous source of empirical data collected by researchers in Vienna she shows not only how discourse functions in establishing societal structures, but also how discourse can disclose inequality and injustice and can be applied to restructuring pathological patterns.

Wolfram, Walt (1941–)

C. T. Adger

Walt Wolfram has pioneered research on a broad range of vernacular US dialects, including African American English, Puerto Rican English, Appalachian English, Ozark English, Southern English, American Indian English, Vietnamese English, and most recently, Outer Banks and Lumbee English in North Carolina. Observing the principle of linguistic gratuity whereby 'investigators who have obtained linguistic data from members of a speech community should actively pursue positive ways [to] return linguistic favors' (Wolfram 1993: 226), he has applied sociolinguistic research findings to educational issues (e.g., Wolfram et al. 1999), in teaching, and in making his research findings accessible to the community (e.g., Wolfram and Schilling Estes 1997).

Wolfram grew up in a German-speaking, working-class community in Philadelphia. He earned a PhD at Hartford Seminary in 1969 and pursued a career in theoretical and applied sociolinguistic research at the Center for Applied Linguistics for 25 years. Concurrently, he taught at the University of the District of Columbia, returning linguistic favors to the African American community whose language he began studying as a graduate student. There he trained speech/language pathologists and broadly influenced the field regarding language diagnosis and assessment practices, and normal language behavior in African American Vernacular English (AAVE) speakers. Early in his career, Wolfram published the first descriptive linguistic volume on AAVE (Wolfram 1969). Subsequent work on this dialect has illuminated similarities to Southern English and other regional dialects, and examined the sociolinguistic significance of obscure structures such as [NP$_i$ CALL NP$_i$ V-ING] (*She calls herself saving money*).

In 1992, Wolfram became the first William C. Friday Distinguished Professor in the English Department at North Carolina State University, where he established the North Carolina Language and Life Project for study of that state's richly varied dialects. Theoretical contributions of work on Lumbee English, Ocracoke English, and Hyde County Anglo-American and African American English dialects include explanations for the development and maintenance of vernacular dialect norms based on linguistic, sociohistorical, sociolinguistic, sociopsychological, and ideological factors. He introduced the notion of endangered dialects to the language endangerment canon. Wolfram and his students have presented sociolinguistic descriptions of North Carolina dialects to schoolchildren in dialect awareness curricula, constructed a prize-winning dialect museum exhibit for the Ocracoke Preservation Society, and developed books, videos, CDs, and audiotapes that report the research for lay audiences.

Wolfram's contributions include dialect research that is broad in scope but also particular and integrative, as well as unflagging commitment to increasing public awareness of the role of vernacular dialects in society. At the same time he has served the profession in leadership (most recently as president of the Linguistic Society of America for 2001) and teaching positions beyond his institution.
